On December 3d the patient had a severe attack of colic, beginning early in the morning and lasting until 6 p.m. At that time she had an intense pain and desire to go to stool, and then passed the gallstones exhibited by the author in connection with this case. The patient collected the one hundred and thirty-two gallstones shown, and asserted that quite a number escaped from the bowl of the water-closet before she realized what had occurred. A few small stones were passed in the succeeding days, but since the 7th of December none had been noticed; the patient had been entirely free from colic; the pigmentation of the skin was disappearing, and her general health was improving in every respect. Upon examining the gallstones in the bottle, two of them were found to be very much larger than the others. The writer’s idea was that the cystic duct was occluded by the two large stones, the smaller ones being imprisoned above them in the gall bladder. It was also thought that in the beginning the common duct was occluded by the greenish thick mucus that was passed with the feces at times in the early treatment of the case.

The Dangers of Caffeine.—According to the Indian Medical Record for July 12th, the popular idea of the harmlessness of caffeine has been dealt a blow by Dr. M. K. Zenetz, extraordinary professor of therapeutics at the faculty of medicine at Varsovie, who shows that it may cause sudden death by arrest of the heart in systole. He cites three cases: One was that of a woman free from any organic lesion, who, feeling indisposed, took every two hours a powder containing thirty centigrammes (4.5 grains) of citrate of caffeine; after the fifth dose she fell down in a state of syncope, from which she was roused with difficulty. After recov-
ory she continued to take caffeine, and died suddenly after taking another five powders. The second was a case of pneumonia. The patient died suddenly after taking in the space of two days one gramme twenty centigrammes (eighteen grains) of citrate of caffeine. The third was a woman suffering from nephritis. She died suddenly when taking caffeine.

In these three cases the heart was found at the autopsy to be so firmly contracted that it could with difficulty be cut with a scalpel. In other cases also serious symptoms have been observed. When the caffeine is stopped it continues to appear in the urine for from ten to fifteen days. It is, therefore, eliminated slowly by the kidneys, and its dangerous effects are due to its accumulation in the system.

The Vomiting of Pregnancy.—Bu ford (Memphis Lancet, July) says that the observable mechanical phenomena of emesis are solely those referable to the stomach as a muscular viscus, and are shown in proportion to the degree of irritation, central or peripheral, first in the sensation of pain or nausea, and secondly in the reversed peristalsis of the stomach, producing the ejection of its contents. Vomiting is then the result of peripheral or central irritation, as is seen from the taking of improper food on the one hand and the results of epilepsy, or rather of the causes producing epilepsy, and of head injuries on the other. Since nausea and emesis of pregnancy often occur when the stomach is empty, and especially in the morning, after the contents of the stomach from the previous day have been passed into the bowels, the idea of a reflex from peripheral irritation of the pneumogastric nerve may be entirely eliminated. This forces us to the conclusion that there must be a central cause for it, which from the very nature of the conditions must be a chemical substance, brought by the blood current in direct contact with the vomiting centre, which is in the nucleus of the vagus, in the floor of the fourth ventricle.

To explain this he says: The normal result of conception is cell multiplication, the feundated cell or ovum elaborating its constructive material from that presented to it by the blood. This cell proliferation takes place in the fetus, in the walls of the womb, and in the mother, depositing fat for future use. Cell metabolism is abnormally active in both the embryo and the mother, resulting in anabolism. Constructive metabolism is possible only by the cell appropriating to itself suitable material for its growth. Whether the cell by its inherent power appropriates the proximate principles as such, which are presented in the blood, or by its catalytic force splits up the molecules, and then recombines them, there are left in the blood current certain substances, excrementitious in character, both free and combined, which during cell metabolism have given up some one or more of their elements, especially oxygen, nuclein, and the sulphur and phosphorus compounds. There also is pari passu with anabolism, catabolism. During this process nuclein acid is liberated, which in turn is split up into uric acid and albumin, the albumin probably recombining, and the uric acid is supposed to be eliminated through the maternal emenatures. The residue left in the maternal blood current is chemical units which combine and recombine according to biochemic laws to form intermediary and end products, to be excreted or to perform further duties in the economy, and only become deleterious when they accumulate or are produced faster than they are eliminated. Then during all mitosis we find liberated uric acid in proportion to all metabolism. During the first four months of pregnancy both foetal and maternal metabolisms are most rapid, and it is usually during this period that nausea and emesis are most distressing. This period of active development of the fetus and deposition of fat by the mother is the time that the heaviest demands are made for material for cell growth, and consequently there exists increased desire for food by the mother. Nature makes provision for the normal elimination of these by-products or leucomaines per vies naturales, and this is why we see the passage of so much urine during this period. If this excessive urination were due to pressure against the bladder by the growing uterus, we should have a smaller quantity passed at night, but the kidneys secrete at night as well as by day, and we find the bladder responding to the irritation of the acid urine at night as well as during the day. When cell metabolism is active and heavy demands are made for material, overingestion of food results, and we have then what Ewald calls hyperhydrolorxia, and this results in transitory nephritus, which is first shown by hypersecretion and then by hyposecretion of urine. During this temporary overloading of the digestive tract, both ptonamines and leucomaines are formed, which depress the nerve centres. Foetal metabolism is progressing, as is also maternal deposit of fat; and toxines are formed in abnormal quantities and accumulate as a result of defective elimination, the temporary or transient nephritis incapacitating the organs for the full discharge of their physiological functions. This cycle of vicious influences is repeated day after day in various degrees. Emesis and nausea are worse on awaking in the morning, both as a result of the centres responding then more readily to irritations and also because during the quiescence of the functions of the skin and bowels there has been an accumulation of this toxine. As to the nature of this substance, he dare not hazard an opinion, further than to say that probably it is an alkaloid of undetermined chemical formula, a leucomain of the uric-acid group, which acts centrally on the vomiting centre as does apomorphine. The suggested treatment consists of (1) thorough lavage of the stomach three times daily with alkaline antisepitic solutions; (2) baths and massage to enable the skin to assist the kidneys; (3) free exercise in the open air; (4) diet of proper quantity and quality.

A Lipoma of the Uterus.—A unique case is abstracted in the British Medical Journal for August 5th: Brünings (Monats. f. Geburts. u. Gynäkologie, May, 1899) removed a tumor of the size of a child’s head from the anterior wall of the uterus of a woman, aged fifty-five years. On section, its cut surface appeared bright yellow and soft, and a little fluid exuded, which was found to be full of fat globules. Brünings made out that the tumor was by origin a myoma. He detected every stage of fatty degeneration of plain muscle cells, as well as areas of pure adipose tissue and of perfect muscular fibres. This change was also noted by Amann, who denied that the fat had simply infiltrated the tumor. The growth was therefore a lipomyoma of the uterus. Brünings has not found in medical literature any record of a case of this kind.

Entozoa as a Possible Source of Endometritis.—E. M. Simons (Centralblatt für Gynäkologie, No. 26, July 1, 1899; British Medical Journal, August 5th) noticed in examining a woman, aged forty-two years and six
months, and suffering from rupture of the perinaum and tear of the cervix, that the secretion from the uterus had a peculiar aromatic odor, and that the erosion had a very pale livid color. On the vaginal portion was seen an oxyuris vermicularis, about a centi- metre and a half in length, and from the cervical canal another smaller one was extracted. There was neither vulvitis nor colpitis in this case, but possibly the endometritis which existed might be ascribed to the parasite. The patient had long suffered from rectal irritation.

Proceedings of Societies.

AMERICAN LARYNGOLOGICAL ASSOCIA- TION.

Twenty-first Annual Congress, held in Chicago, Monday, Tuesday, and Wednesday, May 22, 23, and 24, 1899.

The President, Dr. William E. Casselberry, of Chi- cago, in the Chair.

The Sphere of Laryngology.—The president read his annual address thus entitled. (See page 323.)

Is the So-called American Voice due to Catarrhal or Other Pathological Conditions of the Nose?—This was the title of a paper read by Dr. John W. Farlow. (See page 327.)

Dr. G. Hudson Makuen, of Philadelphia: I was greatly interested in Dr. Farlow's paper. The subject is one to which we, as laryngologists, should give more attention. It is a common belief among teachers that doctors know very little about voice and speech, and it would seem that specialists in our line should give at least a sufficient amount of attention to the subject to be able to direct the training of the human voice. The high-pitched, nasal American voice, as has been said, is often commented upon, and I believe that one factor in the cause of the high pitch is our Ameri- can energy and push. Professor William James has written an article on the Gospel of Relaxation, and if we were to follow the precepts that he advocates there would be less of this quality of voice. He says that we pride ourselves on our ambition, but instead of its being a matter for commendation he believes that it is fast growing to be a national calamity.

I suppose that the direct or immediate cause of the nasal voice is a low-hanging palate during speech; the vibrations rise into the postnasal space and nasal cham- bers, and the result is a nasal voice. Obstructions in the anterior part of the nose have very little to do with it. If I am right in supposing a low-hanging palate to be the direct cause of nasal voice, then the proper treatment would be that which would stimulate the levator muscles of the palate and cause it to be drawn upward and backward against the pharyngeal wall during vocalization.

It is an easy matter to teach the voluntary control of the levator palati muscles, and thus by repeated voluntary contractions to so develop these muscles and their nerve supply as to bring the palate into correct position during speech, and thus shut off the vibrations from the nose and diminish the nasal character in the voice.

Dr. T. A. DeBlois, of Boston: One is perhaps led to believe that in the tone of the voice there may be a great deal in racial conditions. We all speak of the guttural German or Russian voices; of the vibratory nasal tones of the French, and the high-pitched Yankee voice. We also hear a great deal of the beautiful, low English voice, and yet apparently mouth-breathing is so prevalent among the English that it is a favorite subject for caricature by the French illustrated papers, and in almost all of these papers you will see my lord and lady (English) marching through the continent with their front teeth exposed like those of a rodent. Among the English, the nose of the higher classes is very long, and probably very little air passes through it ex- cept in the act of sneezing. Many of the English people take snuff, and notwithstanding all this the English voice is very sweet in contradistinction to that of the American. This bears out what Dr. Farlow has said as to the little effect the condition of the nasal passages has upon voice production. It would therefore seem largely a matter of education, or the fact that the child grows up among people who all use their voices in the same way.

Dr. John O. Roe, of Rochester: The influence of the accessory sinuses on the voice has not been men- tioned by Dr. Farlow and other speakers, yet these cavities have much to do with the tone of the voice. They are the resonant chambers of the head, and the character of the voice depends to a great degree upon their size, shape, and position. Any one studying these cavities with reference to their influence on the voice will be impressed by their lack of uniformity, and will readily see the explanation for the modification of the voice which the great variations in these resonators cause. The reason, therefore, why obstructions in the anterior nasal chambers have so little effect upon the voice is that they do not cut off the resonance of the accessory sinuses; whereas obstructions in the pos- terior nares cut off the resonance of these sinuses and very materially alter the tone of the voice, as illus- trated by the effect of adenoid growths. As the essay- ist has said, the aptitude of children to imitate the sounds they hear, and particularly the voices of those they are accustomed to associate with, will have a major influence on the character and intonation of their own voice; and, furthermore, I believe that the language used has also a great deal to do with the in- tonations of the voice. The continental languages, the German, for instance, in which the guttural sounds and consonants predominate, tend to produce voices that are, as a rule, pitched on a lower key and deeper in tone than others, whereas those languages in which the enunciation of the vowels predominate, the French, for instance, tend to produce voices that are pitched higher and are not so deep and resonant.

Dr. Makuen: It seems to me the best proof of the fact that obstructions in the nasal cavities have little to do with nasal voice is that one may easily imitate the nasal voice without changing the anatomical condi- tion of these cavities. We can use the nasal voice with- out changing these structures. The change is entirely in the musculature of the vocal and oral mechanisms of speech. (Here Dr. Makuen gave an example of nasal twang in his own voice by relaxing his levator palati muscles.)

Dr. A. W. de Roaldes of New Orleans: The results we obtain in changing some voices that have been ac- quired largely by faulty habits are strong proofs of what can be done by proper vocal exercises and careful
training, either in changing or lowering the tone of the high-pitched voice that Dr. Farlow has been talking about. Certainly, the high-pitched falsetto voice can be changed in the course of a few hours by proper vocal training. There is no question but that the American voice is due largely to faulty habits, which can be overcome by proper vocal exercises and such treatment, regardless of any local effect of the nose, mentioned by the essayist, and understanding that it is the result of imitation. In many communities we have important reasons for this habit in fast living and in the way that people have of forcing and impressing their views on others in a loud manner. This is a question largely of race and education. In the South we do not hear the high-pitched voice very frequently, and I think it is the result, to a great extent, of miscegenation, a mixing of the races, and of habits of life. We do not rush as much as you do up North, and I do not think we meet with so many of these voices in the South. Besides, I do not think the negro race is much addicted to the use of these tonalities. So I think it must be a question of race and of localities due to education. To repeat: Proper vocal exercises and careful training ought to overcome or at least improve this defect, which seems to be a characteristic in certain parts of our country.

Dr. Thomas Hubbard, of Toledo: I am surprised to have heard nothing in regard to the influence of noise, especially in our cities. This is an age in which one half of the population resides in cities, and it is remarkable how we tolerate loud noises. We are forced to cultivate the shrill, carrying voice in speaking on the streets and on street cars, and too often in our very homes. The ear becomes less sensitive to and less critical of the more delicate qualities of the voice in the constant presence of a noisy environment.

Dr. Farlow: With reference to what was said by Dr. Makuen as to the low palate being a factor in the production of the nasal voice, it seems to me that it is due to the lack of use of the palate, and not that the low-hanging palate originally caused the nasal voice; but the nasal voice persisting, the palate, being little used in helping to form the voice, gets out of function, as it were, and consequently the voice becomes more nasal, and continues so.

As regards the accessory cavities, referred to by Dr. Roe, I hardly feel that they have any influence, for the reason that nasal voices are so common here in young children in whom the accessory cavities are practically undeveloped. The frontal and maxillary sinuses are developed but little in young children, in whom the nasal voice is marked. Another point referred to by Dr. Roe is the question of language. The English language is spoken in Canada, India, Australia, England, and the United States, but it is in our own country almost exclusively that the nasal voice is found.

As regards what Dr. Hubbard said about noise having to do with the nasal voice in our cities, I will say that the twangy voice is quite as common in small country New England towns as in the noisy cities.

Dr. Roe: Would not a lack of development of the accessory sinuses in children account for the peculiar high-pitched voice, and as the sinuses developed the voice would become lower in tone; the peculiar twangy voice would disappear with the enlargement or development of the accessory sinuses? Furthermore, would not nasal obstructions also account for cutting off the nasal resonance in the accessory sinuses?

Dr. Farlow: American children do not have smaller accessory cavities than the children of other countries, but my paper endeavored to show that they are more prone to nasal voice than children of other nations. (To be continued.)

Ever since the days of Hippocrates pressure and heat have been popular means of arresting hemorrhage. Surgeons, however, have not depended on these means alone, but have regarded the ligature as their greatest safeguard, employing pressure or heat when ligatures have not been applicable. But Dr. Skene would have us do away with the ligature entirely. There is no doubt that ligatures and sutures frequently prevent the prompt healing of wounds and give rise to sinuses, abscesses, and pain from compressed nerve ends, but it is doubtful if surgeons will soon give them up. The author's ideas were originally suggested by the work of Dr. Thomas Keith, who years ago treated the pedicle in ovariotomy by means of the clamp and cautery.

About two years ago the author first published a paper on the advantages of the electric clamp in ovariotomy, and since that time he has invaded nearly all the fields in surgery with this method, without a secondary hemorrhage. The electric clamp which he recommends so strongly is not, however, the only rival of the ligature. Tuffier's angioplaste has met with favor in the hands of a few, especially in crushing the pedicle in ovariotomy. We often see its principle demonstrated in injuries by which a part is carried away. In such cases hemorrhage rarely follows unless the wound is interfered with. Heat, to be of value as a hemostatic, must be nicely controlled, and this requires not a little experience with the ingenious instruments at hand, while pressure, without ligation, can not be done.

The concluding chapters of Dr. Skene's book are devoted to asepsis and antisepsis, and deal incidentally with much of a miscellaneous character, such as sanitary hospital construction, hospital plumbing, heating, ventilation, and room disinfection. The work contains a great deal of interesting matter and is well worthy of careful reading.

The exhaustiveness of this work, in particular, will impress all who consult its pages.

Naturally the opening chapters are general in their nature and will bear a thorough reading. In them the whole subject of natural mineral waters is completely discussed. These chapters treat, in order, of the origin...
of springs and their sources of mineralization, the classification of mineral springs, their mode of action, the commercial and synthetic waters, the solid and gaseous components of mineral waters, their therapeutics, and baths and douches.

The greater part of the volume is devoted to a careful description of the individual mineral springs of this country. Each State and Territory of the Union has a chapter to itself, and therein are grouped all its mineral springs. The description of each of these springs is complete and exhaustive and, moreover, of the utmost practical utility. For example, the situation of the spring is exactly described, the railroad or other conveyance by which it is reached is mentioned, the hotel accommodations are set forth, with remarks on the scenery, analyses, and finally information as to the utility of the waters in disordered conditions. When the vast number of mineral springs within our borders is realized an appreciation of the scope of the work may be had, and, as for accuracy, an acquaintance with many of these localities enables us to find no flaw in the description.

The book contains a few selected articles, taken from the numerous and valuable contributions of the writer, which have appeared since the production of the fourth edition of his well-known work on The Surgical Disorders of the Urinary Organs, now out of print.

The text is accompanied by a hundred and eighty-seven illustrations. There are sixteen chapters, corresponding to the original papers, which have recently been carefully revised. Mr. Harrison's writings have always commanded our favorable notice in the past, and we take much interest in his latest addition to the literature of the urinary tract.

Those who recall a previous work by this author, upon the treatment of pulmonary tuberculosis, especially in sanatoria, will have pleasurable recollection of it, and will no doubt gladly welcome this more ambitious volume upon the same subject. The book, briefly stated, is the former work grown more complete.

Chapter i of the volume before us is historical, and chapter ii details the mortality from pulmonary tuberculosis. The third chapter brings to our notice "pathological proofs of the curability of pulmonary tuberculosis," and the fourth the communicability of the disease and its prophylaxis by individual effort. This chapter, indeed, is alarming but none the less truthful. Public prophylaxis is the title of the fifth chapter, and this is one that all hygienists should read, as is the subsequent chapter upon bovine tuberculosis. In chapter vii is detailed the preventive treatment of the disease.

The essence of the volume is comprised in the two following chapters, which deal with sanatoria and the treatment as conducted in them. These chapters are of the utmost interest and value, as is the eleventh, which plans an ideal sanatorium.

The remainder of the volume is composed of a number of brief chapters upon such subjects as aerotherapeutics, exercises, treatment by the pneumatic cabinet, hydrotherapy, and dietetics. As a rule they are not up to the standard of quality exemplified by the earlier chapters.

To those who contemplate a visit to Nauheim this little volume will be invaluable. While it is adapted to the comprehension of the laity, it will afford to the medical man an introduction to the Schott treatment and to readers in general those descriptive features as to locality, access, accommodations, occupation, and expense which are ordinarily the features of the modern guide-book. In view of the recent heightened vogue of the Nauheim treatment, the appearance of this new edition is most timely.

BOOKS, ETC., RECEIVED.

General Pathology of the Science of the Causes, Nature, and Course of the Pathological Disturbances which Occur in the Living Subject. By Dr. Ernst Ziegler, Professor of Pathological Anatomy and of General Pathology at the University of Freiburg in Breisgau. Translated from the Ninth Revised German Edition by Dr. Theodore Dunham, Dr. Edward M. Foote, Dr. Philip H. Hiss, Jr., Dr. Walter B. James, Dr. William G. Le Bontillier, and Dr. Matthias Nicoll, Jr., of New York; Dr. B. Meade Bolton, of Philadelphia; Dr. Leonard Woolsey Bacon, Jr., Dr. John S. Ely, and Dr. R. A. McDonnell, of New Haven, Connecticut. Editor, Dr. Albert H. Buck, New York. New York: William Wood & Co., 1899. Pp. xxiii–598. [Price, $5.]

Practical Anatomy: including a Special Section on the Fundamental Principles of Anatomy. Edited by W. T. Eckley, M. D., Professor of Anatomy in the College of Physicians and Surgeons, University of Illinois, etc., and Mrs. Corinne Beford Eckley, Instructor in Anatomy in the Northwestern University Dental School, etc. With Three Hundred and Forty-seven Illustrations, many of which are in Colors. Philadelphia: P. Blakiston's Sons & Co., 1899. Pp. xii–9 to 485. [Price, $3.50.]

Transactions of the Medical Society of the State of West Virginia, held in Weston, May 17th, 18th, and 19th. Historique des applications pratiques de la phonétique expérimentale. Par M. l'Abbé Rousselot. [Extrait de La Parole.]

Miscellany.

Animal Medicine.—In our issue for March 25th we published a note about Surgery among Birds. Dr. James Weir, Jr. (Denver Medical Times, August), in an interesting article on Animal Doctors and Animal Patients, says that the honeybee when attacked by diarrhoea (a disease to which under certain conditions it is very liable) will immediately begin to suck the astringent juices of the dogwood, poplar, wild cherry, or hickory, and will soon effect a cure of this distressing and often fatal malady. Indeed, such is the intelligence of these little creatures that, in winter, when they become sick with this disease, they will readily drink a decoction of wild-cherry bark if it is placed in the hive. When we remember that the bee's taste is even more discriminating than our own, and that it is by no means fond of bitter substances, this instance of its intelligence becomes all the more remarkable. These insects seem to be aware of the fact that filth is a source of disease; hence, when ill in winter they select a spot as far from the comb as possible, at which all of the sick members of the hive deposit their dejecta. As soon as warm weather arrives the accumulated filth is removed and the spot carefully cleansed. In summer all excrementitious matter is deposited without the hive.

The author next records remarkable observations of the way in which the crayfish deals with its parasitic leeches (histrionicula), and says that many of the higher animals have discovered and use a materia medica that is not recognized by human physicians, but one which seems to be exceedingly efficacious so far as they are concerned. Dogs will seek out and devour the long lanceolate blades of couch grass (Trilicium repens) when they are constipated; horses and mules will eat clay when they have "scours"; cattle with the "scratches" have been seen by him to plaster hoof and joint with mud, and then to stand still until the protecting and healing coating dried out and became firm. He saw a cow not long ago break the thin ice on a pond and treat her itching joints to a mud poultice. Several travelers and hunters of big game declare that they have seen elephants in the act of plugging shot holes with moistened clay! A gentleman recently informed him that a short time ago, after a severe snow storm, he was hunting rabbits, when he saw his house cat plowing through the deep snow some distance in advance of him. He thought at first that she was out on the same business as himself—i. e., rabbit hunting—but soon concluded that something of much greater importance had impelled her to abandon the warm kitchen on such a cold and inclement day.

He resolved to follow her, which he did for three miles, until she finally entered a neighbor's garden, where, after scratching in the snow, she soon uncovered a bunch of catnip. This she at once proceeded to devour! Surely a great and abiding faith in medicine must have dwelt in the bosom of this animal!

An acquaintance of the author's, a physician, spent the greater portion of last summer at a farmhouse. One day, while walking with the farmer, the latter called his attention to a sow that was confined in a pen. The farmer explained that the animal had been kicked in the abdomen by a mule and that he feared that she would die. The sow seemed to be in great pain and was continually trying to get out of the pen. The physician suggested that the door be opened; that the sow probably had peritonitis and would die anyhow. "The door was opened and immediately the sow proceeded toward a disused spring, situated some distance from her pen. This spring issued from beneath the roots of a large tree, and, the water being strongly impregnated with iron, was not used for potable purposes and was fenced about with rails.

"When the animal arrived at this fence she stopped and began to grunt, noting which her owner let down the rails. The hog walked through the gap, at once entered the shallow depression which formed the bowl or bed of the spring, and lay down in the cool water. Here she remained for five days without taking food, though corn in abundance was placed within her reach. At the end of this time she emerged from her self-elected sanitarium completely cured."

The saliva of mammals, with the single exception of man, seems to have a distinct curative action. Of course, much of the beneficial result following the continual licking of wounds by animals is due to the resulting cleanliness; yet, beyond the mere matter of cleanliness, there is an undoubtedly curative property in their saliva. Dogs, cats, cattle, rodents, monkeys, etc., lick their wounds when they can get at them, and soon effect cures.

It sometimes happens that animals contract wounds on their bodies which they themselves can not get at; then, as Dr. Weir has frequently observed, some good Samaritan in the shape of a fellow dog, cat, or monkey will step in and treat the wounds as though they were personal. His dog Toney is surgeon to all of his other dogs, and, what is more to the point, seems to cure his cases much more effectually and in much shorter time than does his rival in the profession—his master!

The author then records cases in which his dog Toney successfully treated two other wounded dogs, and concludes with describing how a dogfaced ape at St. Louis, in 1889, healed a sore by dressing it with sawdust, while a capuchin in 1889 treated its burned finger with a bread-and-milk poultice from its feeding platter.

A Doctor's Conditions for becoming Physician in Ordinary to Royalty.—The Indian Lancet for July 16th says that Princess Ferdinand, of Prussia, had a
Morphinism
Sanatorium
I
The

The following scene occurred one day. The princess, reclining on a sofa in a splendidly appointed audience chamber, was staring through a magnifying glass at Dr. Heim, who had appeared at her summons.

"Will he step near?" she said; and then continued, "I have heard a good deal of his skill and his large and increasing practice. I have accordingly decided to appoint him my physician in ordinary, and I wish to inform him of the fact myself."

"I thank your Royal Highness for the honor," replied Heim; "but I can only undertake the post under certain conditions."

The princess laughed and said:

"Conditions! I never heard of such a thing."

"Indeed," Heim enjoined; "then it is time you did."

"Well, let me hear what they are."

"The first condition," said Heim, "is that your Royal Highness will never address me as 'he.' That is quite out of date. The king never does it. I do not even style my valet 'he.' The second condition is that you do not keep me waiting so long in the ante-room as you have done to-day. I have no time to lose, and have always as much as I can get through in a day. The third is that your Royal Highness will refrain from staring so at my feet. I cannot come in pumps, but only in boots, and in my ordinary walking-coat. The fourth is that you will not require me to attend you first. I must be allowed to pay my visit according to the nature of the complaint, and in the order of the position of the streets and houses. The fifth is that you will not detain me too long, and require me to talk about the political changes or the gossip of the town. I have no time for that. Lastly, the sixth is that as you are a Royal Highness you will pay me handsomely."

His conditions were most readily complied with.

The New York State Medical Association will hold its sixteenth annual meeting on October 24th, 25th, and 26th in the building of the New York Academy of Medicine. The following-named papers are to be contributed to a discussion on typhoid fever: The Advance in our Knowledge of Typhoid Fever, by Dr. Herman M. Biggs, of New York; The Bacteriology of Typhoid Fever, by Dr. W. H. Park, of New York; The Clinical Diagnosis of Typhoid Fever, by Dr. William Osler, of Baltimore; Statistics of Typhoid Fever at the Roosevelt Hospital for Ten Years, by Dr. W. H. Thomson, of New York; Typhoid Fever in the Massachusetts General Hospital during the Past Fifty Years, by Dr. Revere Fitch, of Boston; Some Phases of Typhoid Fever as seen in Bellevue Hospital, by Dr. A. A. Smith, of New York; a paper (title not given), by Dr. E. G. Jane-way, of New York; Typhoid Fever in Children, by Dr. Abraham Jacob, of New York; The Local (Non-surgical) Treatment of the Intestinal Tract in Typhoid Fever, by Dr. De Lancey Rochester, of Buffalo; The Treatment of Perforation of the Bowel in Typhoid Fever, by Dr. W. W. Keen, of Philadelphia; and Eye Complications in Typhoid Fever, by Dr. A. A. Hubbell, of Buffalo.

On the evening of the 24th, at eight o'clock, there will be a number of communications on Expert Testimony. The following-named gentlemen have agreed to be present and take part: The Hon. Willard Bartlett, Charlton T. Lewis, Esq., William A. Purrington, Esq., and Dr. Theron A. Wales.

The following miscellaneous papers are included in the preliminary programme:

The Operative Treatment of High Myopia by Removal of the Crystalline Lens, by Dr. Charles Stedman Bull, of New York; Abdominal Contusions, by Dr. George D. Stewart, of New York; Animal Products Used as Medicines, Ancient and Modern, by Dr. Thomas J. Acker, of Westchester County; The Value of Operative Treatment in Spina Bifida, by W. W. Reid, of Oneida County; A Report of a Case of Puerperal Septia, and What It Teaches, by Dr. Charles H. C. Childs, of Herkimer County; Some Practical Experiences in Aspesis and Antiseptia in Obstetrics, by Dr. Douglas Ayers, of Montgomery County; Progress of the Science and Art of Obstetrics, by Dr. Florence O. Donohue, of Oneida County; A Brief Summary of the Indications for Operations upon the Stomach, by Dr. Max Einhorn, of New York; Subnormal Temperature, by Dr. Le Roy J. Brooks, of Chenango County; The Mechanics of Voice Production, by Dr. Dwight L. Hubbard, of New York; Report on the Work of the International Gynecological Congress in Antwerp, August, 1899, by Dr. A. Crothers, of Hartford, Conn.; Oesophageal Stenosis, with Surgical Treatment, by Dr. James G. Hunt, of Oneida County; Brief Comments on the Matter Medica, Pharmacy, and Therapeutics of the Year ending October 1, 1899, by Dr. Edward H. Squibb, of New York.
The following-named gentlemen also have promised to contribute papers, but as yet they have not sent their titles to the committee: Dr. Henry Wandle, Dr. John A. Wyeth, Dr. Reginald H. Sayre, and Dr. Thomas L. Bennett, of New York; and Dr. Carlton C. Frederick, of Erie County.

On the evening of the 25th a reception will be given by the association, at the New York Academy of Medicine, to Dr. W. W. Keen, of Philadelphia, president of the American Medical Association, Dr. William Osler, of Baltimore, and Dr. Reginald Fitz, of Boston.

A Pharmacist Punished for Substitution.—The Gazette hebdomadaire de médecine et de chirurgie for July 27th states that a Paris pharmacist was lately fined and imprisoned for substituting cheap drugs for expensive ones in filling prescriptions.

Changes in European Faculties.—We learn from the Wiener klinische Wochenschrift for August 10th that Dr. Karl Ipsen, extraordinary professor, has been made ordinary professor of legal medicine in Innsbruck; that Dr. Lacae and Dr. Senator, extraordinary professors, have been made honorary ordinary professors in Berlin; that Dr. Gumprecht has been made extraordinary professor of legal medicine in Jena; that Dr. O. Bloch has been made ordinary professor of surgery in Copenhagen; and that Dr. Rossoni has been made ordinary professor of medical pathology in Rome.

Superfluous Medical Colleges.—In a newspaper article with this heading, Dr. Charles W. Alden, of Saginaw, Michigan, says: "Many a young man, who might have made his mark in mercantile pursuits, is lured by the glowing accounts sent out by the promoters of inferior schools into entering the medical profession. Knowing nothing of the requirements for a first-class physician, they fall into the trap set for them, and are turned out at the end of a brief course, spoiled for any other career, and not fitted for the one upon which they think they have entered. The country is overrun with the products of cheap colleges. Good articles, of any class, come high. Only cheap goods are cheap. Let a young man aspire, if he is fitted by nature for it, to that most arduous of all professions, that of medicine, and let him carefully count the cost. A four-years' course (after he has had preliminary training) at a first-class medical college will do for him what education can do to fit him for his work. His after success depends upon himself and his ability to follow his chosen calling. But it is an injustice to a young man (as well as to the public) to hold out inducements to enter inferior medical schools, the object of whose existence is to put money in the pockets of the home-made professors who are its promoters."

A Model Camp at the Presidio.—According to the Army and Navy Journal for August 19th, Surgeon-General Sternberg has received from Colonel Charles R. Greenleaf, at San Francisco, a full report on the model camp for volunteers at the Presidio, California. The report says:

"This is now occupied by three regiments, the Second Oregon, First Nebraska, and Tenth Pennsylvania, and the Utah Battery, aggregating about thirty-five hundred men. The general health of the men is excellent, the sick report, exclusive of cases that were placed in the hospital immediately after arrival, being 4.6 per cent. of the effective force, and made up of trivial ailments, the fears that were entertained of serious illness, owing to the scanty clad condition of the men, have not been realized. The interior police of the camp of the Second Oregon Volunteers is not good; kitchens, dining rooms, bath houses, and lavatories are not kept tidy and clean, in spite of orders reiterated each day by the colonel of the regiment. The contrast between the work of the scavengers with that of the soldier police is very marked and fully sustains the opinion previously expressed in my reports, that the untrained soldier can not be made to do the work of a scavenger, to which I must add, nor can he be made to keep himself or his surroundings clean.

The food supply is abundant, well prepared, cooked, and served. There is added to each one hundred of the regular rations twelve gallons and a half of milk, ten pounds of butter, and ten dozen eggs. It may truthfully be said that the food in this camp is much better in variety, quality, and preparation than is found in the average hotel anywhere in this country." The report states that the detention camp on Angel Island is so far completed that it can accommodate one regiment. The camp for recruits is occupied by about four thousand men. Colonel Greenleaf adds, "Boards of medical officers are in session for examination of the physical condition of the men who arrive, and many have been rejected; the exact percentage I have not been able to ascertain, but it is large enough to show that sufficient care is not yet exercised in the selection of recruits, especially for service in the tropics. In order that errors in diagnosis may be avoided medical officers are instructed to make careful study of all fever cases. The food of the recruits is ample in quantity, but has little variety beyond the regular ration; it is fairly well cooked but indifferently served. There is great difference in the cleanliness of this and the volunteer camps; the police work of the recruits under direction of regular officers is well and thoroughly done."

As to transports, he remarks: "All transports while in dock preparing for the voyage are carefully inspected by the medical superintendent, and immediately before sailing I also inspect them. In every instance they have been found in good condition."

Singular Diet for Man and Beast.—A physician lately fed a dog on the morning of an experiment; he afterward dined on the roof of the Waldorf-Astoria and in the evening ate indoors. Next!

Caution: an Office Thief.—We have received from a reputable physician in New York the following description of an office thief, and we publish it that our readers may be on their guard. The man is a mulatto, about twenty years of age. He brings a fictitious address, asking the physician to call there urgently. So soon as the physician has left, he returns and asks permission to be allowed to wait. His request being acceded to, he lays hands on anything he can and decamps. Should any physician succeed in trapping the thief in question our informant expresses his willingness to appear against him.

Leprosy in Germany.—According to the Temps, of Paris (cited in Progrès médical for August 5th), although leprosy has almost disappeared from the greater part of Germany, it is still so common in eastern Prussia that a leprosery has recently been established near Memel.
Original Communications.

FRACTURE OF THE LOWER END OF
THE RADIUS.*

By CARL BECK, M. D.,
NEW YORK.

When I was asked by our esteemed president to read a paper before this society I thought that I could hardly select a more popular subject than this much-disputed one. "How do you treat Colles's fracture?" is one of the questions most frequently asked of a surgeon. "Do you use long or short splints? Do you prefer the plaster-of-Paris dressing or splint, or are you fond of Dunreichler's, Roser's, Schede's, Braatz's, Gordon's, Kollicker's, Moore's, Carr's, Bond's, Middeldorpf's bilateral, or the old pistol splint of Nélaton? Are you in favor of immobilization or of early motion?"

Such are some of the questions that show that this lesion is regarded as of a constant type, uniformly characterized by the fracture of the bone about an inch above the articulation, and followed by a silver-fork-shaped deformity of the wrist.

This point of view is inadequate and erroneous. The anatomical aspects of the various forms of fracture of the lower end of the radius differ more than those of any other fracture; and it is self-evident that such variants are by no means indifferent in the treatment. For a simple fissure, for instance, and for a Y-shaped intra-articular fracture, different therapeutic means must necessarily be sought. Again, the varying relations to that near neighbor, the ulna, are of great practical importance.

In regard to this protean fracture, as in many other cases, the Röntgen rays disclose many errors. It can safely be maintained that in most cases skiagraphy has revealed conditions which were not expected and have required the original diagnosis to be more or less modified. It goes without saying that the treatment has had to be modified accordingly.

Since March, 1896, it has been my privilege, at the St. Mark's Hospital, the German Poliklinik, the West Side German Dispensary, and the Sheltering Guardian Orphan Asylum, to skiagraph all cases of fracture and suspected fracture. Among this abundant material fracture of the lower end of the radius has been found sixty-two times. That in a large number of cases fissure of the head of the ulna coexists, as reported by me first,† has been corroborated by Kahleyss.‡ Another surprising feature has been that simultaneous fracture of the styloid process of the ulna was present in the greater majority of cases, an event which was formerly supposed to be of extremely rare occurrence.

It is but natural that our views should be changed by fuller clinical experience and anatomical observation. Without undervaluing the great experience of our surgical masters before the Röntgen era, the rays furnish the most convincing proofs for the necessity of modifying their interpretations of this injury. Thus, dwelling upon old experience, as well as on information gained but recently, I have tried to classify those different forms of this much-disputed fracture which appear to be most characteristic, and accordingly demand different therapeutic measures; and if we bear in mind the fact that the fracture of the lower end of the radius is the most frequent fracture type (eighteen per cent. of all fractures), the importance of the subject will be evident at once.

* As is well known, fracture of the lower end of the radius is usually caused by a fall upon the hand while in dorsal extension. The very strong ligamentum carpi volare profundum being more resistant than the spongy end of the bone, it is easily understood why, as first demonstrated by Nélaton, it never breaks; so that only a fracture can be the result. Practice shows that true dislocation of the radius at its lower end is so rare that only a few surgeons ever see it during a lifetime.

In classifying the different varieties of this fracture it seems to me to be essential to distinguish epiphyseal separation, fissures (infractions), complete fractures, incomplete fractures, fractures of the lower end of the radius combined with infraction or fracture of the head of the ulna, and fractures of the lower end of the radius combined with fracture of the styloid process of the ulna. All these different varieties may be extra-articular as well as intra-articular.

* Read before the New York County Medical Association, April 17, 1899.
† The Röntgen Rays in Surgery. International Medical Magazine, May, 1897.
‡ Beitrag zur Kenntniss der Fracturen am unteren Ende des Radius. Deutsche Zeitschrift für Chirurgie, No. 12, November, 1897.
Epiphyseal separation of the lower end of the radius shows the same symptoms and has to be treated on the same principles as the complete fractures. In very young children there are real chondro-epiphyseal separations (Fig. 1), the epiphyseal cartilage being sharply severed from the osseous end of the diaphysis; while later, at the age of between fourteen and seventeen, osteo-epiphyseal separation is observed, the fracture line not being limited to the epiphyseal cartilage only, but extending to the diaphysis. The latter variety occurs more frequently than the first one, which is extremely rare. (See Fig. 2, right hand.)

Fissures (infractions) are extra-articular as well as intra-articular, and are far more frequent than had been supposed before the discovery of the Röntgen rays (Fig. 3). In former times fissure was doubtless treated as distortion or contusion. No displacement being present, it is easily understood why such injuries often healed under any treatment. Sometimes these cases, not being recognized in their true light, gave a better prognosis than those which were properly diagnosed, but in which the bones had been immobilized during too long a period, so that adhesions formed in the sheaths of the neighboring tendons; while without immobilization, the hand being constantly used, the formation of adhesions was prevented.

The line of infraction in these cases is either transverse, as in Fig. 3, or longitudinal, so that the bone appears as if divided into halves, or it is irregular in shape, generally resembling a star. Then the bone is divided into several, but still cohering, portions.

The signs are severe pain and slight swelling at the seat of infraction. Abnormal mobility, and in consequence crepitus, being absent, the diagnosis of contusion or distortion is obviously often made.

Treatment.—No displacement being present, no reduction is required. This explains why the results in these cases are nearly always good, no matter what treatment is employed. In fact, if they are treated by a quack, whose ignorance leads him to treat the injury as a sprain with an ointment, poultice, or "faith," a better result may be obtained than by the surgical neophyte who, after a most erudite diagnosis, immobilizes the joint for a long period in his zeal to keep the imaginary fragments together. Of course, no deformity will result, but adhesions are formed, and the wrist may become stiff and immobile. In such a case a patient who was not treated at all—in other words, whose hand was not immobilized—would escape serious consequences.

If the Röntgen rays prove the existence of a fissure beyond a doubt, a wire splint which is slightly bent downward is applied at the flexor side of the arm, where it reaches from the tips of the fingers to the elbow, the downward-bent portions of the splint being attached to the palm of the hand. If there is much swelling, the dressing must be kept moist with Burow's solution.

After three or four days, when the swelling has subsided, this long splint must be removed and a brace-
permits enough motion to counteract the formation of adhesions in the sheaths of the tendons. The patient carries his hand in a sling in such a manner that the ulnar margin rests on it. Thus free motion of the hand is permitted. The patient is told to move his fingers as in playing the piano. I also find it very useful to advise the patient to grasp marbles of moderate size and to roll them around in the palm of the hand. Patients generally like to keep them in their pockets and play with them while reading or conversing or walking around. If motion is thus kept up constantly, massage treatment, as well as forcible motion, can be dispensed with.

Complete fractures, the most frequent varieties of fracture of the lower end of the radius, must be divided into intra-articular and extra-articular.

The intra-articular variety is the most important, as it always presupposes more or less grave injuries to the joint surfaces. The line of fracture is generally oblique (Fig. 4), but sometimes nearly longitudinal. The tendency to displacement is particularly marked in this form. Still, abnormal mobility, and crepitus accordingly, are but seldom noticeable.

As there is generally a well-marked extravasation, which may extend even over the sheaths of the tendons, palpation is rendered extremely difficult and uncertain. Massage has to be employed first in order to remove the extravasation, when sometimes the margins of the severed fragments can be grasped. Another valuable sign of fracture, deformity, caused by the displacement, may also be veiled on account of the extravasation. It goes without saying that another sign of fracture, severe local pain, is never absent.

From a consideration of all these points it becomes evident that a detailed diagnosis of this type is only possible by the aid of the Röntgen rays, which show us also just how the displaced fragments are to be reduced. Sometimes reduction can only be done properly if an anesthetic is employed. Forcible extension for the purpose is contraindicated, because it would increase the traumatic synovitis which is always present in this variety. The severed fragments are readjusted best by gentle grasping manipulations. An adhesive-plaster pad is applied over the displaced fragment after reduction is accomplished, and moderate pressure used for a few days until slight agglutination can be expected. Otherwise the treatment is the same as that of the extra-articular variety (see below).

Among all the different types of fracture of the lower end of the radius the intra-articular is the most serious. Only the continuous control, by the aid of the Röntgen rays, of the proper situation of the fragments will give good results.

The extra-articular complete type is the best known among the varieties of this fracture. Having been first described by Colles, it is called Colles’s fracture in this country as well as in England. It is generally transverse, and so has the character of a supracondylar fracture. Its seat is about three quarters of an inch above the articulation, where the compact tissue of the diaphysis passes over into the cancellated spongiosa.

Signs.—Displacement always being present in this type, the deformity is most characteristic. In most cases the direction of the displacement is upward, so that there is a dorsal prominence. Then the shape of the deformed wrist resembles that of a bayonet or a fork, wherefore Colles’s fracture has also been called silver-fork fracture (displacement à la fourchette) (Fig. 5). By thus being upwardly dislodged, the epiphysial portion is brought into slight supination, while the diaphysis is in decided pronation. The epiphysis being in very close connection with the ulna, the latter is slightly pushed toward the ulna if the ligamentous connection between the radial fragment and the ulna remains intact. This phenomenon finds its conspicuous expression in the lateral prominence of the styloid process of the ulna.

Sometimes the tendency of epiphysial displacement is toward the opposite side or downward. Then the deformity appears accordingly. In the first case the direction of the displacement was never recognized in the pre-Röntgenian era.

Abnormal mobility is always present to a greater or lesser extent. Consequently there is always crepitus.

In examining the patient, a firm support must be obtained for the injured hand, the latter being kept down on a plane by an assistant and the epiphysial fragment being grasped. Inspection invariably detects the characteristic abnormal prominence, while palpation is
often able to outline the shape of the fragment. The local pain is generally severe.

In the rare event of impaction of the epiphyseal end into the upper end of the radius, abnormal mobility and crepitus are absent (Fig. 6).

(To be continued.)

A TEST CASE FOR TASTE.
By NATHAN T. BEERS, Jr., M.D.
BROOKLYN.

The value to the physician of any method of examination depends not only on its theoretical correctness, but quite as much upon the ease and exactness with which it can be applied clinically.

The little test case here described presents nothing radically novel, something of the kind having been described by Goldscheider; but from its neatness, compactness, and perfection of detail it is believed that the apparatus may prove convenient and useful.

The general make-up and adaptability of the case are shown by the accompanying illustration. When filled for use, the whole weighs only thirteen ounces. The containing box is made of light mahogany, so dovetailed together and highly polished as to be durable and likewise pleasing to the eye. The four small half-ounce phials containing the test solutions are fitted with ground-glass pipette stoppers of the flat-top variety, thus making it more compendious and giving greater delicacy in dropping. The bottles are steadied for transport by polished spring clips. In the small hollow at the bottom of each bottle is pasted the name of the solution, in this way keeping the information from the person examined.

One object of the arrangement of this case is to keep the solutions free from contamination. This serves a double purpose, as hereby not only will the solutions remain much longer free from decomposition, but also we are spared any chance of carrying over infection.

This apparatus serves for the qualitative, regional, and approximately the quantitative determination of the sense of taste.*

For simple qualitative tests the mouth may be closed and the solution "smacked," but in regional and quantitative tests the tongue must remain exposed and not touched to the surrounding parts. In making regional tests the printed card which is fastened to the front of the box (and covered with transparent cellloid to prevent staining) becomes necessary. The person examined is directed to protrude the tongue while the drop is carefully applied to one or another part of the tongue, and he then can indicate which taste is appreciated by pointing on the card. Failure to detect any taste whatsoever may be indicated by a shake of the head or hand.

Quantitative measurement is here meant to indicate the exact determination of the degree of taste impairment. This is accomplished by varying the strength of the solutions through equal dilutions.

While it is not strictly the purpose of this paper to

---

* These terms, as here applied in examination of the senses, are suggested by Dr. William Browning, at whose instigation the case was devised.
more than describe the apparatus, it may not be amiss to offer a few suggestions on the preferable solutions and methods.

Of course, only colorless solutions are admissible. In the test solution the volatile hydrochloric acid may well be replaced by phosphoric acid, and because of less tendency to fermentation and change saccharin is preferable to sugar.

It is only the anterior two thirds of the tongue (border and tip, supplied by the chorda tympani) that we usually care to examine. If it were desired to test the faucial pillars and pharyngeal walls, the person might first be directed to assume the reclining position.

Solutions of the following strengths are suitable for general use. The practitioner, of course, may vary or change them to suit his own fancy without detracting from the value of the case:

**Bitter.**—Quinine sulphate, a quarter of a grain to an ounce of distilled water (about 0.65 per cent.).

**Sweet.**—Saccharin, one tenth of a grain to an ounce of distilled water (about 0.62 per cent.).

**Sour.**—Phosphoric acid (pure), three minims to an ounce of distilled water (about 0.66 per cent.).

**Salty.**—Sodium chloride, five grains to an ounce of distilled water (about one per cent.).

1265 Bedford Ave.

ADENO-CARCINOMA OF THE NOSE.

REPORT OF A CASE.*

By JAMES E. NEWCOMB, M.D.,
ATTENDING LARYNGOLOGIST TO DEMIT DISPENSARY
AND TO THE ROOSEVELT HOSPITAL, OUT-PATIENT DEPARTMENT;
INSTRUCTOR IN LARYNGOLOGY IN CORNELL UNIVERSITY MEDICAL COLLEGE.

Two years ago, at the congress of this association held in Washington, cases of this nature were reported by Dr. Hopkins and Dr. Leland. Appended to the paper of the former, as published in the *Transactions*, are some pertinent remarks by Dr. Wright on the general topic of nasal carcinoma. Dr. Hopkins was able to collect up to the date of his paper the authentic records of twenty-three cases of the different varieties of this form and site of new growth. Of this number, three were undoubtedly adenocarcinoma and one other doubtfully so. From the conviction that all such cases should be placed on record, I am influenced to report briefly an additional case, and to add a few words on two matters relevant to the subject—viz., cases reported during the last two years, and a modification of one of the surgical measures followed in these cases which has commended itself to my judgment.

Mrs. Caroline C., aged sixty-one years, widow, of American parentage, was referred to me by my friend and neighbor, Dr. William C. Gardner, January, 1889, on account of severe and persistent nosebleed. Her family history was negative, and her previous history was without apparent bearing on her condition when seen. In June, 1898, she began to have almost daily bleeding from the left naris. She had been subject for many years to severe colds in the head, and was inclined to attribute her troublesome symptom in some way to this fact. The bleeding always stopped of its own accord, and no operative interference had ever been necessary. On two occasions the flow had been quite severe, but on all others it had been a mere dribbling. In September she had blown from the nose what she described as a “fleshy bean,” which was in all probability a polyp of the usual variety. She had lost some flesh and strength during the few preceding months, but no more than could be accounted for by the continual though slight bleeding. At times there had been a slight watery discharge with an offensive odor. None was present at the time of examination.

The latter showed a woman of large frame, but with a rather worn and debilitated appearance. Pharynx, nasopharynx, and larynx presented nothing especially noteworthy. The right naris showed commencing senile changes. The left was considerably occluded. The middle turbinate was considerably enlarged, and the mucous covering it appeared to be in a condition of polypoid degeneration. About it were two or three fleshy proliferations, which bled rather easily upon manipulation with the probe. No glandular enlargement could be found and there were no manifestations of pressure symptoms.

Under ten per cent. cocaine a portion of one of the fleshy masses was removed and sent to Dr. Wright for examination. His report was “adenocarcinoma.” Removal was followed by a little more bleeding than is the case with an ordinary polyp, but it was easily checked, and there was no unpleasant reaction.

The patient was seen again in two or three weeks, when it was noticed that the mass had reproduced itself in the same situation. A second piece was removed as before. There had been no bleeding in the interim. The report upon the second piece was to the effect that it consisted of edematous tissue with some newly formed and imperfect glandular structure—all of it granular and degenerate-looking—nothing definitely malignant, but certainly suspicious. Patient was seen again for the third time on March 13th of the present year. The same redundant growth of tissue was noted as before, but none was removed at this time. There had been two spontaneous hemorrhages during the week preceding this visit, one of them quite severe. The patient was made acquainted with the gravity of the situation, and the question of a radical operation was submitted fairly to her. Thus far she has been unwilling to undergo the ordeal.

She was last seen early in the present month (May, 1899). During the last few weeks the daily dribbling hemorrhages have continued, and at times there has been a perceptibly offensive odor. The occlusion of the nostril is gradually increasing. Her general condition seems to be about as before.

I have made a careful search through current literature issued between the date of Dr. Hopkins’s paper and the 1st of March of the present year and have been able to find records of the following cases;

* Read before the American Laryngological Association at its twenty-first annual congress.
Schotte reports the case of a woman, aged forty-five years, who presented a growth of the left inferior turbinate with polyps of the middle turbinate on the same side; removal; microscopic diagnosis, "papillary epitheliuma." This form of neoplasm is now regarded as closely allied to adenoma, and has been called by Billroth Zottenkrebs. A specimen is figured by Dr. Wright in the American Text-book of Diseases of the Eye, Ear, Nose, and Throat, and some remarks made upon this form of growth.

Thorner, of Cincinnati, reports a case in a man of forty-seven years. The tumor grew from the left middle meatus. Dr. Thorner notes that most authorities regard pure adenoma of the nose as among the rarities. Simple polyps sometimes undergo malignant degeneration, and malignant growths may lurk behind simple polyp. Hence the stage at which the case comes under observation must be considered in any attempt to unravel the problem in each individual. Newman has quoted the opinion that two thirds of carcinomatous tumors of the nose are epitheliumatosus, and the remaining third adenomatosus. But from any histological point of view it must be remembered that the exact demands of modern diagnosis render earlier statistics very unreliable.

Thorner also reminds us that while we may not be able to positively deny the transformation of a primary benign tumor, a pure adenoma, into a malignant growth—adeno-carcinoma—it must be remembered that there are certain forms of adenoma which are malignant from the beginning, and should be termed "adenomata maligna," although it may well be that for a long period they can not be distinguished in anatomical details from the benign variety. Some tumors, originally innocent in type, pursue a course of extreme malignancy, and in a certain percentage of cases microscopic examination is unable to determine whether a given growth will prove innocent or malignant in its development.

Saitta mentions a case of adenoma of the left nasal fossa, the exact site of which could not be determined. It occurred in a woman of sixty years. The later history of the case was not obtainable. Microscopic examination led to a diagnosis of adenoma with inipient carcinomatous metamorphosis.

Tissier, in the course of an elaborate article upon Tumors of the Nasal Passages, notes that cancer of the nose is very rare. He quotes the statistics of Gurtit to the effect that only four cases were found out of a total of nine thousand five hundred and fifty-four cases of cancer of all organs. He can not see in an antecedent rhinitis anything more than a coincidence. Erysipelas and tumors have both been invoked as exciting causes. There is nothing, he says, but mere coincidence between the association of polyps with the malignant growth. He does not regard the epitheliumatosus transformation of simple polyps as ever having been definitely proved. But he adds that what we know about the atiologie of nasal polyps explains their occurrence in a cancerous nasal fossa. He believes the ethmoidal labyrinth to be the most frequent seat of carcinomia, a fact which tends to explain its most frequent extension toward the orbit and cranial cavity. Next in frequency as to site comes the septum. Ganglionic infection is rare and relatively tardy. The average duration is not more than one year in cases of non-interference, but it may extend to four years. He gives quite a full bibliography, but apparently does not include any cases which are not mentioned in the table appended to Dr. Hopkins's paper.

Hellman narrates a case which is of interest as illustrating the transformation of a hard papilloma into carcinomia. His patient (male) had been observed as far back as 1886, being at that time thirty-seven years old. The mucosa over the left middle turbinate was thickened, of yellowish-white appearance, and covered with fine maumilations. The intervening areas were apparently healthy. No enlarged glands or adhesions were present, but the growth completely occluded the nares. Removal by galvanoeauty was followed by quick recurrence. For the next nine years he was under the care of various physicians and had an annual crop of polyps removed. At the end of this time Scheel removed a mass of fine papillary growths, suspecting cancer, but no examination was made. In July, 1895, Scifert removed some of the growth, which he pronounced to be hard papilloma. Two months later further masses were removed by Hellman and found to be true carcinomia.

Bronner reports a case of tubular epitheliuma removed from the nasal mucosa of the lower turbinate in a man of forty-seven years. There was a history of slight nasal obstruction and frequent hemorrhages. Removal was effected by scissors, and the base cauterized with the galvanoeauty. Microscopic examination showed that the growth was malignant and of an epithelial type. At the periphery, beneath the mucosa, tubules with a definite lumen could be seen. There is some doubt as to whether this tumor was anything more than an adenoma. There had been no recurrence after ten years.

Martuscelli alludes to a case of tumor of the cartilaginous septum supposed to be a fibroma or chondrofibroma, but examination showed it to present some features of epithelioma and some of lupus. A perusal of his report does not persuade the reader that the case belongs in the category now under consideration.
In a recent number of the British Medical Journal, Hunter MacKenzie, in reporting a case of sarcomatous degeneration of a nasal polyp, brings up the question of surgical trauma inflicted in the removal of polyps as a possible factor in causing such malignant degeneration. Plicque is on record as stating that "it must be remembered that it is, unhappily, pretty frequent after ablation of numerous benign polypi—adenoma or myxoma—to find new polypi appearing, composed this time of epitheliomatous tissue." While these notes of warning are not to pass unheeded, it can not be believed that the propositions they advance, especially the latter of the two, are true, except in a very small proportion of cases. Otherwise, considering the great number of cases of nasal polypi and the crude methods often employed in the removal of the latter, nasal tumors presenting malignancy would be much more frequent than is actually the case.

With the case reported in this paper there are thus five new cases to be added to those enumerated in Dr. Hopkins's table.

In regard to the surgical measures for radical interference, I beg to add a word. Up to the present time two general operative plans have been followed: First, removal of the superior maxilla with more or less of the surrounding structures, and, second, attempted starvation of the growth by shutting off its blood supply. In pursuance of the latter end the external carotid has been ligated. I have been interested to learn of a modification of this procedure, first made, I believe, by Dr. R. H. M. Dawbarn, a well-known surgeon and expert anatomist of New York. He found, upon studying the anastomotic circulation, that after simple ligation of the external carotid there were fully twenty channels through which collateral circulation could be established. With a view, therefore, of still further cutting off the blood supply, he conceived the idea of ligation, one after another, the eight branches of the external carotid, and then, as the trunk of the vessel was thus rendered useless, of resecting it entire. He has done this operation sixteen times upon eight patients, a two-weeks' interval elapsing between the two operations in each case. It has been done once or twice by others. While the period covered by this work is too short and the number of cases thus operated upon too few to allow of decisive conclusions, he believes that time will demonstrate the logic and effectiveness of this operative modification.

**TRAUMATIC NEUROPSYCHOSIS.**

**REPORT OF A CASE.**

By C. E. IDE, M. D.,

CHICAGO.

On May 11, 1896, T. O., native of A., New York, aged fifty-one years, a farmer, married, was sent to me by his lawyer for examination. On inquiry I elicited the following: Family history good. In infancy he had measles, scarlatina, variola, pertussis, and chicken-pox. After this he was always perfectly well, being a large, powerful man, non-alcoholic, nor could I find any signs of syphilis. He denied having had either syphilis or gonorrhea.

On October 27, 1895, Q. was driving eastward to his home from M., where he had been to make purchases. When about three miles from home, as he was driving over a bridge which spanned a culvert, his horses shied at some timbers which were piled on the south side of the road, on the east side of the culvert. The horses, wagon, and occupant were thrown into the culvert on the north side of the bridge. The bed of the culvert was dry and filled with rocks. Q. stated that he was unconscious after the fall, "came to," and started east, locomotion being exceedingly difficult. On reaching the first house, that of a friend, he shouted for assistance. Friends came out, took him in, and sent for his physician.

He stated that he suffered, after recovering from the unconsciousness, from pains all over his body and general tremor. After being seen by his physician he walked, with assistance, to his friend's buggy, and was taken home and put to bed. His whole body was cold when he arrived home, indicating a state of shock. It hurt his back so to pull off his boots that they had to be cut off.

He was in bed about a week, and during this week the following symptoms manifested themselves:

1. Cerebral: Dull occipital headache, insomnia, sensation of a band about the head, sensitiveness of scalp.

2. Mental: Morbid fears of seeing people, despondency.

3. Spinal: Pain in back and arms and down through the abdomen; tremor of hands and arms. The tremor is really a cerebral symptom, cerebral inhibitory power over the spinal reflex centres being lost.

4. Gastro-intestinal: Passage of blood and mucus from the bowels.

5. Sensory and motor: Dysphagia, imperfect vision, tinnitus.

After getting up from bed there were: 1. Cerebral: Dull, occipital headache continued, insomnia continued, vertigo, sensation of a band about the head continued, and sensitiveness of scalp over occiput continued.

2. Mental: Dislike of seeing people continued, dislike of solitude (wanted his wife with him all the time), despondency continued, easily excited, change of character shown by irritability of temper (his wife said that this was something new for him), forgetfulness, a feeling of oppression over chest with dyspnea and melancholic facies.

3. Spinal: Back sore, lame, and painful; some paresis of legs (he said his legs were weak, stiff, and heavy); some paresis of bladder (he said he micturated frequently, but that the "water passed slowly"); slow and feeble movements, marked hyperesthesia of skin of back, retarded conduction (no complete anesthesia), impaired sexual power, tremor of hands and arms, no ankle clonus, knee-jerk somewhat increased.

4. Vasomotor: Cold extremities, undue sweating, blue-ness of hands and feet, cardiac irritability (tachycardia), palpitation.

5. Gastro-intestinal: Constipation, anorexia, indigestion (furred tongue, foul breath), eructation of gas, pain in bowels, distention of abdomen with gas, epigastric pain.
6. Sensory and motor: Tinnitus, imperfect vision, dysphagia, photophobia, hearing overacute, concentric limitation of the visual fields (pupils reacted), concentrically injected, motor asthenopia, sensitiveness of eyeballs, sense of touch and perception of heat and cold much impaired—conduction slow in all (instead of complete analgesia the prick of a needle was perceived very tardily and faintly), grip was weakened, muscular sense tardy, slow and labored gait (walked with a cane).

I am sorry to say that the electrical reactions could not be tested when I examined the man. He lost flesh and strength rapidly, and at the end of a year showed no inclination or capacity for work. Previously he had been a hard-working farmer. The urine was concentrated, high colored, showed an abundance of urates, no albumin or casts. I felt that pure malingering could be excluded. I did not perceive any simulation. Q. is the sort of man who has never read much, and had not thought much of medical matters, as some men do. In fact, he is an ignorant Irishman.

As for exaggeration, another resident of the same vicinity had been injured in a railroad accident a year before and had received heavy damages. This fact, I think, led Q. to desire to make every symptom count for all it was worth; but I feel sure that he was not intelligent enough to simulate any symptoms. The objective symptoms I looked for, and found those reported, without the asking of any unnecessary questions. He was observed again later, the same symptoms persisting.

At the end of seven months from the accident he was able to get into his wagon and drive to other villages. On one of these occasions the front of his wagon body gave way and he slipped down behind his horse. Bilateral inguinal hernia resulted from this, and when I examined him he told me that this resulted from his other accident. This attempt to deceive me and his tendency to exaggeration of symptoms covers this aspect of the case.

This I believe to be a true case of traumatic neuro-psychosis. In the spring of 1897 Q.'s case came up in court and he lost, mainly, I believe, because he was foolish enough to swear falsely that his hernias resulted from his first accident. Our knowledge of the medico-legal aspect of these cases will readily allow us to see how this would influence the average jury against him. He had a good case, but ruined it by lying in the hope of gaining greater remuneration.

SYNECHIOTOMY OF THE STAPES
FOR IMPROVING THE HEARING IN CHRONIC SUPPURATIVE OITIS MEDIA RESIDUA.*

By EDWARD BRADFORD DENCH, M.D.,
PROFESSOR OF OTOLARYNGOLOGY
IN THE UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE;
AUDITORY SURGEON TO THE NEW YORK EYE AND EAR INFIRMARY;
CONSULTING OTOLARYNGOLOGIST TO ST. LUCY'S HOSPITAL;
CONSULTING OTOLARYNGOLOGIST TO THE NEW YORK OROTONOLOGIC DISPENSARY AND HOSPITAL.

A certain number of cases come under the observation of every otologist in which a purulent inflammation of the middle ear has either undergone spontaneous cure, or where the discharge has ceased, as the result of operative interference. In a large number of these cases, however, the hearing is noticeably impaired. It is not infrequently found that in cases of long standing the patient complains of a steady deterioration in audition in the opposite ear. An examination of this organ often shows but slight evidence of middle-ear inflammation where there are decided signs of beginning labyrinthine involvement. The aural surgeon has then to deal not only with the ear which was first discussed, but with that which has become secondarily involved. My own experience has taught me that operative interference upon one side is followed by extremely beneficial results upon the opposite ear.

By the term synechotomy I mean the division of adhesions about the stapes. Those most usually lie between the posterior crus of the osseous and corresponding wall of the oval niche; the next most frequent location is between the crura and inferior wall of the niche. Occasionally they are found superiorly and anteriorly. The operative technique is comparatively simple. The procedure can easily be conducted under cocaine anesthesia, or, if this is found to produce unpleasant constitutional effects, a solution of eucaine (b) may be used. As this latter drug causes a hyperemia of the tissues, its application should be followed by that of a sterilized solution of suprarenal extract. This latter application will sufficiencies control the engorgement caused by the eucaine to assure the operator a clear view of the field of operation. Prior to any operative procedure of this character the parts should be sterilized by thoroughly mopping out the canal and tympanum with an alcoholic solution of bichloride of mercury, of a strength of 1 to 3,000. After the field of operation has been properly prepared, the first step is to divide any adhesions which may lie between the posterior crus of the stapes and the adjacent wall of the oval niche. If a fragment of the drum membrane remains and prevents a clear view of the stapes, it is better to excise this as a primary procedure. In certain cases, owing to the position of the stapes, the ossicle can not be seen. This is particularly true where posterior adhesions are present, the ossicle being drawn backward behind the tympanic ring. Knowing the normal position of the stapes, it is a comparatively simple matter, after local anesthesia has been thoroughly established, to divide these adhesions, although the ossicle itself may be completely hidden from view. In order to do this a sharp-pointed knife is introduced into the middle ear in the upper and posterior quadrant, close to the tympanic ring. The knife is carried inward until the bony wall of the tympanum is encountered. It is then swept downward, the point being still kept in contact with the internal tympanic wall. In this way all adhesions lying between the posterior crus of the stapes and the adjacent wall of the oval niche are divided, including the tendon.
of the stapedius muscle. Not infrequently, where the stapes is invisible before the procedure, it is easily seen after the incision has been made, owing to the division of the adhesions which have drawn the ossicle upward and backward. The operation itself, if carefully conducted, is absolutely painless.

Prior to the operation a careful functional examination should be made, and this should be repeated after each successive step, so as to note the effect upon the lower tone limit and upon the power of audition. It is not uncommon to find a marked improvement in hearing after a simple division of posterior adhesions. If this does not follow, the operator should next pass the knife beneath the crura of the stapes and the adjacent wall of the niche. Careful mobilization of the ossicle by means of the cotton-tipped probe is also advisable, both the hearing and the lower tone limit being tested from time to time to see what improvement follows the procedure.

My own records show twenty-six cases in which operation was done in this manner. Of these, improvement was shown in twenty-five, while in one case no improvement followed the operation.

The after-treatment is exceedingly simple. If the field of operation has been properly sterilized, it is only necessary to occlude the meatus with a pledget of sterilized cotton. This should be changed daily, and at the same time the meatus wiped out with a pledget of sterilized cotton. Frequently there may be a serosanguineous discharge from the ear for from three to four days after the operation; at the end of this time the tympanum becomes dry. I usually direct the patient to keep the meatus occluded while in the open air for at least ten days after the procedure. At the end of four or five days, if there is no discharge, the ear may be left open while the patient is in the house, a cotton pledget being inserted when the patient is in the open air or in a dusty place.

In many instances the effect upon the opposite ear has been exceedingly marked; not only does the hearing improve, but the subjective noises are often relieved, and a beginning inflammation of either the labyrinth or the middle ear is effectually curtailed.

BOVINE TUBERCULOSIS
IN ITS RELATION TO MAN.
By EDWARD MOORE, M. R. C. V. S.,
ALBANY.
(Concluded from page 338.)

Transmission from Human to Bovine.—It is of less interest to physicians whether tuberculosis is transmitted from the human to the bovine; still, if the disease is intercommunicable, as we are assured it is, then it is equally important either way. I have not been able to learn of a case where the disease was established in a cow or a herd from human sputum. Dr. Cooper Curtice says: "In 1897 I tested two hundred and forty cattle in the vicinity of Saranac Lake, New York. Every one there supposed that I would find tuberculosis in herds that fed in the fields where the consumptive patients that resort to this place take their exercise. Not one case was found. Not only this, but the herd of the sanitarium had been previously tested with like results. If tuberculosis could be transferred to cattle from human beings, it should certainly occur at such a place as Saranac Lake, a sanitarium where thousands of consumptives resort. Thus, while feeding experiments may have been interpreted as showing in some instances that infection from human to bovine was possible, it seems very well established that the infection from man to cattle does not obtain when consumptive people and healthy animals occupy positions toward each other daily which are calculated to offer every opportunity for such transmission. Dr. Theobald Smith is certainly working in the right direction; his article, A Comparative Study of Bovine Tubere Bacilli and of Human Bacilli from Sputum, is based upon scientific investigation of a very high order, and his deductions go a long way toward the establishment of the principles promulgated in this paper. He says: "The absolute identity of tubercle bacilli infecting mammalia has been so generally assumed, and the assumption used as a basis for the enactment of sanitary measures having for their object the prevention of any transmission of tubercle bacilli from animal to man, that any one who would attempt to question this identity must be prepared to meet considerable skepticism. Taking a broad biological position, we have every reason to examine into the assumed identity of the bovine and the human bacillus." Exactly, and we shall facilitate this important work in proportion as we cease to be parrots in repeating what we have been told, and as we rise above mere assumption, and sean closely every bit of evidence, giving credence to nothing that is not warranted by scientific investigation, indefatigably pursued, to the end that truth may be established. Dr. Smith has demonstrated that human bacilli grow more vigorously from the start than do those from the bovine; that the length of the human bacillus is about two to three times that of the bovine, in cultures; also other morphological and biological characters in which they differ. More convincing are the divergencies in their physiological effects, as shown by his experiments, in which there was more rapid death of all guinean-pigs inoculated with bovine bacilli than those inoculated from human sputum. Experiments on rabbits confirmed those of the guinean-pigs. His experiments on cattle by the inoculation of bovine tubercle bacilli and human bacilli in some ten cases show "slight local lesions at the point where the syringe was inserted when human sputum bacilli were used, the disease not spreading. When the bovine bacilli were introduced there was disseminated tuberculosis of the-
lungs, tubercular deposits in lungs, ribs, pericardium, and diaphragm, extensive tuberculosis of nearly all the lymph glands of the thorax, and slight tuberculosis of the spleen, liver, and kidneys." These differences are so great that comment is unnecessary. Dr. Smith summarizes them in the following language: "The foregoing experiments, while they show unmistakably the close relationship existing among the various cultures studied, nevertheless justify us, if only to guide and stimulate further study, in establishing a distinctively human, or sputum, and a bovine variety of the tubercle bacillus." These modern experiments are infinitely more reliable than those so often quoted of earlier investigators, because our knowledge is greater, our facilities are better. I will presently offer some practical evidence from the everyday lives of people who are constantly exposed to the infection from bovine tuberculosis. I know the cattle, know the percentage of diseased animals in the herds, and have been aware of the existence of disease in the herds for from several to eighteen years. I have visited the people, dined with them when there were plenty of bovine bacilli on the table to satisfy any ordinary craving, and I have noted the health of those families, especially that of the children, many of them having all their lives used the products of herds largely infected, and I have not yet discovered a single case of human consumption therefrom. It is axiomatic that if transmission is common, or even possible, the farms where large numbers of infected cattle are kept are the places where the fact can be best observed; because nowhere else in the world is there so much infective material, nowhere else are the bacilli so potent, nowhere else are people so exposed to the danger, if any exists, and at these places feeding and inhalation experiments, so to speak, are constantly going on; and you will bear in mind that it is the mature cow that is most often affected, and it is from her that the largest amounts of milk, butter, etc., are used. A vast amount of work has been done by scientists to demonstrate whether milk from tuberculosis cows whose udders were not diseased contained bacilli, and it may be conceded that it does in some cases; they are also present in milk frequently when such milk is obtained from tuberculosis udders. Sternberg, in his Manual of Bacteriology, says: "A more common mode of infection, especially in children, is probably by way of the intestinal glands from the ingestion of milk from tuberculous cows. That infection may occur by way of the intestine has been proved by experiments upon rabbits, which developed tuberculosis when fed upon tuberculous sputum." This is the sill in the doorway of investigation over which many a bright man has fallen. It is assumed that the infant will do exactly that which rabbits and guinea-pigs have done. All the evidence I have thus far collected indicates that it does nothing of the kind. Physicians, as a rule, are not familiar with the conditions surrounding a tuberculous herd, hence I have deemed it necessary to show you one in imagination that you may the better understand the facts.

Tuberculous Herd at Home.—Picture in your mind two hundred cattle in elegant buildings of the immense size necessary to house such a family—electric light, proper ventilation, pure water, mountain air, drainage and plumbing up to date, strictest cleanliness, the best food stuffs given in balanced rations, pure-bred animals, everything first class, and all under the keen observation of experts who note details and record them—yet somewhere in the past a number of tuberculous animals were bought and added to the herd. Those diseased animals looked all right, else they would not have been purchased at high prices. And after a few years we find that twenty-five to fifty per cent. of the herd is tuberculous. Remember that cattle stand in rows in many cases. The manger is a continuous trough. The partitions between animals are low, and the cattle can reach each other on either side. They can cough up and blow sputum to a considerable distance, where it may fall on cattle to be licked off, or on food, or in water, or in feed troughs. The animals are turned out for exercise or pasture, drink at one trough, lick themselves and each other, and drool upon litter or herbage that others eat. When confined in the stable during winter, think how the dry sputum is converted into dust and wafted about by the breath blown from the animals, by their getting up, lying down, shifting feet, switching tails, the opening and shutting of doors, the sweeping, the general stirring up at the time of foddering, and you will realize that there is a series of motions night and day always operating to favor dissemination of the disease by ingestion, inhalation, and direct contact with mucous membranes. Suppose that we say of two hundred animals eighty are tuberculous; in this number are some with disease so located as not to be harmful to others, but many are diseased in organs which allow free exit to the infectious material. The attendants breathe this germ-laden atmosphere, they handle the cattle, and no doubt often convey to their nostrils and mouths sputum from the cattle. They and their families, and the proprietors and their families drink the milk, eat the cream, butter, and cheese, if the latter is made, and in some cases, though not often, they eat the flesh of calves or older animals. Here, then, is the greatest abundance of infective material—inhalation of germs before breakfast; at breakfast they are spread over the oatmeal, poured into the coffee, on the fruit, spread on the bread, taken in the glass of milk. All day the air is rich with germs, and they are served at every meal without extra charge, all furnished by the sanitary dairy company, unlimited, from the palace bovine home. Children often go into these barns, and are likewise exposed. What chances are there in cities for people to obtain infection from cattle, as compared to those just pictured in the country? Even the milk is most infective when freshly drawn.
from the cow, so far as bovine tuberculosis is concerned; the only way it can be more dangerous to people when served in cities and towns is through its contamination by bacilli from human consumptives. Yet your health laws all aim to protect the citizen; no one has ever suggested a law to protect farmers from infection by bovine tuberculosis. Again, the percentage of deaths from consumption is much higher in cities than in the country or in country towns. I recently wrote to some owners of herds where bovine tuberculosis has been long established and in which the percentage of diseased animals was high, and I quote the replies, omitting the addresses in some, but offer in evidence the original letters, which I trust you will inspect. In none of these places was milk sterilized, or any precaution taken to avoid infection. The butter that won the gold medal at the last Paris exposition was the product of a herd largely tuberculous. Thus we are again reminded that "all is not gold that glitters." A part of the seintillation may have been due to bacilli in this case.

The following extract is from a lady who has suffered extensive loss. Prior to the visit of the inspectors of the State board of health the farm and its herd of cattle were unequalled throughout the State.

**Dr. Edward Moore, Albany, New York:**

April 4, 1899.

Dear Sir: Your favor of March 6th received, and beg you will excuse my neglect in not replying sooner, but pressure of other matters crowded it out. In my opinion the actions of the State board of health were not only absolutely unnecessary, but absolutely criminal, and had I been in a position where I could, I fear I should have talked in Albany until some one was tired. My herd numbered nearly two hundred head, young stock and all, and they butchered over a hundred cows, leaving me with a herd of young stock on my hands. Some cows, after slaughter, could not be found to have even a pinhead size of a germ, even upon microscopic examination, while with the majority, if they could find a germ as large as a pea that might be called a tuberculous germ, the men in charge were happy. At the time the State seized the cattle the creamery was full of butter, which was quarantined and a sample of each package sent to Albany and tested. After all the stock was killed we received a clean bill of health upon the butter. There were absolutely no foreign germs or anything detrimental in it. But what of that? For the sake of giving a few cranks a job for a while, $30,000 worth of stock was killed. The blow killed my farm, and I have never been able to pull together since. I have never known a case of human tuberculosis to arise from the use of milk from my herd, either directly or indirectly. Our cattle had better care than thousands of children, and a regular veterinary three times a week, and a consulting veterinary twice a month always, and as often as needed at other times. I will send you under sepa-

rate cover a souvenir of the farm as it was. Trusting you may be able to allay such useless slaughter,

I am very truly yours.

The above one hundred diseased cattle appear to have utterly failed to transmit tuberculosis to the people surrounding them or using their products.

**Hotel Bristol, Naples, Italy, March 24, 1899.**

Dr. Edward Moore, Albany, New York:

Dear Sir: In reply to your favor of the 4th inst., I am always pleased to be of any service to you or any of my old friends.

In my twenty-five years’ experience with cattle I have never known any one who has had the care of cattle to have been infected with tuberculosis or consumption.

You are at liberty to use my name if you wish.

Very truly yours,

John Mayer.

The above letter is from a son-in-law of Mr. Have-meyer, and these two gentlemen had one of the largest and best pure-bred herds of cattle in the world, and their herd suffered extensively from tuberculosis for years. Mr. Mayer has traveled across the ocean several times for the purpose of examining the best cattle abroad and purchasing the best animals he could obtain. He made special investigation as to the freedom of various breeds from tuberculosis, and imported a lot of Swiss and Simmenthal cattle because he believed they would resist the disease better than the animals then composing their herd.

**Massachusetts Agricultural College, Veterinary Department, Amherst, Mass., March 7, 1899.**

Dr. Edward Moore, Albany, New York:

Dear Sir: Your inquiry to the director of the station regarding tuberculosis has been sent to me to answer.

In so far as I know, no one has ever contracted tuberculosis from contact with the animals in our old herd, or from the use of the milk or meat from the same. The records of our students and graduates only show a very small mortality from consumption. These records are not to be relied upon to prove that any student ever contracted the disease from the use of milk from the college herd, for they have not always had it for use. Some years the boarding club, which is run by the students and not by the college management, gets its milk from the farmers in town. I send you under separate cover a bulletin giving the history of our old herd.

Very truly yours,

James B. Paige, D. V. S.

The following letter is from a very prominent firm in another State who have maintained one of the largest herds in this country for many years. I have known that there was a good deal of tuberculosis in the cattle for sixteen years, and frequently in that time I have been at their farm and partaken of three meals a day.
for several days at a time. Two years ago the State veterinarian said that tuberculosis in cattle was a recent introduction into that State, yet the writer had killed many tuberculous cattle in said State before that man had graduated, or knew anything about the disease:

March 2, 1899.

My Dear Dr. Moore: I am in receipt of your favor, contents of which I carefully note. In reply I am glad to be able to say that our herd of Jerseys is in fine condition and doing most excellent work. Never better. We, by which I mean all our several families, have used the milk always from the herd very freely, and in every appearance we are, each and all, as hearty and robust as aborigines. In fact, I think we could discount them. I mean, of course, in general health and condition, not in the use of the tomahawk and scalping knife. We have employees who have been with us for years and constantly with the stock and about the stables, and never have we had a case approaching even a semblance of tuberculosis among them. Some of our men, one of them constantly employed in the stables, who have young children, have always used the milk, and I have never heard of any ill effects therefrom. In fact, judging from their activity and lung power, I should say they were remarkably robust and energetic. By the way, I do not hear so much about cattle commissions in this locality as I did once upon a time. But I recognize, of course, the necessity of being watchful in every way; yet I believe there may be great and unnecessary loss in hasty and ill-advised action. I have used the term "milk" in this letter, and I mean by this terms to include the entire dairy product, butter and cream. Very truly yours.

NEW JERSEY AGRICULTURAL EXPERIMENT STATION,
NEW BRUNSWICK, N. J., March 2, 1899.

Dr. Edward Moore, Albany, New York:

My Dear Sir: Your letter of the 1st inst. received. I have to say that we have issued two bulletins on tuberculosis, but regret to say that the edition of one of them, No. 101, is exhausted. I, however, send you under separate cover Bulletin No. 118. In reference to your question as to whether I have any personal knowledge of a human being contracting tuberculosis from the bovine, I have to say that I have no personal knowledge of such a transmission of the disease.

Very truly yours,

Edward B. Voorhees, Director.

They had a herd largely infected with tubercle, and Professor Voorhees is one of the ablest writers on agricultural subjects connected with any of our State experiment stations.

ELLERSLIE STOCK FARM, RHINECLIFF, N. Y.

Dr. Edward Moore:

Dear Sir: Replying to your letter to ex-Governor Morton, will say the fifteen cattle that were killed here in 1893 were from selections made entirely from herds in this country, and not from importations. They had been recently purchased and not bred on the place.

Since the last herd was made up there has been an occasional response on testing with tuberculin, and these animals have been invariably killed.

So far as I can find, there has never been any trouble arising from the use of our milk.

Respectfully, Charles H. Royce,
Superintendent.

Dr. Edward Moore:

Dear Sir: Replying to your inquiries in regard to the contagiousness of tuberculosis, would say that it must have been in my herd for six or seven years. Have never seen any bad effects upon any one who has used the products of the cattle or had the care of them.

Very truly yours.

This gentleman has a family of five young children who have used the products of this herd all their lives, and ninety per cent. of the milk-producing animals were infected.

CHATHAM, N. Y., March 2, 1899.

Dr. Edward Moore:

Dear Sir: None of the people who ate butter or milk from the cows that were affected with tuberculosis, which you killed, have ever been afflicted with consumption. Of course, I do not know who used the butter I sold to the stores, but I do not recollect of but one case of consumption in Chatham during the time I owned those cows, or since then, and I do not think that person ate any of my butter. If I am able to furnish you any further information I will gladly do so.

Yours truly,

Albert E. Tracy.

About fifty per cent. of the herd were tuberculous.

FLOHRAM FARMS, H. McK. TWOMBLEY, Proprietor.
MASSON, N. J., April 13, 1899.

Dr. Edward Moore, Albany, New York:

Dear Sir: I can not give you any evidence either pro or con. Looking back twenty years, the length of my experience with dairy cattle, I can not recall a single person dying from consumption whose work was connected in any way with cattle or that consumed the milk.

Some four or five years ago Dr. Austin Peters told me of a case where he hoped to establish a connection between two tuberculous cows and the death of one or two children that had used the milk. At that time the evidence was not conclusive, and I never heard whether continued investigation proved anything.

I have often asked others, being greatly interested, whether such a connection had been established, but never received an affirmative reply.

Regretting that I can not be of greater service to you, I am, Very truly yours,

J. L. Hope, Superintendent.
Mr. Hope has had large experience with fine cattle, and was formerly superintendent for Hon. Levi P. Morton.

April 14, 1899.

Dr. Edward Moore, Albany, New York:

Dear Sir: Replying to your inquiry, I would state that two years ago my herd was examined by the Connecticut authorities and thirteen killed, this including everything that was suspicious. Prior to this the milk had been used freely by my farmer and his family, and one or more working on the place and their families, also in my own household, which, while in the country, includes a daughter and her three young children. Since that time the same persons have used the milk, cream, and butter, and, to the best of my belief, every one of them is in good health and looks as well as Mr. Crand's family, whom you know. I should say that, including Mr. Crand's family, there must have been during the summer at least ten adults and eight or ten children using the products, not including household servants. I do not know of a case of consumption or any indications of it in any of the persons referred to.

Very respectfully yours.

The above letter is from one of New York's prominent financiers, and his herd is one of the best in Connecticut, and, owing to the large percentage of diseased animals, and the number of children as well as adults who have been feeding on their products for a number of years, this evidence is exceptionally strong.

If we have succeeded in purging the bovine of responsibility for human tuberculosis we have severed the relation supposed to exist and which gave origin to the title of this paper. People everywhere will feel relieved. Cattle owners will vie with the cow-milk drinkers and the beef eaters in their appreciation of the fact that their minds are now freed from the terrible menace that has heretofore haunted them. The cattle industry will receive new impetus. Physicians will have to educate consumptives to appreciate the necessary precautions they should take, nay, they must take, for the protection of their fellow beings, and healthy people must be made to understand in what ways tuberculous subjects are dangerous to them. The imperative need is for measures for the protection of human from human. Such education will cut down the death-rate more rapidly than medical treatment. The establishment of hospitals and retreats for the treatment and isolation of consumptives is the best step physicians have yet taken for the prevention of the spread of this disease. We are now raising one foot to step up on to the firmer ground of the twentieth century, where no erring footsteps have yet been taken. In the few days left us ere we reach that new tryesting place, let us bend our energies to the great task of leaving forever behind us old prejudices; theories we were taught to accept, but which have not proved trusty; deductions arrived at from experiments well intended, but which are nullified by better evidence now before us. Let us not look at things as they have been pictured, but strive to see them exactly as they are. If we have failed to convince you, we have at least pointed the way for future investigation and given the earnest of the verdict that is to follow whether you render it to-day or to-morrow.

DUST

IN THE ETIOLOGY OF TUBERCULOSIS.

By MAX GIRSDANSKY, M.D.

Tuberculosis is justly called the scourge of the human race, for it is not only a very fatal but also one of the most widely spread maladies of the animal kingdom, and especially of the human race. Many competent observers have undertaken the laborious task of determining more or less approximately the frequency of tuberculosis; and although the results of their labors seem to vary slightly in details, the general outcome of their observations seems to be the same.

Of all the bodies examined at the morgues and hospitals of the large cities, between thirty-three and seventy-five per cent. have shown macroscopic lesions of tuberculosis. Dr. Schlenker has made a careful examination of one hundred bodies of adults and children for that purpose. He made a careful autopsy of each body, giving special attention to the lungs and cervical, bronchial, and mesenteric glands; caseous and calcareous processes were regarded as tuberculous; simple adhesions were not regarded as such. The examinations were almost entirely macroscopic. Out of the one hundred bodies thus examined, sixty-six were tuberculous.* These figures are quite significant.

As to the cause of tuberculosis all agree now. After thousands of independent experiments and investigations it has been proved that Koch's Bacillus tuberculosis is the essential element in the causation of tuberculosis.

As to the ways in which the bacillus gains admittance into the human body, all seem to agree as well; ordinarily three avenues are recognized:

1. Food.—Since tuberculosis is quite common among the vertebrata, many of which serve man as food, the milk and meat of sick animals, when used as food, become important means by which the Bacillus tuberculosis gains an entrance into the human body.

2. Inheritance.—Although ordinarily the offspring inherits only a predisposition to disease, direct inheritance doubtless may occur—more frequently from the female parent, possibly also from the male.

3. Inhalation.—But in the overwhelming majority of cases the tuberele bacilli gain admittance into the

human body through the organs of respiration. The
frequency with which foci are met with in the lungs
and bronchial glands is extraordinary indeed. The sta-
tistics of the Paris morgue show that a considerable
portion of all persons dying by accident or suicide pre-
sent evidence of this disease in these parts. The post-
mortem statistics of hospitals show the same widespread
prevalence of infection through the air-passages.
Briggs reports that more than sixty per cent. of his
post-mortem showed lesions of pulmonary tuberculosis.
† These and many other similar facts tend to show
that inhalation is the road of all by which the bacilli enter the system. But bacilli do not enter the
lungs of the well directly from the lungs of the sick;
for, as we all know, the breath of tuberculous patients
is not infective. The road is rather an indirect one: Pa-
tients with moderate or advanced pulmonary tuberculosis throw off daily a large amount of sputum containing
millions, even billions, of bacilli. This sputum,
thrown indiscriminately upon the floor, sidewalk, or
street, is rapidly dried, pulverized, and converted into
dust, to the minute particles of which countless num-
bers of bacilli adhere, thereby becoming part of the air
we all inhale, and thus getting free and easy access to
the pulmonary system.
It is necessary to emphasize, however, this well-
known fact that the sputum is harmless until it is dried,
pulverized, and disseminated into the air; then, and
only then, does the sputum of the sick become a means
of transmitting the deadly germs from the sick to the
well. It is therefore self-evident that everything tend-
ing to produce and maintain dust in the air thereby
tends also to maintain the fearful spread of tuberculo-
sis; not to mention also probably that of scarlata,
measles, influenza, and many other infectious diseases.
It is ordinarily supposed that dust in our city air
is produced by the friction offered by the footsteps of
man and animal, by the wheels of vehicles, and by the
action of the wind.
I wish to call your attention to one agent whose
grewsome power in this direction is greater than that
of the other agents combined. I mean the broom.
The foot is an easy, thoughtless affair. The broom
is applied with a great deal of attention, intention, and
vigor. The footstep has its habitual narrow path, and
seldom roams out of it. The broom shuns negligence,
and prides eagerly into each forgotten corner. The aim-
less footstep is put down carelessly and may be insuf-
ficient to break up the crust formed by the pathological
sputum. The action of the wind is weak, uncertain,
and frequently tempered by the inhibitory influence of
the shower. But when the dutiful housewife comes out
in the morning with her sceptre of power—her broom—to
do the housecleaning, cleanliness becomes the watch-
word, and thoroughness the motto of the hour. She
enters upon the field with energy worthy of a better
purpose. With her broom she rubs and scrapes, and
scratches and scratches, and rubs and scrapes again
until all noxious matter has been loosened, pulverized,
and gathered out of its hiding place. She whips and
grates and brushes until the room is filled with a cloud
of dust; not an inch of floor is left undisturbed, not a
corner unswept.
After an hour's such exercise she has cleaned her
room and gathered the dirt out of the house. But the
dirt that she has actually cleaned out of the house is of
the more innocent variety: pieces of fruit, pieces of
bread and meat, large or moist particles of sand, wear
and tear of clothes and furniture, pieces of paper, etc.
The really noxious variety, the dried sputa, contents
of the nasal and rectal cavities, all waste products of
man or animal, skin shed by convalescents or scarlet
and similar fevers—these have been broken up into the finest
particles, thoroughly pulverized, and again and again
flogged violently into the air, to be inhaled by this very
industrious house-cleaner, by her children, and the mem-
ers of her household. The clouds of dust her broom has
raised are so thick that she feels the necessity to pro-
tect her hair and to cover her clothes and furniture;
she does not give a thought to her lungs: perhaps she
is not aware of having any.

The cleaning of the carpet, of the mat, and the hall
rugs comes next. These are thoroughly shaken, hung
out from the windows, from the lines, occasionally
waved in the street or upon the roof; dusted, shaken,
and beaten until they are rid of all their dirt; until
all this has been converted into fine dust flogged into
the air, in which it is kept perpetually floating until it
reaches its permanent destination—the bronchial mucous
membrane of the passer-by.

Thus the process of sweeping, although apparently
accomplishing its purpose, in reality serves as the most
effectual means of spreading tuberculosis, the scourge
of the age.

But the sweeping is not the function of the house-
wife or servant only. The finest particles of wear and
tear of the household have been thrown out on the
street, the dust entered many a bronchial tube, but a
part of it has settled upon the furniture, walls, and ceil-
ing of the house; there, however, not to remain for a
very long period, for the dusting hour will arrive—all
will be stirred up, all dust will be disseminated, and all
bacilli floating again, until as many of them as possi-
ble will safely settle in some trachea, bronchus, bronchi-
ole, or pulmonary vesicle. In the afternoon or next
day this process is repeated.

That part of the dirt that has been removed to the
street, and that part of the dust that has been allowed
to escape through the opened windows, has entered into
the domain of another knight of the broom—the
janitor. He exhibits, if anything, certainly not less

---

* Osler. The Principles and Practice of Medicine, second edition, p. 209.
zeal than the housewife. The house dust and dirt that has mingled with the particular dirt of the sidewalk—viz., the expectoration of the passer-by and the excreta of domestic animals—is again rubbed and brushed and puffed into the air; then, again, the bacilli are offered an easy chance to enter the lungs of the speed- ing broomwinner or school-going innocents.

Nor is this the end of the story. Removed from the sidewalk, the dust and dirt, in emerging from the domain of the janitor, have entered into the kingdom of a new potentate—the street sweeper. This functionary, in possession of a broom of monstrous dimensions, has dust-producing as his special duty; he sweeps the dirt into small heaps, the small ones into the larger ones, the larger ones he throws into barrels, from the barrels he throws the dust into wagons, from the wagons it is thrown into boats, from the boats it is thrown into the sea. Each of these performances is carried out with such violence that a cloud of dust marks the wake of the street-cleaning functionary. At the pier where the wagons empty their contents into the float, the houses, yards away, are covered with a dust film so thick as to enable one to read letters traced with the finger upon the wall.

The mode of cleaning the street and house, especially if the latter is carpet-covered, by sweeping, as commonly practised, accomplishes the following:

1. The broom breaks up all dried sputum, excretions of the nasal and rectal cavities, and excretions of domestic animals; it frees the micro-organisms contained in them, and thereby transmutes these low organisms from an innocuous, latent, potential state into a nascent, kinetic, virulent condition.

2. Having been the main instrument for the consumption of this change, the broom, by reason of its frequent use, becomes also the main, almost the only, instrument by which the bacterin-laden dust is kept perpetually floating in the air, stirring it up again and again as soon as it settles through the action of gravity.

3. It keeps constantly floating in the air the skin shed by convalescents of scarlatina, measles, and similar conditions, and is probably performing a similar function in seventy-five per cent. of all known infectious diseases.

It has been stated repeatedly that even in the high mountainous regions proverbially free from tuberculosis, this pest has been introduced with the spread of civilization in these regions. Thus the late A. L. Loomis states: "Mountains and elevated districts were thought to be beneficial on account of their elevation alone. But recent investigations show that the absence of atmospheric impurities is the chief element, and that the purity of the air is the chief reason that elevated regions are so beneficial in phthisis." *

4. And again, "Elevation was regarded also as the cause of this immunity from phthisis. This theory was disproved by the fact that whenever the inhabitants of elevated regions engaged in manufacturing pursuits which confined them in unwholesome air, phthisis was frequently developed." *

The following is from Freudenthal: †

"I should like here to explain my views in regard to the supposed immunity of certain places against tuberculosis, of which we formerly heard so much. . . . With the increase in factories and workshops, together with the confinement in close quarters of large numbers of people, tuberculosis sets in without fail, whether this be at Dawson, Goerbersdorf, or Denver; as a striking example permit me to mention Chaux-de-Fonds, a small place in Switzerland, where tuberculosis is responsible for as many deaths in a thousand as it is in Berlin. Yet Chaux-de-Fonds is situated three thousand feet above the sea, in the midst of extremely healthy surroundings, in the Jura Mountains. The prevalence of tuberculosis here is due to the watch factories, for which it is celebrated."

Thus we see that tuberculosis advances in step with civilization.

It is, of course, understood that from this viewpoint the word civilization stands for no one single condition, but rather for a combination of conditions of overcrowding, wretchedness, and all the unhygienic surroundings of the laboring class. I would, however, suggest that the broom, and to an extent also the carpet, ought to come in for a full share of the responsibility of tuberculosis under civilization as thus defined.

If sixty per cent. of all men die of pulmonary tuberculosis (Biggs)—if the main, almost the only, cause of pulmonary tuberculosis is bacilli-laden dust, and the broom by far the main cause for such dust, the broom is evidently responsible for more deaths than the sword ever was.

The inevitable consequences of the above are:

1. That the broom, far from serving any hygienic purpose, is the cause of the maintenance of organic dust in the atmosphere of the large cities of the world, and as such is the most important cause of the existence and spread of tuberculosis, probably also of various other infectious diseases, and should therefore be abolished.

2. That the carpet is an unhygienic article serving as a fine breeding ground for vegetable parasites, necessitating the use of the broom and the duster, and thereby becoming a reason for the existence of organic dust.

3. That the only proper and safe way of procuring cleanliness of the floors and streets of our large cities is by the free use of water as a cleansing agent in the shape of showers, sprinkling wagons, hose, mops, etc.

* Supplement to Ziemssen’s Cyclopaedia, pp. 329, 330.
† New York Medical Journal, March 26, 1898.
4. That all floors and floor coverings of the home and the street ought to be so constructed as to facilitate the free use of water in the shape of shower or mop as a means of procuring cleanliness.

And there is no way out of these conclusions. If all the work, research, and investigation gone through by a host of scientists during a whole generation point to dust as the practical cause of tuberculosis as well as of other infectious diseases—if science has proved that dust is the cause of more deaths than any other single condition, earthquakes, floods, and wars not excepted—are we to allow the deadly dust producers to parade under the usurped name of hygiene implements? Are we to allow the murderous street brooming to go under the name of street cleaning unchallenged? Or is it not rather our duty to issue a warning to the public to call things by their right names, to point out the real role of the broom in unmistakable terms, and to show up the enormous danger to public health that arises from mistaken ideas of cleanliness, and the fearful slaughter produced by the idiotic methods used for carrying out such mistaken ideas?

A CASE OF TETANUS TREATED WITH CARBOLIC ACID.

By D. FlaFav WOODES, M.D.,
Physician to the Presbyterian Hospital, Philadelphia.

Having seen many cases of this dreadful nervous disorder treated in many different ways in hospital and private practice, I cite this case and its treatment as the only one I have ever seen recover.

On May 24th I was called to see a boy, aged about twelve years, who had tred ten days before on a sharp nail, which penetrated about the middle of the sole or plantar part of the foot to the extent of about half an inch. The foot was poulticed, and at night ham fat was applied. This I learned from the mother of the boy. The lad told me his foot felt quite numb at the time of the accident and gave him considerable pain.

The wound gave rise to little further disturbance, and no doctor was called until several days after the accident. Then the wound was apparently healed.

When I first saw him there was stiffness of the muscles of the neck and spine; he complained of sore throat and swallowed even water with great difficulty. Aside from general lassitude the day before, I learned that these were his first symptoms, and recognizing them as grave, I advised that he be sent to a hospital. To this his parents objected, his mother crying out that "she now knew he had lockjaw, and would prefer that he should die at home."

Intense rigidity extended along the neck, back, chest, abdomen, and extremities. When attempting to drink, the trismus was increased. The muscular rigidity, which at first was not constant, soon assumed a general character, and his jaws were tightly locked. As the disease advanced the reflex excitability was increased—the slightest touch, the least noise, as the shutting of a door, or a slight current of air was enough to bring on a paroxysm. Perspiration was profuse, increased with each paroxysm of cramp, and the pain also was increased at that time. The expression of the face was indicative of extreme agony, and the function of respiration was seriously involved. The muscles of deglutition were so rigid that it was impossible for him to swallow until the third day. Frothy mucus ran out of his mouth. Dyspnea and opisthotonus came on with the first spasm and remained until the system relaxed. The temperature was never above 102° F., pulse never above 86. Bowels constipated; urine scanty, high-colored, and with an excess of phosphates. He was sleepless until the third day. Throughout the whole course of the attack his mind was perfectly clear.

Treatment.—The place of injury was freely opened and a dark tarry substance (altered blood) was scraped out. The foot was then soaked in a weak solution of carbolic acid and warm water for about half an hour.

As it was impossible for him to swallow, ten minims of a ten-per-cent. solution of carbolic acid were used hypodermically; fifteen minutes after the first, twenty minims were injected; fifteen minutes after the second, thirty minims were used. Thirty minims were continued throughout the day every half hour with half a grain of cannabis indica; at night the cannabis indica was discontinued, the pupils of his eyes being at this time very contracted. The carbolic-acid solution was administered through the night, according to circumstances. If comparatively quiet, he was not disturbed, but when the interval was prolonged the dose was increased to a drachm hypodermically. There was considerable amelioration in the spasms on the second day, and the solution of carbolic acid was only administered hypodermically every two hours in half-drachm doses of a ten-per-cent. solution. This treatment was kept up until the morning of the third day, when he could swallow. Then a drachm of the solution in glycerin was administered every three hours until the spasms ceased. After the spasms ceased a drachm three times a day was given, and gradually diminished to half a drachm three times a day and kept up until all rigidity had left. Up to the third day the patient was nourished through the bowels with milk, eggs, and brandy. On the afternoon of the third day he slept for two hours, seemed refreshed, and said he felt better. From this time on he continued to improve, but the rigidity did not entirely leave him for three weeks after the attack. When he began to relax, his bowels were freely moved and his kidneys acted profusely. His urine soon after the carbolic acid was administered had the characteristic odor of the drug, and the smoky appearance was manifest on the second day. No perceptible irritation of the kidneys or bladder followed, and no permanent pernicious sequelæ. He was weak and generally debilitated by the attack, but soon recuperated.

He is now to all appearances perfectly well.

From this case I learn that carbolic acid in tetanus is effective only in large and heroic doses. Under these circumstances it is surprising how much the system will bear. I believe that carbolic acid acts as an antitoxine and is much more reliable than any serum which I have seen tried. If given boldly as early as possible, so that the system may be quickly and completely saturated, its antiseptic influence will be manifest on the blood, and I believe there is great hope of this agent becoming
a great boon to humanity in the cure of this distressing and alarming malady.

Shortly after the convalescence of this boy I learned through Captain Wolcott, civil engineer of the United States navy at League Island, of a case of tetanus in one of their horses, cured by the use of carbolic acid, on my suggestion of that treatment.

I append the report of the case by Dr. H. B. Cox, veterinary surgeon:

The following is a report of a bay gelding, six years old, owned by the government, stationed at League Island Navy Yard, Philadelphia, Pennsylvania:

My attention was called to the horse, which I saw was suffering from the above-mentioned disease, with all the characteristic symptoms; a few of the most prominent I will describe as follows: The muscles of the head and neck were so rigid that movement of the head to either side was impossible; the nose elevated and poked out; the nostrils dilated; the visible mucous membrane reddened and congested; ears stiff and erect; the membra nobcitan drawn back, almost covering the eye; the jaws almost locked, only able to pry them open about an inch; the muscles of the croup and back hard and stiff; legs stiff and stood out like four posts; almost impossible to raise the feet far enough to prevent stumbling. The patient also had frequent paroxysms, especially when excited; tail raised erect and stiff; pulse hard and frequent; respiration hurried; temperature high. The cause can be traced to the docking of the tail. The symptoms were so pronounced that recovery seemed impossible.

I finally decided to give the carbolic-acid treatment a fair trial, the result of which has proved very satisfactory.

The following is a daily report of the case: The external treatment consisted of cleansing the wound thoroughly three times daily with a fifteen-per-cent. solution of carbolic acid. The internal treatment: I prescribed six drachms of a ten-per-cent. solution every three hours, gradually increasing the dose until I reached an ounce and a half of ten-per-cent. solution every three hours, until the stiffness began to disappear. Then I gradually decreased the dose.

I will proceed with the daily condition of the patient.

**July 22d.**—The patient's jaws have unlocked completely and he is able to take his three meals every day; also rests easily through the night; lies down and gets up without the slightest difficulty—in fact, the horse has fully recovered, with the exception of a slight stiffness due to standing on plank floor, which will leave him in a few days.

I highly recommend this treatment, and am pleased to know that some we have found something that will overcome the dreaded disease of tetanus.

1501 Spruce Street.

---

**Therapeutical Notes.**

**A Mixture for Incontinence of Urine and of Fæces in General Paralysis.**—M. Athanassio (Indépendance médicale, August 16th) recommends the following:

\[
\begin{align*}
\text{Tartrate of iron and potassium} & \quad 15 \text{ grains;} \\
\text{Tincture of nux vomica...} & \quad 15 \text{ to 20 drops;} \\
\text{Decoction of rhathany,} & \quad 1,500 \text{ grains.}
\end{align*}
\]

M. The mixture to be taken a soupspoonful at a time in the course of forty-eight hours.

**Citropheuma.**—Boehm, of Barnem (Deutsche Medizinal-Zeitung, July 31st), says of this compound of phenetidine and citric acid that it is rapidly decomposed by the gastric juice, as is shown by the fact that paraphetidine may be detected in the urine in twenty minutes after the drug is taken. On account of its agreeable taste and its freedom from ill effects, he has used it instead of such other analgesics and antipyretics as antipyrine and acetonilide, giving from seven to fifteen grains twice or three times a day to adults, and from a grain and a half to four grains and a half to children.

**For Painful Dysmenorrhœa.**—The Progrès médical for August 5th, citing Presse médicale, attributes the following to Dalche:

\[
\begin{align*}
\text{Ergotine} & \quad 1 \frac{1}{2} \text{ grain;} \\
\text{Sulphate of quinine} & \quad \frac{3}{10} \text{ grain.} \\
\text{Powdered digitalis leaves} & \quad \frac{3}{10} \text{ grain.} \\
\text{Powdered coca} & \quad 4 \text{ grains.}
\end{align*}
\]

M. For one pilule. From three to five may be taken daily.

**Confection of Cinchona.**—Riforma medica for August 5th attributes the following formula to Brissemoret:

\[
\begin{align*}
\text{Caffeine} & \quad 45 \text{ grains;} \\
\text{Extract of cinchona} & \quad 187 \frac{1}{2} \text{ grains}; \\
\text{Citric acid} & \quad 30 \text{ grains;} \\
\text{Tincture of vanilla} & \quad 7 \frac{1}{2} \text{ grains;} \\
\text{Alcohole of citron pcel} & \quad 30 \text{ grains;} \\
\text{Rum} & \quad 600 \text{ grains;} \\
\text{Syrup} & \quad 2,250 \text{ grains;} \\
\text{Gelatin} & \quad 150 \text{ grains;} \\
\text{Glycerin} & \quad 600 \text{ grains;} \\
\text{Water} & \quad 1,350 \text{ grains.}
\end{align*}
\]

M. Take as much as will lie on the point of a knife (sic) daily.
THE NEW YORK MEDICAL JOURNAL.
A Weekly Review of Medicine.
Published by D. APPLETON AND COMPANY. Edited by FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, SEPTEMBER 9, 1899.

THE PLEA OF INSANITY IN CRIMINAL CASES.

In the Journal for July 8th, in an article entitled The Insanity Problem, we said: "There should be no known lunatics at large, however 'harmless' they may be rated. The public hardly seems to appreciate the danger it is in from the outbursts of insane propensities, and this, it is to be suspected, is in great measure due to the community's sense of self-preservation having been drowned in a sentimentality that has been aroused and is continually nourished by harrowing tales of sane persons wrongfully immured in asylums and of the cruelties alleged to be practised in such institutions. Nevertheless, the danger is great."

This contention has been ably upheld in the writings of Dr. H. E. Allison, the medical superintendent of that one of the New York State lunatic asylums which is known as the Matteawan State Hospital, an institution to which the criminal insane are largely committed. For a most forcible argument in favor of the position we would refer the reader to an abstract of one of Dr. Allison's articles (published in the April number of the American Journal of Insanity) which we printed in our issue for June 10th. The July number of the Albany Medical Annals contains another example of Dr. Allison's able presentation of the subject, being his contribution to a discussion of it by the National Prison Association of the United States at a meeting held in Indianapolis some ten months ago. In this article the author reaffirms his conviction that the insane with propensities to commit acts which society regards as criminal, while irresponsible, should be recognized as insane and committed to an institution for the criminal insane, there to remain, not for some period prescribed by the law on the basis of the offense, but until it is clear that they may be set at large or transferred to other surveillance without danger to the community.

While Dr. Allison concedes that the plea of insanity is sometimes resorted to dishonestly and as a mere subterfuge in behalf of sane villains, he thinks that, on the whole, the plea ought to be set up oftener than it is, for, if it was shown to be well founded, the individual, although acquitted of criminal responsibility, would be committed to proper care, and society would be protected rather than endangered, as it would be by his release after a specified term of penal imprisonment. The popular contempt for the plea is no doubt based largely on distrust as to its genuineness, but, except in a small percentage of doubtful cases, this can always be ascertained to the satisfaction of the court and the jury, although not most readily by the "hypothetical question" that is so dear to the criminal pettifogger. The popular opposition to the plea as a bar to execution or penal servitude is probably due in great measure also to the fear that its admission may deprive the trial and its result of the deterrent influence that the condign punishment of offenses is supposed to exert and doubtless does exert upon some persons of vicious and criminal tendencies; in other words, the fear that other offenses may be encouraged if one offender is sent to an asylum rather than to the gallows or a prison. This is a practical view of the matter, one wholly free from unfounded distrust on the one hand and from morbid sentiment on the other; but it is met by the inevitable conclusion to be drawn from the facts presented by Dr. Allison and others to the effect that the community is protected against an insane criminal only for a time if he is sentenced to a specified term in prison, but is left defenseless against him on his release. We repeat, "there should be no known lunatics at large."

THE VALUE OF A MEDICAL DEFENSE UNION.

We have referred several times of late to the great advantages of a medical defense union for the protection of the members of the profession against blackmail, charges of professional incompetence, etc. A case which has recently occurred in England emphasizes the value of such a league in so marked a manner that we can not refrain from laying the gist of it before our readers.

Dr. Kidd, a medical man in practice at Bromsgrove, whose diplomas of M. B. London and F. R. C. S. England mark him at once as a physician of standing, was the medical officer of the Bromsgrove sanitary district, and also of the joint isolation hospital established for the three sanitary districts of Bromsgrove, Redditch, and Droitwich. On September 17, 1898, a member of the Bromsgrove urban district council made a public allegation, according to the Lancet for August 12th, that a "patient was in the hospital one week and three days and never saw the doctor once, and all the six weeks and three days she was there she never had one drop of medicine." Further, according to the Lancet, it was alleged that, although a patient (a little girl)
was in great agony for two days, the medical officer did not see her, and that she was frightened by a threat of being put into "boiling blankets" to make her keep quiet in bed; that the medical officer actually ordered this treatment, and that the girl died while undergoing it. Moreover, it was stated that "men, women, youths, and boys and girls had to eat, drink, lie, and sleep all in one room"; also that the hospital was so badly constructed that rain came into the building, and that the wind could be felt by the patients as they lay in bed.

The facts of these allegations appear to have been that the patient in the first case "was admitted (into hospital) at a late stage of the disease, that convalescence was not interrupted, that she required no medicine, that it was not true that Dr. Kidd did not see her for ten days after her admission, and, further, it was shown that she was the defendant's aunt. The little girl was niece to the woman already mentioned. Nephritis set in as a complication of scarlet fever and she died from uraemia. A hot-pack was ordered as a means of treatment—hence the statement about 'boiling blankets'—but the disease was too far advanced for it to be of any avail. It was also proved that Dr. Kidd was indefatigable in his attendance on the patients. The hospital was only a temporary one—a hospital marquee tent with double canvas walls. It was well ventilated, but when there was heavy rain the water trickled down in one or two places, the beds, however, being carefully removed from the damp. The patients were mostly young children, but while the woman already referred to was an inmate there were two boys as patients, about fifteen or sixteen years old. They occupied the same large tent, but their beds were thoroughly screened off from the other beds and Dr. Kidd had heard no complaints."

It is easy to see how such charges may have arisen without malicious intent, and it is still more easy to comprehend how they might form a serious basis for malicious persecution.

It so happened that, according to Dr. Kidd's letter published in the same number of the Lancer, he became a member of the Medical Defense Union five years previously, little thinking that he was himself likely to become involved in litigation. But suddenly there came upon him these damaging charges of gross professional incompetence and negligence; charges which, as he says, he would certainly have been unable to deal with adequately on his own slender resources. He sent the facts to the secretary of the Medical Defense Union, and at once received a most careful and exhaustive letter of advice from their attorney, followed by an eminent counsel's opinion. The union subsequently took the case off his hands, bringing an action for libel against the author of the charges, entirely vindicating Dr. Kidd's character, disproving the allegations in detail, and obtaining for Dr. Kidd a verdict for £150, the foreman of the jury taking care to explain that it was only the defendant's pecuniary position which prevented them from assessing much heavier damages against him.

It is not only the cost of the proceedings, when an incriminated physician has either to defend himself against malicious or otherwise unjust action, or to vindicate his character against slanderous statements by bringing suit himself against their author—a cost which must inevitably be considerable even though he gain his case; but it is the wear and tear, the sleepless nights, the worry and anxiety, the unfitness for good work which comes from being in a state of tension, which are also saved to him by his membership in such a union. On this point Dr. Kidd says:

"During the six months over which the action was pending, the whole of the work connected with the case was taken off my hands by the solicitor to the union without the slightest trouble to myself, and I need scarcely have been aware that I was involved in any proceedings at all; but the work was being done nevertheless with an amount of skill and care and unwearied labor which it would be impossible to praise too highly, and which could not have been exceeded if I had been the most wealthy and exalted client in the land, instead of a humble country medical man. When I think," adds Dr. Kidd, "of what the union has done for me in this trying case and of what I should have suffered without its powerful and kindly aid, and when I reflect that such advantages are open to every member of our profession at the cost of 10s. 6d. yearly, it becomes a matter of surprise to me that the membership roll of the Medical Defense Union is not identical with the Medical Register and Directory."

In addition to these considerations, the fact must not be lost sight of that the existence of such an association would act as a strong moral power in checking ill-advised and unwarrantable actions against physicians; for not only would the knowledge that the physician had the association at his back act as a deterrent, but further, the necessary preliminary examination of his case by the union before expounding his cause would of itself testify that he stood well with the profession, and be, moreover, a presumptive cause for his assailants to expect failure.

In this country, we believe, slanderous charges are more prevalent, actions for malpractice more common, and attempts to extort blackmail from physicians more
EDITORIAL ARTICLES.

RÖNTGEN-RAY PELVIMETRY.

We do not recall having seen any account of the use of Röntgen pictures in pelvimetry prior to the appearance of an article by Fabre in Lyon médical for July 23d, and even that author does not seem to have resorted to their employment on the living subject. Such pictures have thus far been depended upon more to show form and locality than to record dimensions. No doubt, as Fabre remarks, this has been owing to the aberrations of dimension shown in the pictures—aberrations difficult if not insusceptible of correction by ordinary means. Acting on suggestions made by Fochier (Province médicale, June 24th), Fabre has, however, made satisfactory observations of the dried pelvis, but, as we have already said, does not seem to have applied his method to the living woman. The procedure is very simple, and it might be turned to practical account in obstetric pelvimetry. The essence of it is the placing of a serrated strip of metal in front of the object to be observed, and at a measured or closely estimated distance from it, each space between adjacent serrations being of a uniform and known extent, a centimetre or any convenient fraction of an inch. The image of this serrated strip of metal would serve as a scale for the rest of the picture.

What possibilities there seem to be in such a method of pelvimetry! Away with callipers and all other mechanical pelvimeters! Here is a process that will accurately register the various dimensions of the superior and inferior straits, define the axis of the bony parturient canal, and lay down contour lines of the passage the fetus has to traverse. Röntgen-ray observations of the pelvis, of course, could be more readily made when the woman was not pregnant, but there is no serious bar, apparently, to their being very serviceable at any time, even up to the setting in of the actual process of parturition. Pelvimetry has heretofore been a somewhat inaccurate process, even in the hands of the expert and with no matter what instruments, but now, with the aid of the Röntgen rays and the scale graduated in notches, nothing, it would seem, can be simpler than to secure an undeniably correct representation of the shape and dimensions of the pelvis in all its details, and that, too, without so much as ruffling my lady's precise attire. The exposure, we take it, need not be protracted, and consequently the risk of burns will be practically nil.

THE TORONTO MEETING OF THE CANADIAN MEDICAL ASSOCIATION.

It was to be expected, from the staid and well-balanced character of our Canadian brethren, that the Toronto meeting would keep steadily at its work regardless of the attractions of the industrial exposition that was going on in the city at the same time. And so it turned out; the ample programme was not slighted, and the meeting was profitable in an uncommon degree. Entertainments there were, indeed, as there could not fail to be in a place having such facilities for them as Toronto has, and one whose people are so hospitable; but they were according to previous arrangement and did not interfere with the association's real work. The compliment of assigning the address in surgery to an American, Dr. Coley, will be appreciated by the profession in the United States, and it may not be superfluous to mention the fact that the Americans present were gratified to see the Stars and Stripes among the decorations of the hall. We are happy to believe that the respect and good-will cherished by the medical profession of the two countries for each other will never be disturbed by the machinations of politicians or the greed of money-makers.

MORE NEWSPAPER MEDICINE.

One of the newspapers recently announced that a physician had certified that a man had died of ophthalmia, which it described as "a first cousin to tetanus."

AN EARLY OPponent OF CRANIOTOMY.

It is but a few years since craniotomy was one of the recognized resources of obstetrics. Although, we think, it was never looked upon with favor in the United States, still, it required a good deal of courage to condemn it in Iola. One of those who had that courage was Dr. Bousey, of Washington. At a recent meeting of the Washington Obstetrical and Gynaecological Society Dr. Henry D. Fry, at the close of a paper entitled The Surgical Treatment of Unrotated Occipito-posterior Positions (American Journal of Obstetrics, August), thus brought to mind Dr. Bousey's position: "It was in the infancy of the organization when our venerable founder and first president took the ground that craniotomy was never justifiable upon the living child.
His position was assailed at home and abroad and led to the publication, in one of our most prominent journals, of an able but severely sarcastic criticism. At that time the revived sympyohotomy operation with its low mortality was not known. The only substitute for craniotomy was the improved Casarean section, which had just begun to win the confidence of the profession. Through all the storm of adverse criticism Dr. Busey remained silent and waited for Time, the great arbiter, to set him right. He has lived to see the majority of the profession come around to accept views which he advanced ten years before their time.

A POISONOUS SPIDER OF THE TROPICS.

In temperate climates we think little of poisonous spiders' bites, though they are occasionally encountered. In the tropics, however, they figure more largely in general practice. G. Braun (Wiener medizinische Presse, 1899, No. 6; Centralblatt für innere Medizin, August 12th) writes of the bite of Latrodectus tredecim punctatus as giving rise to diffuse pain, great restlessness, sleeplessness, and prostration. In one case he observed a rash resembling that of scarlet fever, and once there was retention of urine, but the latter is said to occur only when the bite is on the lower half of the body. Recovery occurs in from three to five days.

ACCIDENTAL VACCINATION OF THE VULVA.

The misadventure of accidental vaccination is sometimes serious, but in a case related by Maillefort, of Magdeburg (Münchener medizinische Wochenschrift, 1899, No. 18; Deutsche Medizin-Zeitung, August 10th), the formation of vaccine pox on the labium pudendi seems to have been attended with little inconvenience, doubtless because the pox ran a rapid course in consequence of the woman's having been successfully vaccinated fourteen years before. Her youngest child had a very sore arm as the result of vaccination, and she dressed it with cloths dipped in oil. One of these cloths she afterward used for wiping her vulva, as she was suffering from an abundant vaginal discharge attendant upon pregnancy.

ABSCESS OF THE GLOSSO-EPIGLOTTIC FOSSA.

It has fallen to the lot of Lublinski (Deutsche medizinische Wochenschrift, 1899, No. 8; Centralblatt für Chirurgie, July 29th) to observe three cases of this rare affection, known also as angina preepiglottica phlegmonosa. In all of them the abscess was situated on the left side, and some difficulty of inspiration was occasioned by the epiglottis being pushed downward and backward. The abscess was very tender to the touch. It was with great difficulty that the diagnosis was made with the aid of the laryngoscope. The swelling looked grayish-red and shining, and felt pasty.

TETANY FOLLOWING PARTIAL THYREOIDECTOMY.

Much as we have learned of late years about the physiological importance of the thyroid gland, it is not easy to understand the part it plays in withstanding convulsive affections. This remark is prompted by an account of the case of a lad who was subjected to excision of the middle and left lobes of the gland for goitre. The right lobe was left, although it was about as large as a hen's egg. Four months later this remaining lobe became enlarged and indurated, and the boy was suddenly seized with spasms of the arms and then of the legs. They gradually grew milder, and subsided in the course of a week. At the same time the remains of the goitre became smaller again. The case is related by F. Schilling, of Nuremberg (Münchener medizinische Wochenschrift, 1899, No. 8; Centralblatt für Chirurgie, July 29th).

TYPHOID FEVER AND RECTAL THERMOMETRY.

There has long been reason to fear that in some hospitals rectal thermometry, practised on patient after patient by a ward attendant, was not altogether beyond the suspicion of conveying disease from one person to another. This has actually happened in a Turin hospital. Bornans (Gazetta medica di Torino, 1899, No. 19; Centralblatt für innere Medizin, August 19th) tells of three instances in which typhoid fever was so conveyed.

COTTON-SEED OIL.

It has long been known in this country that cotton-seed oil was wholesome and nutritious; furthermore, that, when properly prepared, it was as palatable as any but the best of olive oil. The Lancet, in its issue for July 29th, recognizes these facts and suggests that the oil might be used to advantage as a substitute for cod-liver oil in many cases.

DEAFNESS DUE TO MUMPS.

Like influenza, mumps is a disease more to be dreaded for its complications and sequelae than for the direct damage done by it. Fortunately, mumps occurs but once as a rule, and its complications are rare. Among them is deafness. This was long ago recognized by Toynbee, but Gallavardin has recently performed a service by going over the subject anew (Gazette des hôpitaux, December 17, 1898; Parole, June, 1899). It seems that the deafness of mumps is generally total and permanent, though it may affect only one ear. It appears early in the disease, either suddenly or as a sequel of labyrinthine symptoms like those of Ménière's disease. The pathogeny remains obscure, but most authors think there is a sanguineous effusion into the labyrinth. Treatment is of no avail as regards the power of hearing, but the vertigo may be mitigated by means of quinine.

ITEMS.

An Army Sanitarium for Tuberculosis.—The following general order No. 159, dated August 29th, has been issued from the adjutant-general's office by direction of the major-general commanding: By direction of the secretary of war, the surgeon-general of the army is authorized to establish a general hospital at Fort Bayard, New Mexico, as a sanitarium for the treatment of officers and enlisted men of the army suffering from pulmonary tuberculosis, and hereafter transfers of enlisted men suffering from this disease may be made to this hospital upon the recommendation of medical officers of the army (to be forwarded through military channels).
Such buildings pertaining to the post of Fort Bayard as may be necessary to carry this order into effect will be designated by the surgeon-general of the army. Fort Bayard will be put in good state of repair by the quartermaster's department.

The surgeon-general is also authorized to provide for the care and treatment of discharged soldiers entitled to the benefits of the United States soldiers' home, Washington, District of Columbia, who may be sent to the sanitarium by the board of commissioners of the home, the expense for the maintenance of such discharged soldiers to be paid from the soldiers' home funds.

**Infectious Diseases in New York.**—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the week ending September 2, 1899:

<table>
<thead>
<tr>
<th>DISEASES</th>
<th>Week ending September 2.</th>

**An Examination for Appointment as Assistant Physician, Junior Grade, to the Government Hospital for the Insane.**—The United States Civil-Service Commission announces that on October 4, 1899, an examination will be held in any city in the United States where the commission has a board of examiners for the position of assistant physician, junior grade. The examination will consist of the subjects mentioned below, which will be weighted as follows:

<table>
<thead>
<tr>
<th>Subjects</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1) Letter writing</td>
<td>5</td>
</tr>
<tr>
<td>(2) Anatomy and physiology</td>
<td>15</td>
</tr>
<tr>
<td>(3) Chemistry, materia medica, and therapeutics</td>
<td>15</td>
</tr>
<tr>
<td>(4) General and special pathology</td>
<td>25</td>
</tr>
<tr>
<td>(5) Surgery</td>
<td>20</td>
</tr>
<tr>

<td>10</td>
</tr>
<tr>
<td>(7) Obstetrics and gynecology</td>
<td>10</td>
</tr>
<tr>
<td>Total</td>
<td>100</td>
</tr>
</tbody>
</table>

The minimum age limitation for entrance to this examination is twenty years; the maximum none. The examination is open to both men and women, but a separate eligible register will be kept for each sex. From the "eligibles" resulting from this examination certification will be made to fill two positions in the government hospital for the insane, one from the male register at nine hundred dollars per annum, and one from the female register at six hundred dollars per annum. This examination is open to all citizens of the United States who comply with the requirements. All such citizens are invited to apply. They will be examined, graded, and certified with entire impartiality and wholly without regard to any consideration save their ability as shown by the grade attained by them in the examination. Persons desiring to compete should at once apply to the United States Civil Service Commission, Washington, D. C., for application forms 394 and 375, which should be properly executed and promptly filed with the commission.

**Marine-Hospital Service Health Reports.**—The following cases of small-pox, yellow fever, cholera, and plague were reported to the surgeon-general during the week ending September 1, 1899:

**The Buffalo Academy of Medicine.**—At the last regular meeting, on Tuesday evening, the 5th inst., Dr. A. L. Benedict read a paper entitled "The American Aborigines from a Medical and Surgical Standpoint."

**Changes of Address.**—Dr. L. S. Sobel, to 1421 Lexington Avenue; Dr. W. F. Varcoe, to 232 West Twenty-second Street.

**Army Intelligence.**—Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from August 26 to September 2, 1899:

- **BARRETT, EDWARD J., First Lieutenant and Assistant Surgeon, United States Volunteers, will proceed to Camp Meade for duty.**
Galbraith, Charles M., First Lieutenant and Assistant Surgeon, United States Infantry, will proceed to Camp Meade for duty.

Gilmour, Louis L., Acting Assistant Surgeon, will proceed to Fort Hancock, New Jersey, and report for temporary duty pending the arrival of Howard Deane C, Captain and Assistant Surgeon.

Hall, William R., Major and Surgeon, will proceed by steamer Missouri and report to the commanding general, Department of the Pacific, and to the Eighth Army Corps for duty in the Philippine Islands.

Lippincott, Henry, Lieutenant-Colonel and Deputy Surgeon-General, United States Army, will represent the medical department of the army at the eighth annual meeting of the military surgeons of the United States at Kansas City, Missouri, vice Powell, Junius L., Major and Surgeon, United States Army, relieved.

Mathews, George W., Captain and Assistant Surgeon, Thirty-sixth Regiment, is ordered to temporary duty with the Third Artillery, Malolos, Philippines Islands.

Mazzari, Paul, Acting Assistant Surgeon, United States Army, is ordered to duty in the office of the chief surgeon of the department, with station in Matanzas, Cuba.

O'Reilly, Robert M., Major and Surgeon, United States Army, is granted leave of absence for a month to visit the United States.

Pray, Gilbert L., Acting Assistant Surgeon, United States Army, is ordered to temporary duty at the General Hospital, Presidio of San Francisco, awaiting transportation to the Philippine Islands.

Robins, Robert P., Captain and Assistant Surgeon, United States Volunteers, is assigned to the Forty-seventh Infantry, and will join his regiment upon its arrival in Manila.

Wales, Philip G., Captain and Assistant Surgeon, United States Army, is granted sick leave for one month.

Weaver, Frederick C., Acting Assistant Surgeon, United States Army, is assigned to duty on the transport City of Puebla during the voyage of that vessel to the Philippine Islands.

Werr, Walter D., Captain and Assistant Surgeon, United States Volunteers, is assigned to the Forty-third Infantry, United States Volunteers, and will proceed to Fort Ethan Allen, Vermont, for duty.

Wilson, James S., First Lieutenant and Assistant Surgeon, United States Army, will proceed on the United States Hospital ship Missouri to Manila.

Wilson, Nelson W., Acting Assistant Surgeon, United States Army, will report to the commanding officer, Fort Porter, New York, for duty as medical examiner of recruits at Buffalo.

Naval Intelligence.—Official List of Changes in the Medical Corps of the United States Navy for the Two Weeks ending September 2, 1899:

England, E., Pharmacist. Detached from the Mare Island Navy Yard and ordered to the New York Navy Yard.

Grabel, C. U., Medical Inspector. Ordered to duty at the New York Navy Yard as a member of the board of medical examiners.

Guest, M. S., Passed Assistant Surgeon. Ordered to the Boston Navy Yard.

Lewis, L. R. G., Pharmacist. Detached from the New York Navy Yard and ordered home to await orders.

Stokes, C. F., Passed Assistant Surgeon. Detached from duty as a member and recorder of the board of medical examiners at the New York Navy Yard and ordered to continue on duty at the Naval Hospital, New York.

Dunn, H. A., Assistant Surgeon. Detached from the Washington Navy Yard and ordered to the Port Royal Naval Station.

Garton, W. M., Assistant Surgeon. Detached from the Annapolis and ordered to the Norfolk Navy Yard for duty on the Franklin, instead of to the Naval Academy.

Guest, M. S., Passed Assistant Surgeon. Detached from the Boston Navy Yard and ordered to the Wabash.

Hurd, I. N., Pharmacist. Detached from treatment at the Naval Hospital, Mare Island, California, and granted sick leave for three months.

Johnson, M. K., Assistant Surgeon. Detached from the Marietta and ordered to the Nashvillle.

Kerr, D. B., Assistant Surgeon. Detached from the Yankton and ordered to the Marietta.

Rosenbloom, J. C., Passed Assistant Surgeon. Detached from the Nashvillle and ordered to the Naval Hospital, Chelsea, Massachusetts, for treatment.

Stuart, A., Assistant Surgeon. Detached from the Port Royal Station and ordered to the Yankton.

Waggener, R., Pharmacist. Ordered to the Army and Navy General Hospital, Hot Springs, Arkansas, for treatment.

Society Meetings for the Coming Week:

Monday, September 11th: New York Academy of Medicine (Section in General Surgery); New York Academy of Sciences (Section in Chemistry and Technology); New York Medical-historical Society (private); New York Ophthalmological Society (private); German Medical Society of the City of New York; Gynecological Society of Boston; Burlington, Vermont, Medical and Surgical Club; Norwalk, Connecticut, Medical Society (private).

Tuesday, September 12th: New York Academy of Medicine (Section in Genito-urinary Surgery); New York Medical Union (private); Buffalo Academy of Medicine (Section in Medicine); Rome, New York, Medical Society; Medical Societies of the Counties of Rensselaer and Ulster (quarterly), New York; Newark (private) and Trenton, New Jersey, Medical Associations; Clinical Society of the Elizabeth, New Jersey, General Hospital and Dispensary; Northwestern Medical Society of Philadelphia; Practitioners' Club, Richmond, Kentucky; Richmond, Virginia, Academy of Medicine and Surgery.

Wednesday, September 13th: New York Pathological Society; American Microscopical Society of the City of New York; Society of the Alumni of the City (Charity) Hospital; Medical Society of the County of Montgomery, New York (quarterly); Worcester, Massachusetts, District Medical Society (Worcester); Philadelphia County Medical Society.

Thursday, September 14th: Society of Medical Jurisprudence and State Medicine, New York; Brooklyn Pathological Society; Medical Societies of the
Counties of Cayuga and Cortland (quarterly), New York; South Boston, Massachusetts, Medical Club (private); Pathological Society of Philadelphia.

Friday, September 15th: New York Academy of Medicine (Section in Orthopaedic Surgery); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society; Chicago Gynecological Society.

**Births, Marriages, and Deaths.**

**Married.**

FORSYTHE—WRIGHT.—In Boston, on Wednesday, August 30th, Dr. H. H. Forsythe, of Amsterdam, New York, and Miss Anna Wright.

**Died.**

CAEMMERER.—In Brooklyn, on Wednesday, August 30th, Dr. William H. Caemmerer, in the seventy-eighth year of his age.

FEELY.—In Brooklyn, on Wednesday, August 30th, Dr. James Fitzgerald Feely, in the fifty-sixth year of his age.

O’NEIL.—In Providence, Rhode Island, on Tuesday, August 29th, Dr. Timothy H. O’Neil, in the forty-second year of his age.

*Letters to the Editor.*

**SI TACUISSES, ETC.**

Philadelphia, August 22, 1899.

To the Editor of the New York Medical Journal:

Sir: I am an outisde, to say a word concerning the grammatical lapsus of my learned friend Dr. Rose, in his letter of July 23d, printed in your Journal on pages 211, 212, and corrected by Dr. Max Talmey. There is no doubt that doctor takes no ending in the vocative, and Dr. Talmey is certainly correct. Yet it is equally certain that the distinguished linguist Dr. Rose knows the Latin declensions perfectly. Still, while it does frequently happen that one commits a blunder in writing hastily, even in his own vernacular, I find another explanation for Dr. Rose’s mistake in writing “si tacuisse, doctore!” My esteemed friend is sufficiently familiar with Latin to know that doctor does not mean anything like physician in Latin, but a teacher, and that a physician in Latin is called medicus. He doubtless also remembers Medice, cura te ipsum, therefore he meant to say: “Si tacuisse, medice, philosophus manesse.” Since, however, “doctor” is eternally on the lips of a physician, speaking in any of the modern languages, the pen has run ahead of my learned friend, merely catching the tail of the word, appending the vocative of medicus to doctor. And, since a lapsus calami in Latin or Greek nowadays appears to be an enormity, it is not easily passed over, while other mistakes are securely enthroned, repeated, and taught without a suspicion. Why, for instance, do all physicians among the English-speaking nations write M. D. after their names? Why not D. M.? Surely this is the Latin order. Why LL. D.? Why D. D.? The physician is doctor medicus or doctor artis medendi or doctor medicina. The lawyer is doctor juris, and not legum; the clergyman is doctor theologiae or sacrosanctae theologiae, but not “divinitatis doctor,” which is absurd, for there is no such Latin word as divinitas for theology; divinitas means the Godhead, the divine nature, of which no clergyman is a teacher. Allow me, finally, to call attention to the Latin of the medical diplomas. I have seen revolting specimens of barbarism and ignorance in some of them. The medical profession would do well, in the interest of its own reputation, to subject them all to scholarly criticism by some committee of experts.

Arcadius Avellanus, Editor of Praco Latinus.

**THE LAW IN ITS RELATIONS TO PHYSICIANS.**

By Arthur N. Taylor, LL.B.

**XXV. CIVIL MALPRACTICE, INCLUDING GENERAL LIABILITY OF PHYSICIAN TO PATIENT.**

(Continued from page 352.)

**Deceit and Misrepresentation.**—It is a general rule of law that a statement which amounts to an expression of opinion, even though erroneous, does not furnish ground for action. Deception, to be actionable, must relate to existing or past facts, and not to representations made as to facts to transpire in the future. The reason most commonly given for this condition and the one upon which the law is probably founded is that one to whom an opinion is expressed as to a future event has no right to rely upon it. And so a purchaser may not rely upon the representation of a vendor regarding the quantity or value of an article which is open to his inspection, but must depend upon his own judgment. And also where statements were made by a real-estate agent to a widow to induce her to exchange her homestead for other property—that she was making a good trade and bettering her condition, and that she could sell enough of the other property to pay for a house—such statements are considered mere expressions of opinion and not misrepresentations; for while the person to whom such representations are made may rely upon them, he is supposed to be equally able from his own opinion to come to as correct a conclusion as the other party, and therefore cannot claim to be misled by such opinion.

As the law is always, or nearly always, based upon

† Evans vs. Bolling, 5 Atl., 550.
‡ Brady vs. Cole, 164 Ill., 116.
reason, it is natural to expect to find an exception to this general law in cases where the reasons for its existence do not apply. Such an exception does exist in those cases where an opinion is expressed with intention to deceive, and where the other party has a right to rely upon the opinion; and also in cases where the facts are not equally known to both parties, but where the opinion is expressed by the one party and is founded upon special skill or knowledge by which he alone is able to form an opinion.*

The expression of an opinion by a physician and surgeon relative to the subject of his profession comes peculiarly within the exception, and we therefore shall expect to see him held responsible for any deceit or misrepresentation. The case of Hedin vs. Minneapolis Medical and Surgical Institute† is one of some importance in which this question was adjudicated. In this case the plaintiff, an illiterate man, who had been badly injured in an accident, was suffering from a fracture at the base of the skull and was physically a wreck. He consulted the defendant. After being examined, he was positively assured by the surgeon that he could be cured by receiving treatment at that institute, but that he must pay a fee of five hundred dollars. By virtue of these representations the plaintiff paid the money demanded and submitted to the treatment, but upon failing to receive benefit therefrom, he brought suit to recover the money paid to defendant, basing his action upon the deceitful misrepresentation of the defendant's surgeon. The jury rendered a verdict of five hundred dollars in favor of plaintiff, from which defendant appealed, but the supreme court affirmed the judgment. Justice Collins, who gave the opinion of the court, expressed himself upon the law applicable to the case as follows: "Considering the circumstances and relations of the parties, there was something more in the defendant's statements than the mere expression of his opinion upon a matter of conjecture and uncertainty. It amounted to a representation that the plaintiff's physical condition was such as to insure a complete recovery. The doctor, especially trained in the art of healing, having superior learning and knowledge, assured plaintiff that he could be restored to health. That the plaintiff believed him is easily imagined, for a much stronger and more learned man would have readily believed the same thing. The doctor with his skill and ability should be able to approximate to the truth when giving his opinion as to what can be done with injuries of one year's standing, and he should always be able to speak with certainty before he undertakes to assert positively that a cure can be effected. If he can not speak with certainty, let him express a doubt. If he speaks without any knowledge of the truth or falsity of a statement that he can cure, and does not believe the statement true, or if he has no knowledge of the truth or falsity of such a statement, but represents it as true of his own knowledge, it is to be inferred that he intends to deceive. The deception being designed in either case, and injury having followed from reliance upon the statements, an action for deceit will lie."

Contributory Negligence.—In the eighth article of this series it has been observed that it is the duty of the patient to follow all reasonable directions and instruc-

*Rooz vs. Roecker, 52 N. J. L., 53.
†Hedin vs. Minneapolis Medical and Surgical Institute, 62 Minn., 146, 64 N. W. Rep., 158, 35 L. R. A., 417.

The instructions of the physician, in order to be binding upon the patient, must be such reasonable and proper instructions as a physician of ordinary skill would give; if, however, they impose unnecessary burdens or suffering upon him, he will be legally justified in not regarding them. In the case of McCandless vs. McWha,* the patient was suffering from a comminuted, oblique fracture of bothibia and fibula. The defendant attempted to effect extension and counter-extension by binding splints on the fore and back part of the leg, reaching from the ankle to the knee. These splints were bound on in such a way as to impede circulation, and to irritate the parts and cause them to be considerably swollen, thereby causing much pain. The patient, unable to stand the pain, loosened the bandages. This act, the defendant claimed, contributed to the injury, and should therefore be a defense to the action, but the court thought not. Justice Lewis said: "A patient is bound to submit to such treatment as his surgeon prescribes, provided the treatment be such as a surgeon of ordinary skill would adopt or sanction. But if it be painful, injurious, and unskilful, he is not bound to peril his health, and perhaps his life, by submission to it. It follows that before the surgeon can shift the responsibility from himself to the patient, on the ground that the latter did not submit to the course recommended, it must be shown that the prescriptions were proper, and adapted to the end in view."

If, however, the instructions given the patient were proper and adapted to the end in view, although the physician's treatment of the case may have been improper, and the patient fails to follow the instructions and injury ensues, what effect will such failure have upon his right to recover from the physician for the injury sustained? A casual examination of the cases in which this question is treated leads one to believe that there is considerable conflict of authority, but a more critical scrutiny shows that the conflict is only apparent, and that it results from a confusion of the two classes into which acts of this sort as a defense are divided.

The true doctrine, in general terms, seems to be that the physician having been guilty of negligence in the treatment of the case, the contributory negligence of the patient, when contemporaneous with the physician's negligence, or when uniting or cooperating with it in such a way as to conducive to the deleterious result of the physician's treatment, may be pleaded as a complete defense to an action against such physician. But if the contributory negligence is subsequent in point of time to the negligence of the physician, or if the effect of the latter is to the advantage of the physician and that of the patient can be separated in such a way as to show distinctly the deleterious result of each, then the patient's negligence will be received as a defense only in the way of

*McCandless vs. McWha, 22 Pa. St., 261.
mitigation of damages.* The case of Du Bois vs. Decker † affords an excellent illustration of the application of the second rule. The patient had through the improper treatment of the physician been subjected to two amputations. The physician set up as a defense that after the second amputation the patient failed to keep the limb in the position in which it was placed and in which he was instructed to keep it, and thereby produced bleeding which to some extent impeded the healing; also that he refused to take the doctor’s prescriptions about this time; and, further, that he left the hospital before he should have done so, which may also have aggravated the injury. This, the court held, was all proper evidence to be considered by the jury for the purpose of mitigating damages, but that it would not relieve the physician from the consequences of previous neglect or unskilful treatment.

In the case of Sanderson vs. Holland,‡ the patient, a little girl of six years, had fractured her arm at a point about two inches above the elbow. The physician, in reducing the fracture, first extended the arm its full length in a straight line, and in that position bandaged it from fingers to shoulder. He then put on splints from the shoulder to the elbow, and then forced the arm into a right angle so as to swing it, thereby pressing the elbow ends of the splints into the forearm, causing the child to scream with pain, and stopping the circulation of the lower arm, which caused gangrene. Permanent injuries ensued for which suit was brought. Evidence was shown by the defendant of careless treatment of the patient by her parents and others which contributed to the injury. In regard to the effect of this evidence Justice Gill said: “If the defendant carelessly and unskilfully set, bandaged, and dressed the plaintiff’s arm, and she was injured thereby, then the action will not be defeated by showing that subsequently her parents added to the extent of such injuries by their carelessness and negligence in nursing. This showing would not defeat plaintiff’s case, but merely go to mitigate the damages as against the defendant.”

On the other hand, the case of Young vs. Mason § illustrates the rule that where the negligence of the physician is either contemporaneous with that of the physician or contributes to the deleterious results of the original unskilful treatment of the physician in such a way that the result of the doctor’s negligence and that of the patient cannot be distinguished, then the contributory negligence is a complete defense to the action.

The patient had fractured the radius of her left forearm near the wrist, dislocated laterally both bones at the elbow, and fractured the inner condyle of the humerus.

The evidence showed that with one exception the physician dressed and treated the patient’s injuries in a manner approved and followed by the most skilled surgeons in that vicinity, and which is approved by the standard authors and text writers upon the subject of surgery. The exception is that the evidence did not conclusively show that he used proper skill and care in reducing the fracture near the wrist joint. The evidence also showed that the patient, contrary to instructions, removed her arm from the sling numerous times, placing it in different positions while out of the sling, and that the effect of removing the arm from the sling was to aggravate the inflammation and swelling, which had a tendency to produce the stiff and useless condition of the arm for which suit was brought. The evidence also showed that the proper treatment of the arm for the stiffness of the elbow, wrist, and finger joints was passive motion; that the physician endeavored to apply this treatment at the proper time but was prevented from so doing by the patient.

The court was of the opinion that the negligence of the physician alone was not the cause of the injuries sustained, but that that of the patient entered into the general result in such a way as to make the result of each indistinguishable; therefore the negligence of the patient was a complete defense to the action against the physician. Justice Davis, in rendering the opinion of the court, said: “For instance, suppose a man fractures the bones in his leg below the knee, and calls a surgeon to treat the injuries, and the surgeon negligently fails to reduce one of the fractures, but in all other respects gives proper treatment, and the patient, in disobedience to the directions of the surgeon, negligently removes the bandages used as a part of the proper treatment by the surgeon, or is otherwise guilty of contributory negligence, and such combined negligence of the surgeon and patient unite in producing a shortness and stiffness of the leg, for which injuries an action is brought against the surgeon—that can the patient recover? The patient is certainly not responsible in such a case for the original negligence of the surgeon in failing to properly reduce the fracture, but this negligence of the surgeon unites with the subsequent contributory negligence of the patient in causing the shortness and stiffness of the leg.” This being the case, a cause of action does not exist against the physician.

An instructive case comes to us from a Massachusetts report of some years ago. The plaintiff complained that through the negligence of the physician he became afflicted with a bedsore, from which by reason of negligent treatment he suffered damages. The evidence tended to show that the injury complained of was not a bedsore, but was caused by the patient’s attendants carelessly dropping him on the bed rail. There was evidence, however, which showed that the physician did not give the injury proper treatment and that it was thereby greatly aggravated. The instruction given to the jury by the court learnedly and clearly presents all the law of contributory negligence relative to the case, and is therefore quoted at length: “The burden of proof is on the plaintiff to show that all the injury for which he seeks damages proceeds solely from the want of ordinary skill and care on the part of the defendant. If it be impossible to separate the injury occasioned by the neglect of the plaintiff himself from that occasioned from the neglect of the defendant, the plaintiff can not recover. If, however, they can be separated, for such injury as the plaintiff may show thus proceeded from the want of ordinary skill or ordinary care of the defendant he may recover. In the present case the plaintiff claims damages of the defendant for want of ordinary care and ordinary skill in the treatment of him by the defendant, by which, as he says, first a bedsore was caused, and second, after the bedsore was caused, it was improperly treated and neglected. If the plaintiff shall fail to sustain you that the sore was caused by neglect of the defendant, for this damage he could not, of course, recover, but he might still recover
for the injury occasioned to him solely by the subsequent neglect of the defendant in not taking proper care of it (should he prove such neglect), even if the sore was occasioned by the plaintiff's own carelessness. If, however, in the case last supposed, the injury has resulted to the plaintiff not solely from neglect in the subsequent treatment of it by the defendant, but also from his own subsequent neglect, and the jury are not satisfied but that both causes have combined to produce the subsequent injury, the plaintiff can not recover for it. While, on the one hand, the defendant would not be released from his duty to exercise ordinary care and ordinary skill in his subsequent treatment of a disease because at a previous stage of it the plaintiff had himself been negligent, and had thus contributed to the condition in which he was, on the other hand it would be for the plaintiff to show, if he seeks damages for want of ordinary care and ordinary skill on the part of the defendant in his subsequent treatment, that it proceeded solely from this, and not from any subsequent neglect of his own.”

The defense of contributory negligence is one which may be made in many cases; it is therefore thought that the importance of the subject will justify the particularity with which it has been treated.

Survival of Action.—At common law a cause of action arising from an injury to the person caused by want of skill or negligence of a physician and surgeon did not survive the death of either physician or patient. The law upon this question has, however, been greatly altered in many of the States by statutes expressly providing for its survival, so that in case of death of either party suit may now be brought, or, if previously commenced, may be continued by or against the personal representative of the deceased.

(Tob to continued.)

Pith of Current Literature.

A Roomy Nasopharynx in Relation to Nasopharyngeal Troubles.—Mr. Lennox Browne's statement in his Treatise on Diseases of the Throat that "the wider the distance between the soft palate and the pharynx, the more surely one may expect to find postnasal trouble," having been taken exception to by a recent reviewer, Mr. Browne (Scalpel, July) reviews his position not only in the light of his own observations, but in that also of those of many of his colleagues, a large number of whom are in accord with him. Mr. Browne quotes the following words from an abstract in the Journal of Laryngology for March of a report of Dr. Gerber's Poliklinik for Nose, Throat, and Ear Diseases in Kopenhagen for the five years ending 1896 (Monatschrift für Ohrenheilkunde, July, 1898) on the etiology of ozena: "The nasal cavity is broader and shallower, the septum is shorter from before backward, and the depth of the nasopharynx is increased. Measurements in one hundred cases showed that in ozena the septum was shorter from before backward by three millimeters, while the diameter of the nasopharynx in the same direction was correspondingly increased."

Upon this Mr. Browne remarks that these words are pregnant with importance, and go far to confirm another of his contentions, that in the very large proportion of cases of so-called atrophic rhinitis, especially such as may be due to hereditary syphilis, scrofula, or struma, it is a misnomer to apply the term atrophy to a structure which has never been satisfactorily developed. He has explained this as due to "a want of correlation between the growth of the child and of the ethmoid structures. For this condition Wyatt Wingrove offers the alternative term 'dystrophic.' Mr. Browne has also alluded to the converse circumstance, "that we have a so-called hypertrophy of the nasal structures of children occurring before puberty, in which the growth of the turbinal is in excess of the growth of the child."

Gerber's figures and facts would appear to show that what Mr. Browne has suggested as the result of postnatal irregularity of growth has really commenced as an incident of embryonic life, and he accepts and desires to adopt the correction.

Gerber's information is further interesting as affording confirmation of the view that what Mr. Browne has described as the facial type in atrophic rhinitis is equally due to embryological vice, seeing that both are in all probability equally dependent on imperfect development of various and allied rudimentary processes, each springing from one and the same source. This facial type consists of "an abnormal patency of the anterior nares, with an upturned condition of the nose. This excessive patency and 'tip-tilting' of the nostril is not dependent on any (postnatal) morbid process in the septum, as is seen in ulcerative syphilitic diseases, but is a congenital feature which presents an aberrant type in the frontal-nasal plate. Thus, the anterior aperture of the nostril, instead of looking almost directly downward, looks more or less forward, and so allows the air current to pass directly into the inferior meatus." In his opinion the pathological effect of this perverse arrangement is accounted for by the circumstance that this direct intake of the breath is favored by the greater width of the nostrils, and by the absence of the vibrissae, which in itself constitutes an early evidence of the atrophic process. The air, therefore, passes straight through the inferior meatus to the pharynx, instead of traversing the middle and (already roomy) superior parts of the nasal cavities; as a consequence there is insufficient diffusion with the warmed and moistened air of the nasal fossae, and of the accessory sinuses— the nasal reservoirs.

To summarize— atrophic rhinitis, which, be it noted, is essentially both a nasal and a nasopharyngeal disease, is associated with undue patency of nasal orifice, nasal vestibule, nasal fossae, and of nasopharyngeal vault. It may be taken therefore as a type of what is likely to be found in "the happy possessor of a roomy nasopharynx."

The Destruction of the Femoral Artery and Vein without Loss of the Limb.—Dr. B. Merrill Ricketts (Journal of the American Medical Association, August 12th), in a paper on this subject presented to the American Medical Association at Columbus, reports three of his own cases in which respectively the femoral vein, the external iliac vein, and both the femoral artery and vein were ligated without occlusion and with restoration of the limb. The author draws the following conclusions: 1. Amputation of the leg is not
always necessary when the lumen of the femoral artery or vein, or both, is suddenly or slowly occluded by injury or otherwise. 2. It is better to ligate the femoral artery or vein, or both, and give the patient the benefit of a doubt than to amputate immediately. 3. It is impossible to determine the circulation of the thigh or any given part of the human body without a complete dissection, which can only be done post mortem. 4. Ligating the femoral artery or vein, or both, in chronic pathologic conditions of the thigh, seems less likely to result in death or gangrene than when the ligature is applied in case of accidents in a normal thigh. 5. It cannot be determined what rôle, if any, one of the six varieties of the femoral artery has played in any case in which the femoral artery or vein, or both, have been ligated, as no record of dissection seems to have been made. 6. While end-to-end anastomosis may be accomplished, complete occlusion sooner or later takes place. 7. Suturing and the application of ligatures to arteries and veins which have been lacerated have no advantage over complete immediate occlusion by ligature. 8. Gangrene is possibly due to septic infection and not merely to the occlusion of the femoral artery or vein, or both, unless the vessels for collateral circulation are absent. 9. The preservation of the leg does not seem to depend upon the ligating of the femoral artery or vein, or both, at any particular point.

**Five Cases of Angina caused by Pneumococci** were observed by A. and V. Vedel (Montpiller medical, 1898, No. 29; Pediatircs, August 15th). Three cases represented the erythematous form, and the patients recovered in from seven to eight days. Two exhibited a pseudo-membranous angina; these patients gave the impression from the beginning of suffering from a severe infection. All therapeutic resources (including antitoxine) were useless, the cases ending fatally.

**The Importance of the Diazio Reaction in the Diagnosis and Prognosis of Scarletina and Measles.**—Lowé (Bolnitzcha Gaoeta Botkina, No. 2 to 4, 1899; Clinica moderna, July 26th) has instituted careful researches in nine hundred cases of scarlet fever and measles, and has come to the conclusion that the diazio reaction does not constitute a pathognomonic sign of any malady, but is solely an indication of the gravity of the case.

**The Operative Treatment of Labor in Cases of Pelvic Deformity.**—Dr. George W. Dobbin (Obstetrics, Augst), from a critical review of the first thousand patients delivered in the obstetrical department of the Johns Hopkins Hospital, concludes that: 1. In a hundred and thirty-one cases of contracted pelvis there was necessity for operative delivery forty-six times, or 35.11 per cent. 2. The pelvis most frequently requiring operation are the rheumatic and irregular forms. The generally contracted pelvis, though very common in the negro race, is comparatively rarely sufficiently deformed to seriously obstruct labor. 3. Pelvis in which the degree of contraction is slight, and those in which the contraction is very marked, are the easiest for treatment, as in both cases the indications are definite, and should give the operator little trouble in deciding upon the treatment to be pursued. 4. On the other hand, the pelvis possessing a medium degree of contraction are the most perplexing, and call for the exercise of the greater skill and judgment. When proper appliances are at hand, such cases are best treated by tentative application of forceps, and this failing, immediate Casarea section. 5. In general, forceps give a lower fetal mortality than version, but version done as a primary operation on a movable head in a slightly contracted pelvis is a safer operation for the child than a difficult high forceps operation. 6. Except in very exceptional cases, symphysiotomy is not to be compared with Casarea section, for the former operation, besides causing greater injury to the mother, is always an uncertain procedure. 7. Operations on contracted pelvis are rarely uncomplicated. Among the commonest accidents may be mentioned premature rupture of the membranes and prolapse of the umbilical cord. 8. The only rational and scientific method of obtaining "corrected morbidity" statistics is by the bacteriological examination of the uterine lochia, for only in this way can we say definitely which infections are the result of operation.

**An Ovarian Cystoma One Hundred and Seventy-six Pounds in Weight.**—Dr. D. Tod Gilliam (Medical Record, August 5th) thus describes an enormous tumor operated upon by him: "I was brought into the presence of the patient, and must confess that I was surprised and disconcerted. As she lay in bed on her side with her back to the wall the tumor filled the bed, and as it quivered and vibrated with the respiratory movements it presented a spectacle that I shall never forget. It was simply monstrous, uncanny, and inhuman. In its huge and tremulous expansive it reminded one of a mastodonic amniotic sac. A peculiar feature was the comparative laxity of the cyst and abdominal walls, which allowed it to flatten out and spread all over the bed, and it extended from high up on the chest to below the knees. The face, chest, and arms were emaciated to the last degree, while the lower half of the abdomen was knobby and indurated as in elephantiasis. The lower extremities were truly elephantine in shape and appearance. I could not see the genitalia, nor did I make any attempt toward a vaginal examination, as these parts were obviously inaccessible. She was examined lying on her side, as the pressure of the tumor on the diaphragm gave rise to suffocative symptoms. The perussion wave was strikingly distinct over all parts. She was helpless in bed, and it required the assistance of several persons to change her position. Nevertheless, if placed on her feet she could walk. On the day of her admission, in attempting to change her position in bed the tumor gave a lurch and carried her bodily to the floor. It required the combined efforts of several men and nurses to replace her in bed. She was tall and of large frame, but with the exception of the lower extremities had wasted to a skeleton. She was of buoyant disposition and rather inclined to be jovial. I found her to be a woman of more than ordinary intelligence and shrewdness."

The author then describes the operation as follows: "The patient was in the best of spirits. She took the ether nicely and was placed on the operating table on her side. The bulk of the tumor extended over the side of the table and had to be supported by an assistant. This assistant was relieved at short intervals, as the position was too irk-some to be maintained for any length of time. An incision six inches long was made down to the sac and revealed the thickened abdominal walls, consisting entirely of hyperplastic connective tissue. The eyst wall was also thick and dense, and was with difficulty penetrated by the trocar, showing that the abdominal and cyst walls had grown pari passu with
the cystic accumulation, and that neither suffered from the pressure atrophy usually found in such cases. A large washtub was placed to receive the contents, which were of the color and consistence of very muddy water. The fluid left a greenish-yellow deposit on anything with which it came in contact. When the tub was nearly full it was removed and a waste-water tub substituted. It required three of these, besides the large washtub to receive the contents. These tubs were all removed to one side of the room that no extraneous matter might find its way into them. The patient was now placed on her back and an attempt was made to break up the adhesions between the cyst wall and abdominal parietes, in which great difficulty was experienced. The pedicle was broad and was secured by a circumferential stitch. The cyst was cut loose and dropped into a receptacle. On attempting to wash out the cavity the two gallons of water poured in disappeared as completely as though poured into a waste-pipe, and it was seen that nothing short of a tub of water would avail to flush the cavity, so the attempt was abandoned. The redundant tissues of the abdominal wall hung down on either side of the table and covered the thighs to the knees. The surface was thrown into innumerable folds and fissures, but the folds were much longer and the wrinkling less conspicuous than in other large abdominal growths, because of the unusual thickness of the parietes. In attempting to sponge out the cavity pools of fluid were found in all sorts of out-of-the-way places. At this juncture what appeared to be a segment of the cyst wall about the size of a man's hand was found situated over the bladder and so firmly attached as to preclude any attempt at separation. The margins were clean cut as if severed by the knife or scissors. No one had any recollection of aught but the pedicle being severed, and the discovery of this gave rise to no little thought and speculation. After careful sponging and drying, the patch was folded on itself longitudinally and the edges were stitched with the Lambert suture. The wound was then closed, but in applying the bandage a large pendulous mass extended down over the thighs. The fluid contents of the tumor were next measured, a quart measure being used for the purpose. This was done by a sister supervised by the chief nurse. The count was made aloud and repeated by two censors and witnessed by several bystanders. There was no chance for deception or mistake. A quart of the fluid exclusive of the vessel was found to weigh two pounds and a quarter almost precisely. Of this fluid there were seventy-five quarts and a fraction. The cyst wall with its residue weighed a few ounces less than seven pounds. Altogether, therefore, the tumor weighed a little more than one hundred and seventy-six pounds. The patient did well from the first, although the pulse rate continued at or about 100 for two weeks. The only trouble arose from the maceration and excoriation of the skin in the deep sulci between the contiguous folds, necessitating the use of cotton packing as a protective.

An Operation for Restoration of the Lower Lip after its Entire Removal for Cancer.—Dr. Frederick Winnett (Canadian Journal of Medicine and Surgery, August) describes a case in which he recently modified the method of Regnier, which is simple of execution, and renders gangrene impossible, and the cosmetic effect perfect. Four years and a half ago a warty growth appeared, which two years and a half later became cancers, and was removed by a quack with plasters. A year later it returned and was treated in a similar manner. The present growth began the previous August. Glands could not be felt.

With scissors the part was freely removed, the cut extending in a curved direction from the angles of the mouth to within three quarters of an inch of the lower margin of the chin. Two inches below this wound a parallel incision was made five inches in length through the skin down to the periosteum, and the bridge of skin was freed. A second bridge of skin was raised below this, an inch wide and two inches in length. Several enlarged submental glands were removed. The upper bridge of skin was slid up in contact with the upper lip, and anchored to the periosteum with four silk wound sutures passing through the skin. The lower incision was sutured, bringing its ends together, thus causing it to assume a vertical direction, and forcing the lower bridge of skin up to cover the entire wound left by the removal of the upper bridge. The patient returned to business in three weeks.

The author's method differs from Regnier's in two particulars. The directions given by Regnier for estimating the width of the bridge of skin—one centimetre wider than the part to be removed—would often leave the cicatrix visible on the chin. The average width of the skin from the margin of the lip to the border of the chin is two inches. The author would therefore recommend that the bridge be always two inches wide in order to cover the whole chin and bring the cicatrix below it.

In the second place, the leaving of the raw surface to granulate is most objectionable, not only on account of prolonging convalescence and leaving a scar, but also on account of ultimate contraction drawing the lip down. Grafting would probably fail, owing to the discharges, and in a man would leave a bald spot. The author's plan utilizes the loose skin of the neck, leaving no part uncovered and hastening recovery.

AMERICAN LARYNGOLOGICAL ASSOCIATION.

Twenty-first Annual Congress, held in Chicago, Monday, Tuesday, and Wednesday, May 22, 23, and 24, 1889.

The President, Dr. William E. Casselberry, of Chicago, in the Chair.

Adeno-carcinoma of the Nose, with a Report of a Case.—Dr. James E. Newcomb read a paper on this subject. (See page 366.)

Dr. G. V. Woollen, of Indianapolis: I wish to briefly narrate a case that came under my observation last winter. I feel a little embarrassed in speaking of it because of failure of the microscope to determine the true condition. In this case nasal polypi had been removed by a rhinologist a number of times. The child was only eight years of age. The physician was apparently competent to determine that the growths he removed were polypi. In the mean time an effort had been made by a competent microscopist to determine whether the disease was malignant or not, and he declared it was benign, and that the disease was mucoid in
character. I was impressed with the malignant appearance of the patient when brought to me. There was some exophthalmia, with deep ethmoidal trouble, cataract, and possible sepsis. The masses in the posterior naris were finally removed after proper preparatory treatment. I saved a specimen for microscopical examination, but on account of a mistake of my assistant it was lost. The disease recurred rapidly after this. The masses and surrounding tissues were again removed with snare, curette, and scissors from the naris and nasopharynx very thoroughly, provided it was superficial in character. Again the disease recurred, and hemorrhage supervened to such a degree that I determined not to do a further operation. The child was so exhausted and so young that after consulting with a competent surgeon I decided not to attempt to remove the superior maxillary. The parents were not satisfied with my decision, and I was pleased to refer the case to Dr. Solis-Cohen, of Philadelphia, who confirmed my diagnosis, as also my opinion as to the undesirability of operating again. The patient subsequently died from enormous distention of that side of the face; exophthalmia was marked, and the case proved to be malignant, without doubt, although not confirmed by the microscope. The reason why I speak of this case is: First, the appearance of this disease at so early an age. Second, the microscopist reporting that it was mucoid in character. However, I am anticipating myself a little. Two years ago the patient fell and received a severe injury of the bridge of the nose, so that traumatism seemed to be the initial influence in the production of the disease. Mucous polypi, apparently, were the first manifestations of the disease, and some of the masses I removed were so distinctly polypoid in character that I could not be mistaken. What the ultimate analysis would have shown with the microscope I could not say, but it was probably an adeno-sarcoma. The points of interest in the case are its traumatic origin, the youthfulness of the patient, the mixed character of the growths, and the possibility that surgical interference aggravated the disease.

Dr. E. Fletcher Ingals, of Chicago: I was surprised at the small number of malignant tumors of the nose mentioned by the author. I might have reported half a dozen, if I had thought them of special interest. So far as the macroscopical appearances and clinical histories could determine I have reason to suppose they are not very infrequent. I have had microscopical examinations made in but one case, and in this the findings were not typical, though the examination was made by an expert, but the clinical history justified the diagnosis very promptly.

Dr. J. L. Goodale, of Boston: In the discussion of Dr. Newcomb's paper I wish to mention briefly a case which I have had under my care since last year of epithelionoma of the ethmoid region in a man, fifty-one years of age, who had polypi for over twenty years. These were removed semiannually by one or more physicians. He came to me in May, 1898, with a history to this effect, that during the preceding five months he had a bulging left eye, which was attended with great pain in the ethmoidal region, and blocking the nose much more so than it had done for some time previously. I found the left nostril completely filled with a friable, easily bleeding mass, a portion of which was removed, and showed on microscopical examination a connective-tissue stroma containing nests of epithelial cells. During the next five months I removed a large amount of similar tissue. Recurrence was rapid, and the man died a few months ago.

Dr. Thomas Hubbard, of Toledo: I wish to place on record the case of a farmer in whom the cause of the disease was a suppuration of the antrum. Syringing was carried on by the patient for a period of seven years, resulting in the formation of a growth undoubtedly within the antrum. When I saw the man the whole naris was filled with a mass of what I believed to be carcinomatous tissue, and my diagnosis of adeno-carcinoma was confirmed by an expert microscopist. While this may be classed as a carcinoma of the antrum, yet the fact is that the growth probably originated near the ostium maxillare and developed simultaneously in the nose and in the antrum.

Dr. B. Braden Kyle, of Philadelphia: I desire to say a word or two in defense of the microscope and of the microscopist. The specimens of tissue taken from the nasal mucous membrane in cases of tumors are not sufficiently large to enable the microscopist to make a positive diagnosis. In a number of instances in which I have examined small specimens, I have sent a report back to the effect that the piece of tissue was not sufficiently large to make a microscopic diagnosis. You know that the mucous membrane of itself is a one-sided affair, backed up by bony structure, and a microscopist can not arrive at a positive diagnosis as to the malignancy or benignity of a tumor when such a small section is sent to him for microscopic examination. In all of these cases physicians should see to it that they remove larger pieces of tissue by going down deeper into the structure. Frequently the specimens are not large enough to warrant any one in making an accurate diagnosis. The microscopic examination should always be associated with the clinical history.

Dr. Newcomb: I have only a word or two to add. I was interested in the case related by Dr. Woollen, in view of the early age at which the polypus manifested itself in this child. Personally, I have never seen a polyp in a child under eleven.

In regard to the interesting and instructive case of Dr. Hubbard of an adeno-carcinoma starting from the antrum, I have endeavored in this collation of cases to limit myself strictly to malignant tumors of the nares. There are one or two cases of carcinoma reported as having started from the antrum, then running outside, one case through a tooth socket, and in one or two other instances spreading inward through the nasal fossa. I purposely omitted those cases from the category.

I am not a microscopist in the technical sense of the term, although I agree to what Dr. Kyle has said in reference to the importance of furnishing larger pieces or sections of tumors to the microscopist to enable him to confirm the diagnosis. Furthermore, I think we should furnish the microscopist with specimens removed at different times, particularly when we have reason to believe that we have to deal with a new growth. There is a good deal we do not know with reference to the change in the characteristics of new growths. These changes are as obscure to the microscopist as they are to the clinician.

Presentation of New Instruments.—At the end of the association's meeting the following new instruments were presented. Their description is included in the current number under the head of New Inventions.

An Adjustable Nasal Splint.—Dr. John W. Farlow presented a nasal splint devised by Dr. R. A. Coflin, of Boston. (See page 392.)
Three Improved Instruments for Use in the Operation for Removal of Lymphoid Growths from the Vault of the Pharynx.—These instruments were presented by Dr. Thomas R. French. (See page 393.)

(To be continued.)

Book Notices.

To make a correct diagnosis in all forms of fractures and dislocations and to follow it with the proper treatment, requires a vast amount of clinical experience, which, unfortunately, can not be obtained by all of us. Wading through countless pages of descriptive matter to obtain the desired information is both irksome and unsatisfactory. This atlas is therefore a boon to the student, for in a measure it supplies him with the needed clinical material, and at a glance he sees the injury portrayed before him, together with its anatomical features. We can hardly say as much for the treatment advised, which, although rational in character, is necessarily briefly treated, owing to the limited space available in so small a volume.

The atlas is therefore 130 pages, mostly devoted to the description of the colored plates, which are not only beautifully executed, but show a vast amount of careful preparation. Especially is this the case in regard to the dissections of artificially produced fractures and dislocations, to show the pathological anatomy thereof. Some of the figures are taken from photographs and reproduce the deformities existing in the living subject. These are especially interesting and instructive. Museum specimens and the cadaver have been called upon where clinical material has been lacking.

The atlas has supplied us with a long-felt want.

The addition of several illustrations is the only prominent feature that differentiates the latest edition of this admirable work from its immediate predecessor. This is accounted for by the very brief time that has elapsed between the publication of the two editions, a brevity which must of necessity be flattering in the extreme to the author.

The sixth edition of this work, following so closely upon the last, evinces a growing popularity for this little book, which is intended solely for the use of mothers and nurses. It has been carefully revised and much of interest added to the text.

BOOKS, ETC., RECEIVED.

Transactions of the Medical Society of the State of New York. For the Year 1899. Thirty-ninth Annual Report of the Medical Superintendent of the Matteawan State Hospital. For the Year ending September 30, 1898.

Rectal Carcinoma with Subsequent Colotomy. By B. Merrill Ricketts, M. D. [Reprinted from the Philadelphia Medical Journal.]

Craniat Injuries of Childhood and their Treatment. By B. Merrill Ricketts, M. D. [Reprinted from the Virginia Medical Semi-Monthly.]

The Evolution of Modern Therapy. An Address read before the Society of the Alumni of the Medical College of Virginia. By Simon Baruch, M. D. [Reprinted from the Therapeutic Gazette.]

New Inventions, etc.

AN ADJUSTABLE NASAL SPLINT.*

By John W. Farlow, M. D., Boston.

Dr. Farlow: I would like to present an adjustable nasal splint devised by Dr. R. A. Coffin, of Boston, and made by Codman & Shurtleff. As the illustration shows, it consists of two nearly flat pieces of perforated silver, between which is an oval spring of composite metal, which has running through it a small rod, headed at one end, and having a thread and nut at the other. By turning the nut with the key the blades of the splint may be separated to any desired width.

As advantages over the ordinary hard-rubber splint may be mentioned: First, the blades may be very closely approximated, thus allowing it to be introduced with ease; second, it may then be adjusted to any width; third, the patient can breathe easily through it and also irrigate the nostril; fourth, the even pressure of

* Presented at the twenty-first annual congress of the American Laryngological Association.
the flat blade against the septum makes perforation less likely, and the septum unites smoothly and in a vertical position; fifth, in case it is necessary to fracture the maxillary ridge, the splint holds it well in place, as the blades come well down on the floor of the nose.

The patients on whom Dr. Coffin has used it all agree that the air passes freely through the splint while in place. The fact that the blades are expanded by an oval spring allows it to adapt itself more to the lateral wall, thus making it more comfortable to the patient. For cleaning after removal, it can be placed in boiling water and afterward in peroxide of hydrogen.

THREE IMPROVED INSTRUMENTS FOR USE IN THE OPERATION FOR THE REMOVAL OF LYMPHOID GROWTHS FROM THE VAULT OF THE PHARYNX.*

By Thomas R. French, M.D.

These three instruments, which I take pleasure in presenting to the association, have recently been evolved from the cutting forceps and mouth gag which I designed a number of years ago for use in the operation for removal of lymphoid growths from the pharyngeal vault. The bite of the cutting end of the forceps has been gradually extended until, as used at present, the blades embrace, practically, the entire length of growths in the pharynges of children (Fig. 1).

The forceps is made heavier than the original instrument. The fenestrae are larger, and therefore the curve of the distal end is greater. The plates forming the back of the oval rings are widely separated, so that a large part of the growth can be grasped and held while the cutting edges are dividing the growth at its base. The bulk of the lymphoid mass is removed with the first cut, and that which remains attached to the posterior wall can be readily and rapidly removed with a few bites of the forceps. While the cutting blades are made broad to give them strength, I have but rarely been obliged to use smaller forceps to eradicate the tissue lying behind the Eustachian eminences. The curve of the cutting edges seems to be well adapted to the curve of the posterior wall and vault in most children's heads, and the cut surface is left clean and smooth. The vault is usually completely cleared while the growth attached to the posterior wall is being removed, but occasionally a few taglike bits of tissue are left, which can be quickly and certainly removed by means of the second forceps (Fig. 2).

This forceps is exactly the same as that which has just been described, except that the cutting edges are confined to the curve at the distal extremity of the instrument. With the child in the upright position so little bleeding occurs that even very large growths can be most thoroughly eradicated with this forceps, in practised hands, in from ten to fifteen minutes.

The mouth gag (Fig. 3) is made heavier than the original instrument to accommodate a strong ratchet catch, which holds the blades much more securely. The spread of the arms is great enough to permit of its use in adults. As all the parts in the new model are detachable the instrument can be made aseptic.

* Presented at the twenty-first annual congress of the American Laryngological Association.

A Modification of Bosworth's Nasal Speculum.—The modification consists, first, of a backward angular projection of the nasal blades, and second of the use of rings instead of discs for the grasp of the thumb and forefinger (Fig. 4). The object of the prolongation of the nasal blades is to secure a better expansion of the nostril and to prevent the heels of the blades from slipping into the nasal opening.

All the instruments described above are made by Fred. Haslam & Co., of Brooklyn.
The Term "Degenerate."—The London correspondent of the Medical News for August 5th writes the following pertinent comment on a recent sensational poisoning case in London: "Both the experts who examined Mary Ansell, hung last week for the poisoning of her sister, declared themselves unable to find any ground for regarding her as insane, and as against the statement of Dr. Nicolson and Dr. Brayn, both of Broadmoor Asylum, there is nothing to be placed except the moonings of that spectacular alienist, Forbes Winslow, who was sure she was a 'degenerate' without ever having examined her. Public opinion generally acknowledges the justice of the sentence. Almost the only exception is the well-meaning but unbalanced Daily Chronicle, which came out with an editorial shriek a column long, protesting in tones that remind us of our own transatlantic hysterics on the same subject, against the execution of any woman, for no matter what crime! 'Degenerate' is a very pretty term of such elastic application that it can be made to apply to almost any case, and like the bulk of the Lumbrosus-Nordau vernacular is of little more scientific value than 'crank.' Certainly it is utterly insufficient to place a plea of irresponsibility upon, in the case of a deliberate cold-blooded murder for a purely mercenary object. If this be 'degeneracy,' then it is an element which the law does well to insist in eliminating.

The Stemming of the Tide of Criminal Abortion.—Dr. Henry T. Byford (Western Medical Review, July 15th) refers to the two classes of women who approach the physician in the hope of having abortion procured—viz., the married and the unmarried. In the former class there can be but rare occasions when operation is justifiable, and these cases have been well defined, and the operation should never be undertaken save as the result of a consultation. Of the latter class the author says: "But the other far more interesting class of unmarried woman, with whom it is make or break, do or die, can not be disposed of in an off-hand manner. Those who have loved not wisely but too well, those who have been thoughtless and reckless because they were young and uninstructed, yet who have social relations that would make a disgraced life more unbearable than death, can not be dismissed with the words: 'You have done wrong and you must take your punishment. Do not expect another to kill the offspring of your sin for you.' She can not do this for herself, but she does expect some one to do it for her; and some one else usually does. How much shall we blame her? If she can not get rid of her disgrace, she may, if courageous, kill herself. How much shall we then blame her? The world does not blame men very much who have yielded to less temptation. She may not have an opportunity, nor the means, to go away and safely and secretly bear her child. Her life must be ruined or an abortion must be produced. She will go to a charlatan or the professional hypocrite, and will have a sound passed, and run considerable risk of life. I now remember two cases in which girls of good morals, if we except one lapse, died in their father's houses of septicaemia due to abortions produced at physicians' offices, in which cases the fathers knew nothing of the cause of the illness. I remember a hired girl brought to the hospital dying of septicaemia from abortion, because she had not dared to tell of her trouble and employ proper treatment. I was called to see a case at the house of an abortionist, in which I found the intestines hanging out of the vagina. At the post-mortem a catheter was found under the liver. The posterior wall of the uterus had been cutted nearly all away, and the intestines had been mistaken for femoral parts.

"Such deaths are constantly occurring in our larger cities and only one or two interested parties usually know the facts. Many a sterile wife is going about to-day because of pelvic disease caused by abortion before or after marriage. But when, after wasting much strength and valuable time in trying to arrange some way with such a patient of avoiding an abortion, and after preaching to her, frightening her, and refusing to help her get rid of her disgrace, I send her away, I feel as if something was wrong with myself or with the world, that her wrong could not in some way be righted, that she must go and put her life in the hands of a man who makes abortion a business because he has not the education and skill to make a living without becoming an abortionist.

"If public opinion can not be changed, if there is no way of infusing any mercy or tolerance into it, then public opinion should wear blue glasses that it may not distinguish all that is going on. One of the greatest possible charities would be endowed hospitals in various parts of the country where such cases could be secluded and their children be taken care of, that there might still be preserved to them a chance of enjoying life. I remember when one of our largest and best-known hospitals in Chicago, supported by a religious institution, refused to take illegitimate cases of labor. I sincerely hope that the ministers will have some helpful suggestions to give us who are the first to see such cases, and I sincerely wish that in imitation of Christ of the New Testament they would preach tolerance and mercy to this class, for I have found that they can not be influenced by fear, and can only be helped by mercy. They keep away from the clergyman, and he practically knows them not; they conceal themselves from the world, and the world regards them only as strangers, and smiles and gossips when it discovers one of them. If all cases were treated publicly, the conditions would be better than they are now, for not only would the victims be saved physically, but I imagine that so many families would have the record of a black sheep at some time or another that they would forgive others that they might themselves be forgiven.

Sanitary Education of the Public in Indiana.—The State board of health of Indiana has issued a very comprehensive circular concerning small-pox, dealing with vaccination, the diagnosis of the disease, and general directions for the management of small-pox cases, including isolation, care of the sick-room, disinfection, etc. Appended to the circular is the following:

"Address to the Public by the Indiana State Medical Society, upon the Prevention of Tuberculosis and Small-pox.—It has ever been the duty and the pride of the medical profession to try to protect the public against avoidable diseases, bodily injuries, and unsanitary methods and conditions of life. The physician has always been taught, and the true physician has always acted upon the conviction, that he was the guardian of the public health, and that his constant en-
deavor should be to prevent as well as to cure disease. The Indian State Medical Society, now gathered in its fiftieth annual meeting, having heretofore repeatedly, as the times seemed to indicate, exerted its influence to promote the public health, and being mindful of its continuing duty in this respect, feels called upon to address the public upon the prevention of two most serious diseases, small-pox and tuberculosis; the one, the pest of the last century but now happily avoidable by well-known means, the other the present but hopeless scourge of our race. The State Medical Society feels warranted and impelled to address to the public the following proposition concerning tuberculosis: 1. That tuberculosis is caused by certain known germs. 2. That while heredity may in many instances furnish a favorable soil for infection, in a large proportion of the cases the disease is acquired after birth. 3. That the germs are present and demonstrable in the products thrown off from the seat of disease in men and animals. 4. That these germs may, especially within doors, retain their life and virulence for a long time, being demonstrably capable of reproducing the disease. 5. That while in most cases it is impossible, on account of the insidious development of the disease, to demonstrate the exact time and place of infection, the fact of such infection is unquestionable. 6. That by proper and simple means, thoroughly carried out to prevent the scattering of these living germs from man and animals, the danger surrounding persons and animals so affected, and the spread of the disease to others, may in large measure be prevented. 7. That a rational manner of life, as regards the simple, fundamental factors of health and development—namely, food, rest, avoidance of nervous overstrain, and abundance of pure air, especially during childhood and youth—will do much to fortify the body against tubercular infection. 8. That the society does, upon the basis of these facts, invite and urge the public to join with the physicians and sanitary boards of the State in instituting and carrying out the rational measures having these happy ends in view.

Concerning small-pox, the committee says: 1. That the ordinary sanitary measures thoroughly applied, though of the highest value and by no means to be neglected, have nevertheless not proved sufficient to control the spread of small-pox. 2. That in vaccination and revaccination, accurately and thoroughly applied, there is an almost absolute preventive of small-pox. 3. That though with the lapse of years after successful vaccination the protective influence may decline and small-pox may be contracted, the disease is robbed of most of its dangers. 4. That properly applied, in the hands and throughout under the direction of competent physicians, vaccination is attended with but insignificant risks, the disease-preventing and death-preventing effects vastly outweighing such risks. 5. That upon the basis of these convictions the State Medical Society does invite and urge the public to a full confidence in the preventive value of vaccination against small-pox, and does urge the public to relax in no direction its vigilance in the carrying out of this disease-preventing and life-saving measure.

Death of Dr. Max Thorne.—The New York Times for August 28th announces that Dr. Max Thorne, of Cincinnati, was found dead in a bathroom on the 27th inst. Dr. Thorne held the chair of laryngology in the Cincinnati College of Medicine and Surgery. He was a fellow of the American Laryngological Association, of the American Laryngological, Rhinological, and Otological Society, and also of the Berlin Laryngological Society.

Execution by Suggestion.—The Indian Medical Record for July 26th is authority for the following: "Many years ago a celebrated physician, author of a work on the effects of imagination, wished to combine practice with theory in order to confirm the truth of his propositions. To this end he begged the minister of justice to allow him to try an experiment on a criminal condemned to death. The minister consented, and delivered to him an assassin of distinguished rank. The servant sought the culprit, and thus addressed him: 'Sir, several persons who are interested in your family have prevailed upon the judge not to require of you to mount the scaffold, and expose yourself to the gaze of the populace. He has, therefore, commuted your sentence, and sanctioned your being bled to death within the precincts of your prison. Your dissolution will be gradual and free from pain.' The criminal submitted to his fate, thought his family would be less disgraced, and considered it a favor not to be compelled to walk to the place of public execution.

"He was conducted to the appointed room, where every preparation had been made beforehand. His eyes were bandaged; he was strapped to a table; and at a preconcerted signal four of his veins were gently pricked with the point of a pen. At each corner of the table was a small fountain of water, so contrived as to flow gently into basins placed to receive it. The patient, believing that it was his own blood he heard flowing, gradually became weak, and the conversation of the doctors, carried on in an undertone, confirmed him in his opinion. They receded by degrees, and continued to lower their voices; and the stillness which reigned in the apartment, broken only by the dripping fountains, the sound of which was also gradually lessened, so affected the brain of the poor fellow that, although possessing a strong constitution, he fainted and died, without having lost a drop of blood."

Immoral Molluscs.—The British Medical Journal for August 12th actually devotes a leading article to The Abandoned Oysters Bill. We have heard of a man being described as a "loose fish"; but it is he who gives that nickname free with "abandoned oysters." Oysters, it is true, possess, by common repugnance, aphrodisiac properties, but that surely is an inadequate reason for stigmatizing them as "abandoned."

Somewhat Tardy!—According to the Medical News for August 6th, the Liverpool Samaritan Hospital for Women elected the late Lawson Tait consulting surgeon some time after that distinguished surgeon's death.

Why he had Three Lanterns.—The following story, which appears in Σοληνείς, a Greek journal published in Cyprus, has been sent to us: An embarrassing law in China forces every physician to hang out at his door at night as many lighted lanterns as he has sent unfortunate ones into the other world. One evening a European, a business man living in Peking, went out to summon a physician to attend his wife, who had been taken sick suddenly. He passed many physicians' houses, but found to enumerate many of these because they all had a large number of lanterns. Finally he came to one where only three lanterns cast their melancholy shine over the entrance. Our European thought him-
self fortunate, entered the house of this wise disciple of Asclepius, awoke him, and took him to his own house. While the two were walking along the merchant said, "I presume you are the best physician in this city?" "What makes you think so, sir?" "Because you have only three lanterns at your door, while all your colleagues have dozens of them." "Ah, this is the reason," answered calmly our unsophisticated Asclepius: "the truth is that only the day before yesterday I hung out my sign for the first time, and as yet I have only been called to attend three patients."

Professor Ogston's Address on Surgery.—Professor Ogston's practical support of those who declaim about the incapacity of the army doctors by a sort of apologetic "it isn't their fault, but the government's, which does not give such conditions as to attract the best men, or facilities for those who do enter to keep themselves up to the mark," draws forth in the British Medical Journal for August 19th the following energetic protest (much of which has a bearing on army medical officers in this country) from a correspondent signing himself "Zoji La":

"As a member present at the meeting in Portsmouth and on again reading Professor Ogston's address, I, in common with many others, consider it very uncalled for and most inopportune. It bristles with errors and inaccuracies strange, indeed, in one in the position of an Aberdeen professor. According to him, so unpopular have the naval and military services become that for the past three decades only men of inferior qualifications have been induced to present themselves for examination; this is utterly untrue, unless the professor is prepared to admit that degrees in arts and medicine of the universities of England, Scotland, and Ireland, diplomas of the several colleges, including fellowships, can be classed as inferior qualifications. He states that after a few years' experience of the services men who enter admit that they have made a mistake and would gladly go if they could; this is sheer nonsense. Why don't they go? Why not sacrifice a few years for 'a comparatively unpromising post in civil life'? Even, according to him, if they do leave the service in the 'prime of their abilities,' all except a gifted few are found to have so degenerated as to be utterly unfit to compete with their civil compatriots; the professor may be assured that these compatriots find retired army medical officers when he competes against them not so dormant as he imagines! He would also have the public believe that the army medical officer is only called upon to treat minor ailments. A more erroneous statement could hardly be made; he seems unaware of the fact that at Portsmouth and many other military stations special hospitals exist for the treatment of the ailments of women and children. Is the enormous experience of army medical officers in tropical diseases to be ignored as well as in the injuries incidental to active service? I would also inform him that excellent surgery on the brain, thorax, and abdomen is carried on outside Netley by juniors, who are not restricted by seniors in many civil hospitals. He declares that an ambulance department will only bring wounded men to surgeons unfit to treat them, and compares the medical services of to-day unfavorably with what they were fifty years ago. How any man in his position could venture to make such wilid assertions passes comprehension. Does he forget that fifty years ago the death-rate of the European army in India often mounted to 89.42 per thousand, as against 1.39 at present? Is he aware that among a large number of wounded during the Northwest Frontier campaign, and notwithstanding difficulties which hospital surgeons in this country can hardly realize, the officers who had lived a 'life of stagnation' reported their hospitals free from septic contamination, without a single case of pyemia or tetanus? Let Professor Ogston show better results anywhere. Notwithstanding that he discourses on inferior qualifications, stagnant lives, being fifty years behind the times, inability to undertake surgical procedure of any magnitude, etc., he nevertheless admits that many of the best men in the profession are in the services, who carry out work of the highest order for small reward, etc. Surely such statements are slightly inconsistent! It is impossible here to notice all the misstatements; but his statement that the weakest men who enter the Indian service are of a class superior to the best who enter the Royal Army Medical Corps is ridiculous. I freely admit there is ample room for improvement in the construction, equipment, etc., of our military hospitals; that field hospitals and bearer companies should be better organized and more frequently exercised; also that post-graduate courses for medical officers are most desirable. But such reforms are more likely to be delayed than furthered by exaggerated statements and reckless assertions; and meanwhile good candidates are scared from the military medical service. The Royal Army Medical Corps have the greatest confidence in Lord Lansdowne, and feel he will effect all real and needed reforms as soon as practicable, notwithstanding Professor Ogston's tirade."

The Abuse of the Army Surgeon.—As a specimen of the poor taste with which the army medical officer is assailed in other countries as well as our own, we quote the following from the British Medical Journal for August 19th:

"An Aggrieved Member" of the British Medical Association writes: As a result of Professor Ogston's address comes the inclosed cutting from the Edinburgh Evening Dispatch, purporting to give a speech by Sir Arthur Grant, Bart., of Monymusk, at a corporation luncheon given at Aberdeen to a detachment of the New South Wales Lancers, which for unprovoked offensiveness it would be hard to beat. This person, who figures in the Army List as honorary colonel of volunteer engineers, and is hardly an irresponsible civilian, is reported to have spoken as follows:

"Professor Ogston, one of the most distinguished surgeons of Europe, had said what, to his personal knowledge, officers of the army had been saying for the last thirty years, that medical officers of the army were ignorant and useless, with, of course, certain brilliant exceptions. There was many and many a man, and many and many an officer's wife, who did not dread being shot or injured, but very much dreaded falling into the hands of the army medical department. For himself, he would much rather be shot by half a dozen Boers than be butchered by one army doctor." [Laughter.]

Up to this the Journal remarks: "We do not think Professor Ogston will at all accept this libelous post-prandial nonsense as representing his views of the army medical service."
Original Communications.

ATYPICAL FORMS OF PNEUMONIA.
A CLINICAL STUDY.*
BY E. PALIER, M. D.

Pneumonia has been ably and abundantly described by more competent authors than myself, and therefore very little will be said here with regard to typical forms of this disease. But we occasionally meet with an atypical form of this malady, which is apt to baffle and mislead the skilled and experienced practitioner; and this will form the subject of this paper, based upon the study of a hundred cases of pneumonia which have come under my observation within the last few years. Most of the cases occurred under very antisyphigienic conditions, in the tenement-house districts, without having had the attendance of a trained nurse. This may be of additional interest, so far as results are concerned, corroborating the assertion made by some that in pneumonia the least treatment is the best treatment. The subject will be treated under the following heads:

Cases will be described as briefly as possible to illustrate each variety of the disease, with some general remarks that are relevant to the issue.

1. Gastric Pneumonia.—In this, like in any other febrile affection, there is always some disturbance of the alimentary canal, and there is nothing new about it. But we occasionally meet with a case of pneumonia in which the abdominal disturbances are so great as to lead to the belief that the main seat of the disease is in the abdomen. The following instructive case, which will be described at some length, will illustrate this point:

L., a boy, aged six years, born in New York. Family history: Father had been treated by me several months previously for hay asthma, which he stated was his first attack; otherwise, family history is good.

The boy had had measles several years before, from which he fully recovered, and had been a healthy, bright boy up to about ten days prior to the malady in question, during which ten days he suffered from indigestion, his bowels being costive. On February 15, 1897, in the evening, he had a sharp and severe chill which, according to his parents’ statement, lasted about half an hour. I saw patient the next day, February 16th, and found him as follows: Face flushed; conjunctive red; delirious; temperature, 106° F.; pulse, 140. Bowels constipated. Physical examination negative. Calomel in half-grain doses and phenacetin were prescribed, and patient on the third day was in the following condition: Lying on his back and screaming from pain in the abdomen; bowels had not moved; a flush on the left cheek corresponding to malar bone; temperature about 104°; pulse, 130; and patient’s mind clear. Physical examination: Some dulness on percussion and bronchial breathing on right side of chest, posteriorly, below scapula, for an area about two inches in diameter. An examination of the abdomen revealed slight tympanites in the epigastric region and pain on pressure in the same region, but no tumor could be felt. Saw patient again on the next day, February 18th; constipation not relieved, though calomel had been given freely, enemata of water and castor oil and of glycerin administered, and other antispasmodics and laxatives tried. Patient in the same posture as on previous day, and urgently demands to be relieved of pain, which he refers to the abdomen. Physical examination of chest shows dullness and bronchial respiration in the same area as on the previous day. An examination of the abdomen shows it distented, bulging, and tympanitic; pain on pressure all over the abdomen. In such a condition of the abdomen it would be, of course, impossible to feel any tumor even if it were present, unless patient were brought under an anesthetic. Temperature and pulse nearly the same as on previous day, and the flush on the cheek, by the way, still remaining.

At this stage of the disease Dr. II., a prominent pediatricist, was called in consultation, and he diagnosed the case as peritonitis, due probably to appendicitis, and advised an immediate operation. Patient was transferred the same day to one of the city hospitals and operated on immediately for appendicitis by Dr. E. I was present at the operation. Appendix was found healthy, and was not, therefore, removed; there was no peritonitis. The operator thought he found a twisted loop of the small intestines in the epigastric region, but it slipped back into place as soon as he had put his hand on it, and he could not demonstrate it to those present. He was himself inclined to think that there was no serious lesion in the abdomen. Patient died twelve hours later, and autopsy was performed by a coroner’s physician. I regret to say that I came too late for the autopsy, but the house surgeon then informed me there was an empyema found in addition to a pneumonia, and that nothing was found in the abdomen. As no notes were taken from the post-mortem, so far as I could ascertain, no detailed information of it can be given.

This case presents a double interest—first, the accompanying empyema; secondly, the severe abdominal disturbances simulating disease in the abdomen.

Let us consider now the first part. The pleurisies occurring in connection with pneumonia are divided by Nettet and Lemoine * into parapneumonic and meta-

pneumonic. The former occurs with the pneumonia and is not considered as a complication, but as a part of the pneumonic process. When the pneumonia is located at the periphery of the lung, the pleura is more or less involved, and, as Flint expresses it: † "In a strict sense, nearly every case of pneumonia is pleuro-pneumonia."

But the parapneumonic pleurisy is very seldom purulent; it is, as a rule, serofibrinous. Thus Schlesinger

* Lemoine. Semaine médicale, vol. xii, p. 12, 1897.
† Flint’s Practice of Medicine, p. 66
found only two parapneumonic empyemas in his one hundred and seventy-three cases of pneumonia in children, whereas the serous variety occurred more frequently. The metapneumonic pleurisy appears after the pneumonia had apparently been resolved, and there was some period of defervescence lasting from a few days to a few weeks, and it occurs mostly in debilitated subjects. Metapneumonic pleurisy is, according to most authors, frequently caused by a preceding pneumonia; and when in pneumonia a decline of fever is followed after a short period by a recrudescence, it is said that pleurisy must be suspected, and in doubtful cases Osler recommends the use of the needle to clear up any doubt. Under the head of wandering pneumonia, however, I will bring cases to show that an exacerbation following a defervescence in pneumonia may be due to a secondary attack of pneumonia. Metapneumonic pleurisies are, as a rule, purulent.

Empyemas are divided by Netter,† on a bacteriological basis, into (a) simple purulent, (b) tuberculous, and (c) putrid.

The latter two do not concern us here and will therefore be omitted. The first variety, namely, simple purulent pleurisy, is the one which, according to most writers, complicates pneumonia. According to Holt, ninety per cent. of empyemas in children are metapneumonic.† This seems to be the prevailing view of most authors.*

Thus it will be seen that whereas metapneumonic empyema is considered a frequent complication, especially in children, parapneumonic empyema, on the other hand, is considered to be a rare occurrence; and when it does occur, it is frequently overlooked, and is discovered in many instances only at the post-mortem. A parapneumonic empyema very frequently does not modify the pneumonic signs, and there may be dullness on percussion and bronchial respiration in connection with it, and hence the reason why it is overlooked.

It would seem to me that when in a case of pneumonia the severity of the symptoms is out of proportion to the extent of lung involved, as it was in my case now under consideration, an empyema can be suspected, and the hypodermic needle should be resorted to in order to make the diagnosis certain.

It must be said here that simple as the operation of inserting the needle is, in private practice, among the ignorant it is not always easily accomplished, especially in the case of children, as some mothers object to their children being punctured; and a friend of mine, an able practitioner, once met with a very unpleasant accident.

The father, who was holding the child, suddenly twisted around when the needle was introduced; the needle broke and the distal portion disappeared in the chest and could not be recovered. What the father said and wanted to do to the doctor need not be told.

Let us now consider the other interesting feature of the case—the abdominal disturbances.

In order, however, to facilitate the discussion let us recall to our mind a few physiological data with regard to the vagus nerves. These nerves supply motor, augmentor, fibres to the stomach and intestines; they contain the afferent, sensory, fibres of the stomach at least, the afferent nerve fibres of the intestines not having yet been satisfactorily established; they contain the inhibitory fibres of the heart, and finally the vagi are potent factors in respiration.

Now it is perhaps needless to say that the nervous energy of any nerve centre, and consequently of all the nerve centres, is limited; for we know well that the nerve centres can do at any given moment only a certain amount of work, beyond which they become exhausted and can do no more. Now, in pneumonia the frequency in respiration is more constantly increased than in any other acute disease.†

It would be unprofitable for us to speculate on the reasons of this phenomenon, but we know that it is so. It stands to reason, then, that in increased respiration there is a greater demand and expenditure of nervous energy in the pneumogastric nerve centres, and the excessive amount withdrawn and spent on respiration would otherwise be transmitted along the augmentor fibres to the abdomen and the cardiac inhibitory fibres to the heart. As it is, the nervous energy transmitted to the abdomen is deficient, and owing to the very same deficiency it does not come down in a regular continuous stream, but in puffs and spasms, and this is also the case with the inhibitory fibres of the heart.

Bearing this in view, we can rationally explain the abdominal disturbances and the cardiac failure in connection with pneumonia. The pain in the abdomen can be explained on the same physiological basis as the pain in the knee in hip-joint disease. In many instances the pain is not due to any abdominal lesion, for all the abdominal symptoms are removed with the disappearance of the pneumonia, but the abdomen being a more sensitive and frequent seat of pain than the chest in those exempt from chest diseases, the pain transmitted to the brain is generally referred to the abdomen. The constipation and cramps are due to the deficiency in the abdominal augmentor nerves, as explained above. The frequent cardiac failure in pneumonia in adults can also be rationally explained on this physiologicomechanical principle. There being a deficiency in the

‡ Loomis. Pepper's System of Medicine, vol. iii, Pneumonia.
§ It might be said en passant that this is probably due to the irritation of the nerve endings of the vagi in the pulmonary alveoli.
nervous energy transmitted along the cardiac inhibitory nerves, the regulating inhibitory nerve influences are gone, and the heart thus working for some time gets tired, becomes irregular, and is apt to fail altogether, a similar occurrence taking place when the pneumogastrics are severed. This seems to me to be a more plausible explanation than the toxæmic theory, which claims that the toxines affect the cardiac nerve centres; for, first, it does not explain how this is done; secondly, why is cardiac failure more frequent in pneumonia—where, by the way, the muscular structure of the heart itself is not very often affected,* and paralysis of any muscle or group of muscles a very rare complication—than in other diseases in which general toxæmia is profounder and more marked, as, for instance, malaria, small-pox, etc.; and thirdly, which is the most important objection, why do not the toxines affect the hearts of young children, as it is generally admitted that heart failure is not a frequent occurrence in pneumonia in childhood? The explanation given above will remove this objection, for the distribution of nervous energy from the higher nerve centres to the body is not the same in children as in adults, and the heart in childhood has not yet become greatly accustomed to the regulating inhibitory nerve influences. The frequency of convulsions in childhood will prove this, as well as explain itself. My theory will also explain why, unlike other febrile maladies, there is no uniform ratio between the increased frequency of the respiration and the pulse in pneumonia, because the nervous energy varies in different individuals.† And hence the rational treatment in threatening cardiac failure in pneumonia is with strychnine or nux vomica, which were so highly recommended by the late Alfred L. Loomis, as they cause an increased discharge of nervous energy and laryn, so to say, the cardiac nerve centres to supreme efforts to tide over the crisis. Digitalis, which is so much spoken of in this connection, I think is only indicated when the heart’s action is irregular, and it can serve only as a heart tonic,* but it does not increase the discharge of nervous energy, and when necessary the two should be combined and the main reliance put on strychnine.

Since then I have seen other cases of pneumonia with obstinate constipation and rather alarming abdominal symptoms, both in children and adults; but when one is certain from a careful examination of the abdomen before the tympanites has set in—for then, of course, manipulation of it is not easy—that he could not detect an abdominal lesion, by waiting a little (meanwhile applying hotcompresses to the abdomen to relieve pain, and doing whatever else is possible) the abdominal symptoms will disappear either before or with the subsidence of the pneumonia.

By studying the history of the case as described above, with a little carefulness, the diagnosis of an abdominal lesion would not have been made. There was no vomiting in that case, no tenesmus, or bloody stools, and there had been, before the tympanites made its appearance, no tumor or mass.

The twist of small intestine, which the operator claims was reduced as soon as he put his hand on it, could not have been any pathological lesion, for the only thing it could have been is a volvulus, and even this is not so easily reducible without leaving any marks.†

2. Cerebral Pneumonia.—Not much new can be said on this subject, as cases of pneumonia simulating cerebral diseases have been described by authors; but a case has come under my observation which so closely resembled tuberculous meningitis that it could easily be mistaken for it. This occurred in a male, two years old, whose family history will be given under another heading, who previously had had cholera infantum, then whooping-cough, followed by diphtheria, and soon afterward by pneumonia involving the whole lower lobe of the left side. A few days after the onset of the pneumonia—the accompanying temperature, by the way, not being above 104°—nervous symptoms made their appearance. There was almost constant twitching of the right upper and lower extremity, grinding of the teeth, and the hydrocephalic cry. Taking into consideration the child’s history, the advent of meningitis would not be surprising; but the pupils were found to react to light moderately, and that was, in fact, the only point against meningitis. Patient recovered, but died several weeks later from acute Bright’s disease, complicated by pulmonary oedema. In another case, a boy, four years old, simple meningitis complicated the pneumonia, and the patient never recovered.

The meningitis complicating pneumonia is considered by authors to be non-tuberculous,† and there seems to be no relationship between pneumonia and tuberculous meningitis.

3. Wandering Pneumonia, called by the French pneunomie à réchute.—Here I shall briefly describe cases in which occurred an exacerbation of symptoms after a crisis and some period of debervescence. Two such cases came to my notice, and in both the pneumonic process appeared in the second lung after it had apparently been resolved in the first. One was in a boy nine years old, who was too weak and small for his age, having previously had a whole list of afflications,

---

* Dictionnaire encyclopédique des sciences médicales, t. xxiv, sec. 2, p. 205.
† Ibid.
‡ Another theory ascribes the frequent heart failure in pneumonia to the obstruction in the lesser circle, and assumes that children’s hearts are stronger; but we know that in other pulmonary diseases where the obstruction is as great, cardiac failure is not so sudden or frequent; and in diphtheria children are subject to it.
* I use the word “tonic” for the lack of a better one.

---

which had left him in a debilitated condition, and whose family history was not of the best. At first the right middle lobe of the lung was involved; there was great prostration, semicoma, and a temperature of 105° F., and sometimes a little higher. On the eighth day there was a crisis with defervescence and patient apparently convalescent. About thirty-six hours later, however, there was another chill with a recurrence of symptoms. The patient's prior history made the onset of an empyema very possible, and a thing to be expected. An examination of the chest revealed dullness and bronchial breathing in the left middle lobe. After two days there was another crisis, and patient speedily recovered. The other case was in a younger child with a similar history. The period of defervescence in this case lasted several days, and the second attack, which also occurred in the other lung, lasted for about five days. In both cases the temperature was a degree or two higher than normal during the period of defervescence. The onset of the secondary attack of pneumonia in such cases greatly resembles an attack of metapneumonic empyema, which was referred to above.

It sometimes happens, however, that the pneumonic process involves a second lobe of the same lung before resolution has taken place in the primarily affected lobe. Again, recently a case came under my observation in a girl, seventeen years old, in whom the two right upper lobes had been first involved, and several days later the middle left lobe was attacked. The process in the left lung was resolved on the sixth day, and it was marked by a crisis and a fall of several degrees in temperature. The pneumonia in the right lung, however, persisted several days longer, but finally disappeared, after having lasted for two weeks, and patient recovered completely.

4. Abortive Pneumonia, called by Dr. Kuhne Rudimentary Pneumonia.—Under this title I wish to refer to cases which last only a few days, terminating in recovery, and in which the physical signs do not plainly manifest themselves.

Some authors, in forming tables of pneumonia cases, mention cases which recovered on the third day. I do not know whether they mean cases of rudimentary pneumonia, to which I refer, or cases in which the physical signs were plainly revealed. It must not be forgotten that generally the physical signs in this disease do not fully appear before the third day.

Personally, I have not often met with dullness and bronchial breathing before thirty-six hours elapsed after the invasion, and only once seen a fully developed case of pneumonia terminate on the third day.* It is permissible, I hope, to doubt the accuracy of the believers in the abortive plan of treatment, who claim that such or another remedial agent cured the pneumonia in three days. I might mention here a case of another nature, which occurred in a girl fifteen years old—a sister of the little patient who had a secondary attack of pneumonia, referred to above under another heading—who was sick for nine days and recovered, and in whom there were no signs of lung consolidation, there being right along in the base of the left lung crepitant rales, or rales at the end of inspiration, heard generally at the initial stage of pneumonia. The onset, termination, and symptoms in this case remove any doubt in my mind as to its nature. But what I wish to refer to here in particular is a case of the following kind, which is often very puzzling:

A boy, ten years old, was sent out of an orphan asylum on account of an epidemic of typhoid fever which broke out there. Seven days later the boy became ill rather suddenly, according to the mother's statement, with a chill and fever. I saw him on the second day of his illness, when he had a temperature of 103°; pulse 110, cheeks slightly flushed, headache, and general weakness, but no pain anywhere in particular. Tongue only slightly coated, and very little disturbance of the alimentary canal. No throat inflammation. An examination of the lungs revealed a few transitory bronchial rales; patient had slight cough and increased frequency in respiration. This lasted for three days, at the end of which there was a crisis with profuse sweating, defervescence; and at the end of four days patient was well, except for weakness. At the end of the third day I detected a rude prolonged expiration, but not bronchial, which I had not noticed before, though carefully examined, at the inner border, near the inferior angle of the scapula, on the left side, which disappeared later.*

The fact that the patient came from a locality visited by typhoid fever makes the case more perplexing. But taking into consideration the sudden onset and termination of the disease, and the very slight disturbances of the alimentary canal, I think that typhoid fever can be safely excluded. The diagnosis then hinges between pneumonia and simple continued fever, an affection on which so much stress is laid by some authors.† Were it not for the trustworthiness and eminence of the authorities who describe such a fever, it might be permissible to doubt its existence, for it is difficult, theoretically, to conceive a fever without an underlying cause, and it might be questioned whether many of the so-called simple continued fevers are not really cases of rudimentary pneumonia. On the other hand, since under this form of pneumonia I understand cases in which the physical signs are not fully revealed—for otherwise it is no more rudimentary, as said above—the diagnosis of pneumonia in such cases is very uncertain, and we are not certain that it is not

* In young children the respiration in this region is normally very often rude, almost bronchial, and hence very frequently deceptive. But the rudeness is generally on forced respiration, when the child cries, and very seldom on forced expiration.

† Pepper's System of Medicine, vol. i, pp. 231–236.
something else. As these diseases seldom cause death, we have no post-mortems to settle the diagnosis.

5. Chronic Pneumonia.—By this I do not mean the chronic interstitial fibroid pneumonia described by writers, but I propose to consider here both croupous and catarrhal pneumonia which are subacute from the onset and last for months and sometimes for years, terminating very frequently in recovery. Some of these cases are attended with haemoptysis, sometimes very profuse, and some run their course without any haemorrhage. These cases closely resemble pulmonary tuberculosis, both the acute and the chronic, with which they are frequently confounded by physicians—a point to which I shall revert soon.

A brief description of some cases will elucidate the subject better:

Mrs A. L., mother of the little patient mentioned under cerebral pneumonia, had been in good health prior to her illness in question, and her family history, according to her statement, is good. She became ill suddenly with a chill, pain in the left side, cough, headache, and weakness; she would, however, creep around the house, and even go out for treatment at a dispensary. I first saw her in this affection, when she had been sick already a few weeks, and found her as follows: Pulse, 110; temperature, 102°; greatly emaciated, headache, pain on swallowing, and exhaustion. An examination of the throat revealed congestion and redness of the pharynx, and the lungs were in the following condition: Dullness on percussion and tubular breathing at the base of the left lung posteriorly extending to the side and in front as far as the nipple. Above this consolidated area, in a zone about two inches, were heard fine crackling râles. At the apex were heard a few coarser râles, which, however, were not permanent and frequently shifted their position; the same in the right lung as in the apex of the left. Patient was sick with slight modification of symptoms for four months, after which she completely recovered. During her illness patient had several attacks of haemoptysis, losing each time about four ounces of blood. This was easily controlled by twenty-drop doses of the fluid extract of hydrastis, every three hours. Sputum, which was thick and greenish-yellow, was examined by the board of health; no tubercle bacilli. A similar case occurred in another woman, thirty-nine years old. This patient had been suffering previously from a cough, and, as I had not seen her before her malady in question, I can not say anything with regard to this cough. This woman's malady was also rather sudden in onset. Her pulse and temperature were of the same range as in the other case; but in this woman temperature and pulse would sometimes drop to normal, and she would have frequent rigors lasting for about an hour, especially in the afternoon, when her temperature would rise a few degrees, and her pulse increase; but there was no periodicity in her chills, and malaria can be safely excluded. In this case both lungs were involved, the left posteriorly from the scapula to the base, and on the side and in front as far as the nipple. There were in this area signs of consolidation, and above, a narrow zone of fine crackling râles. In the right lung there was a consolidated area along the vertebral border of the scapula. A few transitory bronchial râles would be heard in the healthy portions of the lung. A hypodermic needle was introduced in the consolidated lung area, and a few drops of serum, slightly tinged with blood, withdrawn. The sputum was examined by the board of health, and no tubercle bacilli were found. The woman recovered after seven months' sickness. I have examined her recently, a few months after her recovery. Her pulse and temperature are normal, and she attends to her housekeeping.

She feels pretty well, but is troubled a little with her old cough, and the recent examination of the lungs showed rather faint inspiration and prolonged harsh expiration, but not tubular, in the left lung posteriorly. The area that was affected in the right lung can not be distinguished from the rest of the lung. She has now some bronchitis and emphysema, which is probably the cause of her old and new cough.

This case was diagnosticated as consumption by an old practitioner with an immense practice. Such cases must be regarded as subacute or chronic cases of croupous pneumonia. The accompanying pleurisy is not more than in any ordinary case of acute pneumonia peripherally situated. The slight bronchitis is what one would expect in such cases, as some authorities claim that even acute lobar pneumonia is accompanied by a greater or less degree of bronchitis, and Aufrechten believes* that pathologically we can not draw a line between catarrhal and croupous pneumonia. And, clinically, we sometimes meet with a case in which the consolidated area of lung is too extensive for a lobular pneumonia, and the various and numerous râles all over the rest of the lungs are too pronounced for a lobar pneumonia.

In another case, subacute lobar pneumonia in the middle and partly in the upper lobes of both lungs, occurred again in a woman thirty-two years old, whose history was good, and lasted nearly three months, terminating in recovery. Four cases of chronic catarrhal pneumonia, some of them attended with fibrinous pleurisy, have come to my notice, one in a boy four years old, another in a young woman, and the other two in old men. The boy had attacks of epistaxis, and the other cases were attended with haemoptysis, and in one case, a man aged fifty years, it was very profuse. In this case both lungs were involved and it was accompanied with fibrinous pleurisy and abundant, very fetid, expectoration; there was considerable increase in temperature and pulse. There were no tubercle bacilli. The patient recovered after four months' illness.†

In the other cases, in two of them the left lung being principally involved, there occurred recurrent attacks of lobar pneumonia. The child's case is interesting. He had been sick for two years when I first saw him. There was an increase in pulse and temperature, and cough, with physical signs of bronchopleuropneumonia in both lungs. While under my observation a lobar pneumonia was ingrafted, involving

† This case was seen in consultation with Dr. A. Jacobi.
PALIER: ATYPICAL FORMS OF PNEUMONIA.

[Palier's note]

an extensive portion of the right lung at the base, and there was a recrudescence in pulse and temperature. The mother, however, did not notice the child's aggravered condition, and when asked the reason, she answered that the child had had fever and cough for the last two years, and also several attacks of pneumonia, from what the doctors had told her, so that she did not consider the child's aggravated condition as anything extraordinary. The patient recovered from the lobar pneumonia on the ninth day and was under my observation for over half a year, occasionally improving somewhat, and relapsing again. The same results with regard to the other two patients, who also had several attacks of lobar pneumonia.

Subacute croupous pneumonia resembles in its physical signs the advanced stage of chronic pulmonary tuberculosis; the symptoms also closely resemble chronic tuberculosis. Sore throat, which is regarded by many as a characteristic of consumption, may occur also in pneumonia, and some cases of consumption run their course to a fatal termination without sore throat. The difference between the two affections is in the mode of the onset, that of subacute pneumonia being rather sudden, and that of chronic tuberculosis being insidious. A microscopic examination of the sputum will settle doubtful cases.

Chronic catarrhal pneumonia resembles in its physical signs and symptoms acute pulmonary tuberculosis, and it resembles the initial stages of a diffuse chronic pulmonary tuberculosis not only in its physical signs, but sometimes also in its symptoms. The only point of difference between the two affections is the emaciation. There is always emaciation in consumption, whereas in chronic catarrhal pneumonia it is not well marked. A microscopic examination of the sputum will make the diagnosis certain.

Before dismissing the subject, I will mention in this connection unresolved acute pneumonia. Those are cases in which the symptoms are very severe at first, and in several days there is a crisis with some dercurrence, but not complete, and resolution is delayed sometimes for weeks, the case terminating according to the condition of the malady and the patient. One case is worth mentioning.

It occurred in a boy five years old, whose mother, Mrs. A. L., was previously sick with chronic pneumonia and was described above, and whose little brother was mentioned under cerebral pneumonia. Both children sickened nearly at the same time. In this boy now in question, the whole right lung was involved, and the symptoms were very severe. On the tenth day there was a crisis with defervescence, but not complete, and some resolution in upper part of lung. A few weeks later there was an accumulation of some fluid in the affected side of chest.

I happened to absent myself from town for a few days, and the case passed into the hands of another physician. He tapped the chest and withdrew a few ounces of seropurulent fluid. I subsequently learned that the patient recovered.

6. Masked Pneumonia.—Ordinarily the physical signs in pneumonia do not appear till some time elapses after the onset of the fever, as mentioned above; but we occasionally meet with a case in which the physical signs do not appear till the crisis, and then even imperfectly. Such a case came to my notice in a boy, eighteen months old. The invasion was sudden and the temperature high. The whole physiognomy of the case was that of pneumonia, so much so that even the women in the house diagnosed it as such; but there were no physical signs to make a correct diagnosis, though the lungs were repeatedly and carefully examined. On the seventh day, however, I could detect in the left lung posteriorly below the scapula slight dulness on percussion, and on auscultation faint respiration, but no bronchial respiration. On the eighth day there was a crisis, and patient was well on the ninth day. If there could be any doubt in my mind with regard to the physical signs, the termination of the case makes the diagnosis of pneumonia certain. A case of pneumonia in which the physical signs appeared on the sixth day, just at the time of the crisis, is reported by Francis Minot; but the physical signs, when they appeared, were distinct, and in my case they were imperfect.

This is a brief description of the main forms of atypical pneumonia which have come to my notice, though we might as well say a few words with regard to the temperature, which often is only slightly above normal in the morning and rises very high in the evening, simulating quotidian malaria, and called by some malarial pneumonia. The pain is sometimes capricious; aside from the abdomen, it is sometimes referred to other parts. One patient referred the pain to her neck, and did not suspect there was any trouble with her lungs. It appears that she had had some trouble with her neck before. Another patient, again, referred the pain to the other side.

The mortality from pneumonia in children is variously estimated by different authorities from one per cent. to 4.8 per cent. According to von Ziemssen, it is 3.3 per cent. In my own cases I have not met with a case of death from pneumonia in a child when not more than one lung has been involved at the same time, and the mortality, including complications, is as that given by von Ziemssen.

It can be safely said that croupous pneumonia involving not more than two lobes of the same lung in children will terminate in complete recovery, unless it is interfered with too much. As most of my cases oc-

* The advisability of tapping the chest for the presence of such a small amount of fluid might be questioned; but as this does not enter within the scope of this paper it can not be discussed here.

curred in children, it would not be proper to say anything here with regard to adults. Double pneumonia is serious, but in children only two cases came to my notice—one, after the patient, a child two years old, had been sick for four weeks and treated by other doctors. This case terminated fatally after five weeks of sickness. The other has occurred recently and the patient is now tediously recovering.* Only in one case, mentioned above under unresolved pneumonia, was there a collection of seropurulent fluid in the chest cavity. Now, taking into consideration the fact that most of the patients lived amid very antihygienic surroundings and many of them were in a debilitated condition, and yet, to the best of my knowledge, only in the case mentioned above am I aware of pleuritic complications, I am inclined to think that metapneumonic pleurisy is not a very frequent complication, and am tempted to believe that if local applications to the chest of heat or cold, cupping, and other meddlesome interference are avoided, metapneumonic pleurisy will not occur frequently.

The duration of the disease in my normal cases has been from six to ten days.† The following plan of treatment has been followed: The first few days, liq. amm. acet., combined with sweet spirits of nitre, is given, the dose and frequency according to age and condition of patient; as a rule, however, the minimum doses are used. No antipyretics of the coal-tar products, unless temperature rises above 104° F., then only a few small doses of phenacetin to reduce it one or two degrees. Small doses of calomel in tablet form, in constitution with coated tongue. About the fifth day or thereabouts, if there is great prostration, small doses of tincture of nux vomica, repeated as may be indicated. In adults, when there is flagging of the heart with irregularity, the nux vomica is combined with the tincture of strophanthus or with digitalis and administered till some effect is produced, when the dose and frequency are diminished.

In delayed resolution, when there are rales and difficult cough, carbonate of ammonium is exhibited with advantage, which may be combined with nux vomica. Washing the body with alcohol and water as often as may be indicated frequently reduces temperature without any antipyretics. No local applications of any kind to the chest were used. Very little alcoholic stimulant was given, except when prostration was great, when small doses of brandy were administered, more to ease the conscience than with a view to doing any good. The diet consisted of boiled milk, barley or oatmeal water, according to the condition of the alimentary canal. There is no originality in this treatment; I simply state the plan of treatment and the results, and I think that in a case of pneumonia of ordinary severity no special therapy is necessary or advisable, as the case will, in all human probability, recover with very little treatment. In the case of the child described under masked pneumonia only small doses of calomel and bismuth were exhibited for the alimentary disturbance, as other drugs seemed to disagree with the patient, and were therefore abandoned, and the patient recovered just the same.* This might perhaps have been the same also with the other cases; but somehow or other it is impossible for us to willingly abstain from doing something for our patients.

The golden rule to be followed in the treatment of croupous pneumonia, especially in childhood, is to interfere with the course of the disease as little as possible, unless interference is absolutely indicated.

191 Henry Street.

HYSTERICAL BLINDNESS.*

By ARTHUR T. MUZZY, M.D.

In studying the subject of hysterical affections of the eye I have met much difference of opinion as to its real frequency. From the fact that hysteria simulates nearly every organic and local disease, it is not strange that some confusion is met with in the study. No doubt, cases may be forced into the class of hysterical eye troubles by a method of exclusion—that is, from ignorance of the true nature of the symptoms presenting. It is, however, evident from the records reviewed that hysteria affecting the eyes is not very frequent.

While most writers in generalizing state that young girls are the most frequent victims, the cases reported do not support such a statement, as few of such reports are under twenty years, and from this age to forty-five or fifty the numbers run quite impartially. Cases are encountered among males, but only in about the same proportion that holds in hysteria with other and more customary manifestations. De Schweinitz, in his work on the eye, in his brief description of hysterical blindness makes the following points: It occurs usually in girls and women, sometimes in males. The loss of sight is complete and is almost always on one side. The pupil reacts promptly when the sound eye is covered. The ophthalmoscopic picture is normal. Many patients have achromatopsia or dyschromatopsia, and hemianopsia besides. Two points he does not mention are suddenness of the onset and the anaesthesia of the conjunctiva and cornea. Very frequently the blindness is complete at once. And as the vision returns, it may come at the centre of the field or as a contracted field, with a scotoma or blind section near the centre. Many

* The disturbances of the alimentary canal, by the way, in this case made it still more perplexing before the appearance of the faint physical signs and the crisis.
† Read before the Society of the Alumni of the City (Charity) Hospital, May 10, 1899.

* This patient recovered completely in about seven weeks.
† Except the cases mentioned under abortive pneumonia and chronic pneumonia.
times, however, instead of complete blindness, sudden dimness comes on at first, and deepens more or less rapidly to complete loss. Those observers who speak of anæsthesia of the conjunctiva or cornea say it is characteristic. Yet it is certainly but seldom mentioned, and some note its absence. Another point is sometimes recorded that should prove of considerable help in diagnosis—that is, that during testing by lenses, ophthalmoscope, and perimter the vision varies, growing worse from the low nervous vitality of the patient, often being accompanied by photophobia and profuse lacrymation. Sachs, in his paper before the Ophthalmic Section of the academy last December, stated that a strong argument for hysteria in any eye case was an unusual association of symptoms with great variation in the symptoms. The prognosis in all forms is good, though the condition may persist for months, and even years.

Of the forms in which hysteria affects the eye, by far the most frequent is concentric contraction of the visual field. The next in frequency is disturbance of the color sense—achromatopsia and dyschromatopsia. Frequent mention is made of a true functional ptosis, and a few record paralyses and paresis of the recti muscles, especially the external or abducens. Buchanan, in the Lancet, describes quite at length paralysis of both abducens, and Pooley, in the Medical Record, refers to paralysis of one. Baruch and Peek, in the Medical Record, also describe the case of a young man of twenty-one years who, with other symptoms of ocular hysteria, had diplopia. Hemianopsia is recorded by a few, though a true functional hemianopsia is doubted by many of the best observers. Noyes, however, refers to such a condition reported by Pflüger, and Dana also mentions its occurrence. Lagrange describes with much care hysterical uniocular diplopia. This strange phenomenon is of two kinds. The majority are of optic origin, with irregular refraction, due generally to spasm of accommodation, and this causes two or more images on the retina. This optic or peripheral form is mostly a polyopia. The second variety and still more rare is central and due to irritation of the visual centres, described by Duchesne, of Boulogne, in 1864. Lagrange illustrates with the case of a girl of twelve years who, after headache, photophobia of the left eye, and sleeplessness for a short while, was subject to a sudden permanent diplopia of the right eye, which was emmetropic; the vision was only \( \frac{1}{2} \). There was characteristic hysterical dyschromatopsia with complete anesthesia of the conjunctiva. The false image was above and from four to five centimetres distant from the true image, without regard to how far away the object was.

It should be borne in mind also that hysterical manifestations may come on in one suffering from specific disease or cerebral tumor or other organic disturbance of the brain. The diagnosis here often becomes difficult and only to be positively made after careful and more or less lengthy watching and study of the individual case. Hubbell, of Buffalo, in the Buffalo Medical Journal, with two other cases, describes as hysterical the following: A young woman of eighteen had sudden complete loss of sight in the left eye, which faded gradually by scotoma to normal vision. This came on immediately after hemicrania. Two years before she suffered from malarial fever and had no previous hysterical history. The left pupil was sluggish when exposed alone.

To still further exhibit the difficulty of diagnosis, I may say that I have under my own observation at present a woman of fifty-five years, showing concentric contraction of the left field with (at her last examination, February 18th) a large central scotoma. The patient's history, given by Dr. Rupp, shows that she is nervous, hard worked, and perhaps unnecessarily anxious, with no clear hysterical paroxysms; but has frequent severe headaches. Five years ago she fell, striking the back of the head, and for a year there was confusion vision with diplopia, which gradually passed off. In August of 1898 she suddenly noticed a difference in the vision of the two eyes. Examination on September 22, 1898, by the ophthalmoscope showed fundus fairly normal except a possible smallness and tortuosity of vessels in right eye, especially arteries. Vision, R. E., \( \frac{1}{2} \), w. + 72", 45° = \( \frac{1}{2} \), and L. E. \( \frac{1}{2} \), w. + 36° = \( \frac{1}{2} \). Jag. 12", with + 20° = No. 1 slowly. On February 18, 1899, she was again seen. Vision had diminished to R. E. 45", accepting no glass, and left eye saw the large white test card at 4', but not letters. By perimeter a central scotoma was made out, a white fog with rather sharp limits. The ophthalmoscopic picture was the same as last fall. The pupils were normal and similar in size and action. The examination tired the patient, bringing on photophobia and lacrymation.

Treatment in these cases is very unsatisfactory. Arthur Booth, in the Medical Record, promises a good deal with hypnosis or the suggestive treatment. But Millbury, also in the Medical Record, fails almost wholly with it. As to other forms of treatment, very little can be said; the general condition of the patient, rest from overwork, nerve tonics, and carefully adjusted exercise, with avoidance of all false and unnecessary excitement, serve best.

100 East Fifty-seventh Street.

**SEASICKNESS.**

By J. CARLISLE DvRvIES, M.D.,
HONORARY MEMBER OF THE INDIAN MEDICAL ASSOCIATION OF CALCUTTA, INDIA.

**SEASICKNESS, or mal de mer, is an important subject to consider, as the suffering caused by it is beyond estimate. In a concise manner it may be described as a peculiar functional disturbance of the nervous system, produced by shock resulting from the motion of the ship. It is not a disease of the stomach or alimentary canal, as is erroneously supposed by some, but clearly**
a functional disease of the central nervous system. By
deduction it would seem inevitable that any mechani-
cal agitation of the body, such as is caused by the roll-
ing, pitching, and tremor of a vessel, would primarily
and chiefly affect the central nervous system, which is
most sensitive to external irritation.

The most prominent symptoms are a state of gen-
eral depression, giddiness, nausea, vomiting, and de-
arrangement of the bowels and urinary secretion. It may
be divided into four stages: Depression, exhaustion, re-
action, and convalescence. The profession has never
been able to solve the problem, and the laity must re-
gard it as beyond human control. The travel across the
Atlantic would be considerably multiplied were it not
for the terrors of seasickness.

Quite a few are under the impression that seasick-
ness is beneficial; whereas, on the contrary, it is de-
cidedly injurious. After an attack one certainly feels
relieved for a time, but very exhausted all the time, and
if it were not for the tonic and bracing effects of sea air,
one would continue sick even after again regaining terra
firma. Scientifically there is no more reason for seek-
ing an attack of seasickness than of diphtheria.

My experience with this interesting disease was
while surgeon on various transatlantic mail and pas-
senger steamers sailing from New York to Amsterdam,
Antwerp, and Southampton. These trips necessitated
frequent passages across, up and down the English
Channel and North Sea. These two immense bodies of
water are rarely calm; generally very rough and choppy.

Vomiting is a symptom of concussion of the brain.
Seasickness is a series of mild concussions. Children
and the very aged rarely suffer from it. Active cere-
bral life is more prone (between the ages of twenty
and sixty), although I have frequently seen children
vomit on shipboard purely out of sympathy, without
previous or subsequent illness. It is most frequently
seen in those of a highly sensitive and nervous tempera-
ment.

One of the very first symptoms of mal de mer in
certain cases is an abnormal appetite, which is developed
as soon as rough water is encountered. The victim is
anxiously awaiting the call to luncheon or dinner. He
is the first at table and gorges himself, but ere long
finds it expedient to immediately and rather suddenly
leave the table, a miserable mortal.

Headache is not an essential symptom of this mal-
ady. Cerebral congestion and vertigo may be present.
Hopelessness is a constant accompaniment of the dis-
case. Pain in the back sometimes is present and pre-
cedes nausea and vomiting.

Constipation is a source of much discomfort, and
should be relieved. Diarrhea may, on the other hand,
be present. Both result from the same conditions. Life
on shipboard illustrates this interestingly. Neuralgic
pains, chilliness, flashes of heat, exhaustion, and sup-
pression of the menses are occasionally met with.

The nausea is quickly followed by vomiting, and is
often sudden and projectile, as from a central cause.
As the vomiting continues, the ejected matter is com-
posed of intensely acid gastro-biliary secretions. All
secretions except the saliva are decreased. The appe-
tite is entirely lost, and there is a marked repugnance
to food, especially to all forms of fat. The mental de-
pression is now very characteristic. Shipwreck and
drowning have no horrors; the victim rather praying
for that speedy death to end his miserable sufferings.
This condition continues from two to five days, vary-
ing in intensity, and followed by reaction. Seasickness
can rarely be mistaken for any other condition, although
it may simulate gastro-enteritis at first. In seasick-
ness the intense nausea and constipation, the constant
and violent vomiting and later retching, and the loath-
ing of food are more pronounced.

In some cases of slight disturbance, a prolonged,
even inspiration as the vessel rises, followed by expira-
dition during descent, thus controlling the movements
of the diaphragm, is efficacious. It has been stated by
Beard, Barker, and others that by the administration
of thirty-, sixty-, and ninety-grain doses of bromide of
sodium three times daily for a week prior to embarking,
and continuing at sea until the danger is past, mal de
mer would be prevented.

The question arises, When is the danger past? When
the sea becomes smooth? When the physiological
effects of the bromide are visible? When the patient
is stuporous from excessive and repeated doses? And
echo answers, “When?” The treatment mentioned
undoubtedly bromizes the central nervous system; but
does it render it less susceptible to the molecular dis-
turbance of the nervous system caused by the motion
of the ship?

In all my fifty-eight voyages across the Atlantic I
have never come across a passenger whom this dosage
affected, except visibly, by giving him a bromism, and
nausea and vomiting just as soon as the steamer en-
tered an area of rough water; also extreme loss of ap-
petite. This is caused by the intensely irritant action of
the sodium bromide on the sensitive stomachs of hyper-
esthetic and nervous patients.

The bowels must be opened before embarking by
either calomel, phosphate of sodium, or a saline purge.
An active purge (saline), either Epsom or Rochelle
salts, half to an ounce, should be taken the night pre-
vious to embarkation, followed by twenty grains of bro-
mide of sodium at 7 A.M. the day of sailing, and this
dose repeated one hour before the vessel sails. Remain
on deck constantly during the passage across, save for
meals and bed. I have had marked beneficial results
with this course of treatment in all cases. Vichy and
Apollinaris should be indulged in freely throughout the
voyage. In those who are seized with mal de mer at sea,
not having previously undergone this preparatory treat-
mant, aromatic drinks, lemonade and champagne, with
imported ginger alc ad libitum, are of great value. Where the bromides can not be retained, these will be kept down.

The position of the patient deserves equally to be taken into consideration; the horizontal proving much more agreeable than the erect posture, as it better supports the stomach and other viscera, and prevents thereby, to a certain degree, their disturbance by the oscillation of the vessel.

A general diet, substantial and succulent food, easy of digestion, with Vichy, or, if stimulation is indicated, brandy or wine, is most beneficial and useful. Such a regimen is nourishing and strengthening, does not oppress the stomach, but acts somewhat as a soothing or sedative remedy. Avoid cold food.

Chapman recommends the spinal ice-bag. While this is good and relieves the spinal congestion, its disadvantage is apparent by the fact that the patient is compelled to remain in the close state room below; and this confinement should by all means be avoided, as whatever good the ice-bag may do, it will be handicapped by the odors from the galleys, and the smell of stale sea water, which may have previously got in during a violent storm, causing the patient to gag and retch, until removed from these surroundings. The motion of the ship is also least noticeable to the patient on deck, owing to the horizontal position assumed, and the invigorating and tonic effects of the air.

Nitrite of amyl in obstinate cases at sea has been tried with success. It should be given in full doses upon the first appearance of epigastric distress, and repeated as necessary. Cocaine has been recommended, but I have never found it beneficial.

In very severe and obstinate cases, after everything has been tried without success or relief, the patient's greatly enfeebled condition and the constant retching demand morphins, but great care must be exercised in its exhibition. The patient should be kept under its influence at least twenty-four hours.

---

**EPHYSEAL SEPARATION OF THE ENDS OF THE HUMERUS.**

**By Michael Lucid, M.D., Syracuse, N.Y.**

The subject which by your courtesy I am at liberty to introduce for discussion to-day is one which is so full of interest, and so important alike to physician and surgeon, that it has been selected by me not alone because of the paucity of research upon the conditions of which I desire to make mention, but because my attention has been attracted recently by some very unique and interesting cases, and, too, because the ever-widening scope of usefulness of surgical methods and appliances occupies the foremost place in the work, the thoughts, and the discussions of practical surgeons.

Having accepted your invitation, I shall discuss only the practical anatomical phases, etiology, diagnosis, and treatment equitably, with a view of formulating such conclusions as may seem justified, and with the hope that I may be able to present an outline of this subject which will prove of interest, invite your criticism, and thus enable me to share your experiences and express the desire to stimulate in the profession a more careful and scientific study of the available methods of diagnosis and treatment.

It is indeed strange that so little has been written upon the subject of epiphyseal separation of the ends of the humerus, either by remote or modern surgeons; but the epiphyseal structures are small, and we are ever conscious of the fact that nowadays most surgeons are looking for larger game.

The subject of epiphyseal separations is still in need of further study, and the knowledge necessary to insure positive results can only be gained by the careful study of many cases upon the post-mortem table.

Nothing systematic, save the brief references extended by Hamilton, Smith, and Moore, has, to the writer's knowledge, been published regarding epiphyseal separation of the ends of the humerus.

Appreciate, if you will, the positive fact that no surgeon has, after improper reduction and faulty fixation of the injury referred to, had perfect movement, and you have sufficient data to justify you in concluding that in no field of general practice is harmonious action of the physician and surgeon more necessary for the results demanded and justly due the suffering patient.

Many are the problems that present themselves for solution in the management of cases of epiphyseal separation of the ends of the humerus, for the proper determination of which all of the practitioner's resources are requisite. Few cases in bone surgery make greater demands upon his tact, knowledge, experience, and judgment, or in which the necessity for intelligent and effective treatment is more urgent.

While I am to report but three cases, I find upon consulting the literature upon the subject that it is sufficiently rare to demand your attention, and from such cases I feel that we can draw valuable deductions when associated with allied experiences which, no doubt, many of you have had.

A brief description of the plan of development of the humerus will enable us better to understand the separation of the epiphyses, both at the upper and lower ends of the bone.

The humerus is developed or originally formed from seven cartilaginous centres—namely, one for the shaft, one for the head, one for the tuberosity, one for each epicondyle, and two for the lower articulating ends of the bone.

The shaft is ossified in nearly its whole length at the
time of birth. Ossification begins in the centres for the upper end of the bone between the first and fourth years, and they coalesce by the end of the fifth year so as to form a single epiphysis, which finally unites with the shaft about the twentieth year of life.

At the lower end of the bone, ossification begins in the radial portion of the articular surface at the end of the second year, and the trochlear portion at the eleventh year; in the internal epicondyle at the fifth year, and in the external epicondyle at the fourteenth year. At the sixteenth or seventeenth year of life all the centres are joined to each other and to the shaft, except the inner epicondyle, which does not unite, by bone, with the shaft till the eighteenth year. It will be observed, therefore, that although the ossification begins in the upper epiphysis first, it is the last to form bony union with the shaft, which process is completed about the twenty-first year of life. It is hence apparent that the superior epiphysis of the humerus comprises not only the head of the bone, but likewise both tuberosities, with that portion of the bicipital groove which is not situated between the processes. Internally, it corresponds exactly to the cartilaginous surfaces of the head of the humerus, but in front, externally, and behind, its line of junction with the shaft passes below the tuberosities.

The supraspinatus and infraspinatus muscles are not, therefore, attached to the lower fragment, nor is there any difficulty in comprehending osseous union, for the head of the bone forms one body with the tuberosities and is richly supplied with blood.

Aetiology.—Epiphyseal separation of the ends of the humerus belongs almost exclusively to the periods of youth and childhood, and is occasioned either by a direct blow or fall upon the shoulder, or by violent wrenching of the arm, as during delivery, causing separation of the superior epiphysis; while separation of the lower epiphysis is the result of a fall upon the elbow, excessive adduction or abduction of the forearm with superextension, or a sudden or unexpected push of the arm which it is unprepared to resist.

Pathology.—Upon dissection in these cases in the young, the head of the os humeri is found broken off at the tubercles, but it remains in the glenoid cavity and does not move with the shaft. The upper end of the lower fragment projects in front, when displacement exists, and is less sharp and angular than in cases of a broken bone. Taking the head of the humerus of a subject ten years of age, parted by maceration, we find the angle made by the junction of the plane projected through the anatomical neck (which makes about two fifths of the whole surface) with the plane passing below the tuberosities measures about one hundred degrees.

The muscles are apt to acquire their greatest tension at the moment of separation, and those whose actions are in direction with the shaft press upward, the head being set upon the shaft at an angle, and, were it not for the muscles attached to the tuberosities, those which act in direction of the shaft would have a tendency to roll the now movable head upon the glenoid surface; but, instead, the muscles attached to the tubercles contract and roll the head in the socket and produce dislocation backward of the facets, which position throws now the superior edge of the diaphysis forward and retains it there. When extension is made, the head works on the projecting angle of the diaphysis, and the tense deltoid muscle, pressing the shaft backward, will restore the rotundity of the shoulder; but the cessation of the extension finds the capsular muscles ready to roll the head out and project the diaphysis forward, and the symptoms return as soon as the extension ceases.

Of the lower epiphysis very little has as yet been written concerning the pathology. The humerus is separated from its cartilaginous expansion at the condyles near the elbow joint, in which case the lower fragment would comprise the entire epiphysis, which is composed of four distinct pieces, but either or both epicondyles may remain attached to the fragment.

Diagnosis.—Notwithstanding the very positive statements with reference to the diagnosis of epiphyseal separation of the ends of the humerus by Sir Astley Cooper, Professor W. W. Smith, and Professor Frank H. Hamilton, one would scarcely suppose that great confusion had existed, and still exists, as regards the exact nature of fracture of the humerus at the point under discussion; but error of diagnosis does occur, and that constantly. I think this results from the fact that a clear conception of the change of position has not been put forth, and more than this, and growing out of it, no method that secures reduction, save that of Dr. Moore’s, which is a most effectual one, yet difficult for some to comprehend, has thus far been proposed. The constancy of the symptoms make this condition differ from most that occur in adjoining structures. The chief diagnostic signs of separation of the upper epiphysis from the humerus are: First, an abrupt projection can be seen and felt on the front of the shoulder about one inch beneath the coracoid process, caused by the upper ends of the lower fragment. Second, crepitus, when felt, is of a softer character than in fracture. Third, the end of the shaft is rounded and smooth, not sharp as in fracture, and has the form of a low cone. Fourth, the immediate recurrence of the deformity when the means employed for its reduction cease to be in operation. The most important practical point with reference to the diagnosis is that the accident is apt to be followed by arrest of development if not properly reduced. These diagnostic and unfailling manifestations deserve to be memorized because they exemplify the great difficulty often experienced in diagnostiating exactly the true seat of the solution of continuity and the necessity that these signs should be
correctly interpreted. The X rays afford, perhaps, the most positive means for diagnosis.

The simple anatomical fact which affords valuable information with reference to the diagnosis of separation of the upper epiphysis is that the tuberosities of the humerus form a part of the upper fragment.

Trealtment.—In view of such a displacement at the upper end of the humerus, the natural mode of reduction would seem to be one that would carry the shaft backward and thus restore the corresponding facets to their normal positions.

The great error that is constantly made is the severe and protracted extension made to reduce the relaxation, which traction may, in a measure, cause the disappearance of the deformity; but the moment the parts are abandoned to the uncontrollable action of the muscles the deformity recurs. The most effectual mode of reduction is by carrying, with moderate extension, the humerus forward and upward. The head will roll upon the glenoid surface in any motion of the arm until restrained by its capsule. Now, then, while the humerus is still back of the central line of the body, the head is rolled upward, and long before the humerus is brought up perpendicularly, the capsule at the lower border of the head has become tense, thus holding it firm; while the humerus, being thrown up and restrained by its muscles, slides the diaphysis backward, producing a coaptation of the corresponding facets. In other words, the reduction is effected by carrying the arm forward and upward, using moderate extension to the perpendicular line with the body.

The retention is effected by moderate extension while bringing the arm down to the side, and maintaining this slight extension until dressings are applied. Moore’s method, which consists of a wooden splint fastened to the outer side of the arm, resting its lower end in a strip of adhesive plaster, while the upper end projects two inches above the shoulder, with a notch through which a bandage is passed under the axilla for extension, fulfills easily and promptly the indications.

With reference to the diagnosis of separation of the epiphysis at the lower end of the humerus, it is easy—on paper. But when the surgeon is called, enough time has usually elapsed to permit of swelling, and with an elbow joint often as big as the calf of the leg, or bigger, and the bony landmarks covered deeply by congested and edematous flesh, I know of nothing more difficult, in reality, than to determine just the nature of the injury.

There may be fracture alone of the humerus, ulna, radius, or any two of these bones, or each may have therewith associated a dislocation, or a dislocation alone may be present. The dislocation is easiest of diagnosis because of abnormal rigidity, but fractures, either singly or with a dislocation, are less easily determined with exactitude. If the beginner in surgery will wrap the elbow of a skeleton in a pillow and try to examine the joint through its depths, he will approximate the difficulty of the case. Could we be sure of dislocation only, our duty is plain: simply to reduce it at once, for any delay increases the difficulty and also invites a stiff joint. Again, if we felt certain of fracture alone, we should feel mentally at ease, for there need be no haste in setting a fracture if the fragments are not badly displaced, because no callus is formed for nearly a week, which time would be sufficient to allow swelling to subside, and reduction could then be exactly performed. But, unfortunately, the surgeon must often be in doubt, because of great swelling, as to the exact diagnosis, and a positive diagnosis obtained at the earliest possible moment has everything to do with good surgery. In this condition also the X rays afford valuable and most reliable aid in early diagnosis. Under such circumstances, the practical point I am about to mention becomes of the utmost value. Put your patient under anesthesia (as is the proper manœuvre in all cases of fracture, unless there is some organic lesion). Now apply an Esmarch elastic bandage, starting at the band and going very slowly but firmly up the forearm, over the swollen elbow joint, and continue until the armpit is reached. Leave the bandage on say for ten or twelve minutes. At the end of that time remove it, beginning at the band, but leaving the final few turns upon the upper end still tightly in situ. The elbow thus exposed will be pale, bloodless, and no longer swollen. All the congestion and edema are, for the time being, caused to vanish.

The diagnosis can now be made with positive ease. The lower end of the upper fragment will be tilted forward, will be prominent, and the elbow joint pushed seemingly backward with limited flexion and extension of the forearm. The lower end of the upper fragment has greater width than any fracture at the base of the condyle and the line of separation is nearer the end of the bone.

Reduction.—An easy mode of reduction is to grasp the forearm and make extension with the knee in the bend of the elbow, adjusting the fragments with the free hand. Now the remaining turns of the Esmarch bandage are removed, and, of course, the swelling promptly returns; but the surgeon has accomplished his purpose. He knows the real diagnosis, applies both an anterior and posterior angular splint, with pressure anteriorly over the seat of separation, is ready to protect his own reputation, and can forecast the outcome with some degree of accuracy.

We all know that it is early errors in exact diagnosis, with resulting unfortunate lines of treatment, which most often subject the practitioner to malpractice suits. The question of passive motion in this separation is absolutely essential to get perfect extension and flexion. This should be resorted to by the surgeon—no one else—about the seventh or eighth day; then about the twelfth
day, and after that every other day until the twentieth day. The fragments should be held in apposition and motion given very cautiously. If after the twenty-second day complete flexion and extension can not be produced, an anesthetic should be given and the adhesions broken up so as to allow both flexion and extension. Many times it is advisable, after provisional callus formation when the fragments are in apposition, to bandage the arm one day extended and the next day flexed. In this manner brilliant and satisfactory results may be obtained.

In the report of the cases which have come under my observation, I desire simply to make reference to three as follows:

Case I.—Boy, aged thirteen, fell from an elevation of sixteen feet, striking on the left shoulder. He was seen soon after by an experienced physician who committed the common error of diagonisticating the condition as a dislocation which, he told the patient, he had reduced. Ten days later, the shoulder was still swollen and painful, and the patient saw a second physician who diagnosed fracture of the greater tuberosity, and referred him to me, without attempting reduction.

The following conditions presented when I saw the boy, twelve days after the accident: The shoulder was flattened from above downward, and appeared broader on profile; three fourths of an inch below the acromion there was a marked prominence having a regular, smooth edge and passing inward to a surface slightly wedge-shaped. The shaft of the humerus was so inclined as to carry the elbow backward and outward. The head of the humerus was in the glenoid cavity, and, when firmly held by rotating the arm, a muffled crepitus was felt.

The patient was placed under ether, and reduction was performed by carrying the arm forward and upward to the perpendicular line of the body, and retention effected by moderate extension while bringing the arm down to the side. The dressing used was the apparatus described above, and was removed in four weeks with perfect motion of the shoulder joint and disappearance of all deformity.

Case II.—Boy of six years stumbled and fell, the entire weight of the body resting on the left elbow, which struck a large stone. I saw the case twelve hours after the accident. The arm was swollen from the wrist to the axilla. At the elbow joint, in front, a marked bulging of the muscular structures was held out by the projecting end of the shaft, which was tilted forward and had a margin that extended the whole width of the humerus, while the joint proper was pushed backward with limited flexion and extension. The diagnosis of epiphyseal separation of the lower end of the humerus was entertained, but, to verify the diagnosis, Esmarch's elastic bandage was applied in the manner described in the foregoing.

Reduction was easily made and the fragments retained by an anterior and posterior right-angular splint, the former having a pad over the seat of separation.

This dressing was left on for seven days. Passive motion was given (not by any member of the family, but by the attending surgeon) by firmly holding the fragments in apposition, which motion was repeated seven days later. Then passive motion was resorted to every other day for twenty days, after which time the little patient had absolutely perfect flexion and extension, as the accompanying photograph will verify.

Case III.—G. R., aged ten years, had suffered a fracture of the right arm two years previous, and a fractured clavicle on the same side eight months before. While skating, he caught his toe and pitched headlong, striking on the left elbow. The arm immediately began to swell, and when I saw the member the swelling extended from the wrist to the axilla. Under an anesthetic, the elastic bandage was applied, and the diagnosis of epiphyseal separation of the lower end of the humerus was made.

Assisted by Dr. Lucian H. Shepherd, the reduction was made by extension of the forearm with the knee in the bend of the elbow. After reduction the elastic bandage was removed and an anterior and posterior right-angular splint was applied. The dressing was left on seven days, when passive motion was given. On the fourteenth day passive motion was given, and after that every other day for twenty-two days, when, not being satisfied that marked progress was being made, the patient was given an anesthetic. The adhesions were broken up and the arm bandaged in an extended position.

In three days the arm was dressed and bandaged in a flexed position for three days, after which time passive motion and massage were resorted to with perfect extension and flexion.

Permit me to add that two other cases of epiphyseal separation—one of the upper and one of the lower end of the humerus—have occurred in my practice, both showing the characteristic separation above referred to, in which reduction was practised by Professor David M. Totman, of Syraeuse, New York. In both cases the recoveries were perfect.

401 Montgomery Street.

CLINICAL REPORT OF
AN EPIDEMIC OF INFANTILE DIARRHEA.

BY ISAAC J. JONES, M.D.,
SECRETARY TO THE STATE HEALTH OFFICER OF TEXAS;
LATE SHERIFF TO THE TEXAS CONFEDERATE SOLDIERS' HOME, AUSTIN, TEXAS.

The present season, beginning as early as the first of April, has been marked in our city by the prevalence of an epidemic of diarrhoea, and not only infants but adults as well have been extensively affected. The disease has also been of a severe and fatal type, as the many little graves in our various cemeteries eloquently testify. These graves also bear witness to the inefficiency of the present treatment of the disease, a question that I will venture to assert is in unsatisfactory a state to the conscientious physician as any in the whole field of therapeutics. The local cause for this sad history is not far to seek, and is embraced in one word—filth. Our city, being situated on a series of rocky and gravelly hills sloping toward the Colorado River, and to the small streams that enter it, is naturally clean, and usually requires but little attention from the sanitary department, and, as might be expected, we have no sanitary
JONES: AN EPIDEMIC OF INFANTILE DIARRHŒA.

[N. Y. MED. JOUR.

department worthy of the name. Therefore, Nature has to do whatever sanitation is done. This is usually very satisfactorily accomplished by the heavy rains which recur with regularity during the winter and spring months, and which wash all filth into the river. By this process the city is usually fairly clean by the beginning of the heated term, and if we are so fortunate as to have a few heavy rains at proper intervals during the summer, we do not suffer to any marked extent from diseases due to filth. This year, however, we had no rain of consequence from the 1st of December until the last of May, thus exactly reversing our usual condition of rainfall. The surface of the ground has been reduced to dust which has penetrated everywhere—as our housekeepers and merchants will testify. This dust has been present in perfect clouds; no substance could be exposed to the air in the slightest manner without receiving a coat of it. A cistern left open but a few minutes, the sideboard, the kitchen safe even, if not airtight, would be permeated. Of course, many articles of daily consumption were thoroughly infected by this agent, many of which reached the stomachs of our population, carrying many infectious germs from the filthy streets and alleys, without the least sterilization. Added to this active source of infection we had during the early spring an unusually high temperature for the season. These factors to my mind satisfactorily account for the epidemic that we have had.

The therapeutics of these intestinal troubles, as might be supposed from the reference to new-made graves above, has not been successful here. We have a capable local profession and they have exhausted the resources of the text-books, but with disappointing results in many cases.

The authors of our text-books are responsible for introducing much confusion into this subject by attempting to make arbitrary anatomical divisions of the disease, which, as has been clearly proved, is impracticable, and which is not at all necessary to a correct knowledge of the pathology and clinical history. For clinical purposes it is only necessary to distinguish between two forms, the dyspeptic and the bacterial, and the latter is frequently the result of bacterial infection in a case of simple dyspeptic diarrhoea. If indigestible food is introduced into a healthy alimentary canal, or if the food is proper and digestible and the canal is not healthy, indigestion occurs and the passage of the food through the intestines is delayed. Though the food may have been absolutely sterile when introduced, fermentation will occur from the presence of that bacterium which is found in all stomachs. This will be followed by a condition of alternate constipation and diarrhoea, which is the dyspeptic diarrhoea referred to above. This condition, if no accident occurs, is simple and easily relieved, as a rule. If the diet is corrected the patient usually gets well at once. If, however, by careless feeding the intestinal tract is infected by any of the many forms of bacteria capable of producing infantile diarrhoea (see Booker, Johns Hopkins Hospital Reports, vol. vii), serious consequences immediately ensue. By reason of the accumulations of fermenting food in the canal, a favorable site for the growth and development of the germs is provided, while at the same time the vital powers are below par. Hence, in treating the simplest form of infantile diarrhoea the greatest care should be observed in the feeding to see that all possible sources of bacterial infection are excluded. I am satisfied that the greater part of our trouble during this epidemic has arisen from a failure to observe and properly carry out this condition. To do so, especially when confronted with an omnipresent and aggressive infection, like the dust described above, and when for the carrying out of your orders you must depend upon unskilled hands whom no amount of instruction will cause to appreciate their prime importance, is a problem of great difficulty. We should therefore not be surprised to find that a large percentage of our simple dyspeptic diarrhoeas result in grave forms of bacterial infection. An illustration of this danger is found in Case I as described below. I had ordered the child to have a meat broth with barley, to be freshly prepared every six hours, and to be kept in the mean time in a sealed container. Observing on my third visit that the patient had grown suddenly worse, and suspecting that my directions were not being properly carried out, I ordered the child to be fed in my presence. I was not surprised to see the mother take from a table, which stood by an open window but a few feet from a very dusty street, an uncovered glass, and proceed to pour from the vessel containing the prepared food. On examining the glass I found it to contain a tablespoonful of the broth left over from the last feeding, which was coated with the dust from the street. This was a woman of at least average intelligence and devoted to her sick baby, and had been carefully instructed. I resolved that in the further treatment of this and other cases of infantile disease it was necessary to select a food that in its nature and method of preparation was as nearly incapable of infection as possible, thinking that this quality was perhaps of more importance in treating this disease than its nutrient qualities.

To obtain the greatest certainty that the food is sterile until it reaches the stomach of the patient, even when administered by the incompetent, the nourishment should always be prepared from hot water, as this is almost universally first boiled and then allowed to cool down to the required temperature. It should also be easily prepared as wanted, and never prepared in quantities. The objection to most artificial foods that meet these two conditions is that, as a rule, they contain no nitrogenous elements, and hence are incapable of sustaining life for any length of time. Those foods that require milk in their preparation are not to be thought of under such conditions as we have had, as the milk
was certain to be infected, and is difficult to sterilize, besides the general objection to milk in infantile diarrhoea that it furnishes a nidus for the bacteria to develop in. Aside from these qualities, the food selected must be in a form to insure its rapid absorption and assimilation, must not tax the digestive organs, and must be entirely devoid of any irritating effects upon the gastro-intestinal tract. More recent investigations, both in physiological laboratories and in clinical practice, would seem to show that proteins administered in the form of albumoses require practically no digestion, are promptly absorbed and assimilated, and entirely free from irritating effects. They therefore represent the most available means of administering in small bulk the greatest amount of albuminous nourishment in the class of cases referred to. While albuminous foods and peptones frequently give rise to digestive disturbances and are apt to excite repugnance, the albumoses are not only devoid of these disadvantages, but have a stimulating effect upon the appetite and digestion.

Bearing these observations in mind, I call your attention to the following cases, each one selected to illustrate some particular point in the treatment of these conditions:

Case I.—C. II., a girl, aged eighteen months, located in a very dirty section of the city, though its immediate surroundings were cleanly and fairly good. Child had been robust and well nourished and had no previous illness. First visit, April 11th. Was attacked on the previous day with severe and frequent diarrhoea with lumpy, acid stools and accompanied by some nausea and a temperature of 100.5° F. I prescribed four powders, each containing English calomel, a quarter of a grain, Dover’s powder, half a grain, and ipecac, a tenth of a grain, to be given every hour until the stools acted freely. I also ascertained that the child had been fed on a miscellaneous diet and milk obtained from the milkman. I ordered this to be discontinued, and the child to be given nothing for the first twenty-four hours but sterile water in liberal quantities, and then to have freshly prepared beef broth sparingly. On the evening of the following day I found the child much better; no fever; discharges from bowels only two, and of healthy appearance and consistency. I ordered diet of beef broth with a little barley, to be prepared fresh every six hours, and kept in the interval in a self-sealing fruit jar sterilized each time used. On the second day thereafter I was recalled and found the patient much worse every way, thin watery discharges from bowels every few minutes, and a temperature of 103.5° F. I was positive that a fresh infection had occurred, and equally so that my instructions had not been properly carried out. The calomel powders as above were ordered repeated, bowels irrigated through a soft-rubber catheter, and the child placed in a tepid bath for ten minutes, which was to be repeated every four hours as long as temperature remained high, and all food except sterile water was discontinued. Next day the child was much better, and diet was ordered with very rigid instructions as to its preparation. Patient improved for two days longer, when I was recalled to find that another relapse had occurred, with the same symptoms as formerly, except that the stools were now of a thicker consistence, loaded with mucus, and streaked with blood. The child by now was much emaciated. I requested the mother to feed the child in my presence, and observed the most criminal carelessness noted above. The same treatment was ordered as on my first visit except the diet. This was to consist of half a teaspoonful of lacto-somatose dissolved in a half glass of hot water every four hours, and nothing else. The child steadily improved from this time on and made an uneventful recovery. I permitted the addition of freshly prepared beef broth to the lacto-somatose after one week.

Case II.—J. W., a girl, aged one year. First visit, May 3d. Surroundings and condition of life bad. Patient had been suffering with bacterial diarrhoea for two weeks without medical attention; she was much emaciated and was having ten to fifteen evacuations daily. Stigmata of congenital syphilis. Temperature, 104° F, and did not fall below 102° F. in the evening for several days. Ordered calomel powders, as in Case I, and gave six baths at ten, six-thirty, and eleven o’clock, with three minims of syrup, ferri iodidi every six hours. No food except sterilized water to be given for the first twenty-four hours, and then half a teaspoonful of lacto-somatose in half a glass of boiled water, still hot. This was to be given every three hours and freshly prepared. At the end of one week the condition of the patient was vastly improved; no fever; bowels almost normal. She was taking lacto-somatose, to which beef broth had been added, with increasing relish, and was also gaining flesh rapidly. The parents took offense because I censured them for administering paregoric to the child to secure quiet for themselves at night, and discharged me. A neighbor has since told me that they began at once to feed the child on milk from the milkman, that it had a relapse almost immediately, and died in a few days.

Case III.—My own child, a boy, aged two years, was attacked on May 27th with symptoms almost choleraic in their intensity. Temperature 104° F. and severe nausea. Gave calomel, about half a grain to a grain, placed on the base of the tongue, as I could get it retained no other way. Administered a tepid bath at intervals of four hours until temperature was reduced to almost normal, which was in about twelve hours. Irrigated bowels with saline solution through soft-rubber catheter every four or five hours until lower bowels were thoroughly cleansed. No food except sterilized water for the first twenty-four hours, and then began the lacto-somatose, as in the former case. Improvement was immediate and marked until the fourth day, when by accident the patient obtained access to some candy, which I have no doubt was dust-covered, and ate heartily of it. The result was a severe relapse, accompanied by a temperature at one time reached 105° F., a bloody mucous diarrhoea, and again intense nausea. Owing to the impossibility of his retaining anything, there were prostration, and excessive temperature, I almost despaired of his life. The calomel was given as before, and mustard applied to the entire abdominal surface. The calomel acted very promptly and the nausea ceased at the same time. Intestinal irritation, tepid baths, etc., were administered as indicated, and lacto-somatose was used as before, and the further convalescence was uneventful, though, owing to the child’s feeble condition, somewhat protracted. In this case.
the lacto-somatose constituted the sole diet for one week, and was taken with increasing relish all the time.

Case IV.—A boy, aged ten months. Called May 31st. Had been suffering with loose bowels for some time (dyspeptic), and had been taken the day before with a very severe diarrhoea with all the symptoms of acute infection. was not weaned, and the mother declared that it had no food except some water, which must have been the source of infection. The child being well advanced in dentition, and the mother’s milk being objectionable both on the general ground that milk is favorable to the growth and development of bacteria, and the further reason that this mother was in very poor health, having occasional diarrhoea with fever, I ordered the child to be weaned, and gave it as a diet lacto-somatose, to which was added after a few days thin gruel and milk sugar. This, with the calomel powders, as in Case I, was the entire treatment, on which the little fellow rapidly improved, and is now the picture of health. The lacto-somatose was given for three weeks.

During the last three months I have treated about twenty-five cases of infantile diarrhoea, many of them of the gravest form, and am well pleased with the results, which are, one death, and complete recovery in all the remainder except two. I have treated them all by substantially the same plan that is described in the four cases. I am especially well pleased with lacto-somatose as a food in these conditions, and am now using it in the first case of typhoid I have met with this season, a condition in which the preparation should be very useful. This food is a preparation of the albumoses of milk with five per cent. of tannic acid in chemical combination.

The following is a summary of my observations on the use of this preparation:

It is readily prepared with hot water.

It forms an agreeable addition to other liquid foods.

It is palatable and is taken with increasing relish.

It is not an irritant to the intestines, but, on account of the combination with tannic acid, assists materially in the treatment of diarrhoea.

It is aseptic, and on account of the method of preparation not liable to be infected.

It contains all the albuminous principles necessary to nutrition, and with slight and judicious additions will support life in all its functions for an indefinite length of time. 1401 East Twelfth Street.

EPILEPTIC EYE STRAIN.

By C. M. CAPPS, M. D.,
KNOXVILLE, TENN.

The only apology I can offer for this paper is the importance of a proper consideration of eye strains and the relations they bear to functional disorders of the nervous system. That errors of refraction do produce a long list of sympathetic neurotic conditions is no longer questioned, and one of the most formidable of these conditions is the one under consideration. The term I use to express this condition, so far as I know, is foreign to medical literature, but it seems to convey the idea admirably. It seems a very logical conclusion that eye strain might produce an epileptic convulsion. When we consider the complicated arrangement of the nerves of the iris and ciliary processes, I do not believe that the direct effort that is made by the eye to produce normal refraction causes an epileptic attack; but the continued effort that is put on the filaments of the nerves of accommodation in course of time sets up a reflex condition of the sympathetic system that produces the paroxysm, just as it does in other organs of the body. Indeed, it seems that the impression on the eye would be the most apt to cause reflex action, as the nervous arrangement of the organ of sight is so complex in its structure that it can distinguish the rays of light even in their length and color. I have reports of but two cases of epileptic eye strain that have come under my observation in the last two years.

Case I.—Miss Z., aged nine years, came under my observation one year ago with this history: Has had epileptic convulsions since four years of age; would have from three to six convulsions every month; was put at school at eight years of age; convulsions became rapidly worse. I diluted the pupil with atropine; the convulsions stopped. The patient had compound myopic astigmatism.

R. = 2.00 = −50, cyl. ax. 90°.
L. = 1.50 = −75, cyl. ax. 90°.

There has been no return of the epilepsy at the time of the present writing.

Case II.—Miss Q., aged eight years, epileptic since she was three years of age. This was a case of compound hypermetropic astigmatism.

R. = +1.50 = +75, cyl. ax. 180°.
L. = +2.00 = +50, cyl. ax. 180°.

These glasses were prescribed five months ago. No return of epilepsy at the present writing. The first that led me to suspect that epilepsy was sometimes caused by errors of refraction was reading reports of cases of epilepsy that were benefited by the administration of belladonna. The good results were only obtained when the systemic effects were produced, and passed off soon after the remedy was discontinued.

It is fair to say that the good results of belladonna in these cases was due only to the power it had to dilate the pupil, and it was lost as soon as the effect passed off. I wish to say that in all cases of epilepsy occurring in children it should be the duty of the family physician to have them see an eye specialist, at least after other remedies have failed.

Ergot in the Sore Throat of Phthisis.—Dr. J. Howe Adams (Medical Times, September) records six cases of phthisis in which the congested pharyngeal "sore throat" was treated by the administration of the fluid extract of ergot in twenty-minim doses three times a day with excellent results, the sore throat subsiding in from three to five days. Ulceration was present in two cases. All the cases but one were those of patients in an advanced stage of phthisis.
GLAUCOMA

FOLLOWING SUPRAORBITAL NEURALGIA
OF MALARIAL ORIGIN.

By Louis A. Bize, A. B., M. D.,
Tampa, Fla.

Mr. J. J. D. came to me June 10th suffering intensely with his right eye. He gave a history of having had a similar attack five years since that lasted some time. Upon examination I found the ball congested and tender on pressure, the cornea steamy and excoriated in two or three spots, the pupil dilated and tension increased. The anterior chamber was somewhat shallower than in the other eye. There was intense pain radiating back over entire right side of the head. I was unable to see the fundus on account of the hazy condition of the cornea and the cloudy condition of the lens. No increased temperature. I diagnosed a glaucomatous condition, although the intense pain was entirely out of proportion to the increased tension and other symptoms. Eserine was instilled and hot applications advised. I saw him next morning and he was somewhat improved, the pupil had contracted and tension was reduced to about normal; a weak solution of eserine was again instilled and hot applications continued. I was sent for again about three o'clock that afternoon, and found the patient suffering intense pain. Upon examining the eye the pupil was again found dilated and tension increased. A hypoplastic of morphine was given, eserine instilled, leeches applied, and heat continued. He rested badly that night, and when seen again next morning was suffering from another attack; upon examination the same condition of affairs was found to exist as before; the same plan of treatment was gone through, with only partial relief; he suffered a great deal all day; the morphine only modified pain. These attacks continued at irregular intervals for several days, and at no time was the tension greater than +1. About the seventh day the attacks began to appear at about the same hour every night. I had used the eserine regularly and was able to reduce the tension; hot applications were continued and bowels kept open. At no time did I think the increased tension sufficient to justify an iridectomy. Notwithstanding the treatment, the attacks returned, and he suffered the most excruciating pain.

The attacks finally occurring periodically caused me to suspect a malarial origin, and I at once commenced the use of quinine in large doses—five grains, combined with one two-hundred-and-fortieth of a grain of strychnine and one grain of capsicum were given every two hours during the day and night, and an hour previous to expected attack ten grains were given. The first night following this treatment the attack was delayed two hours. The next day the same course was pursued, and I was gratified to see him pass through the night without an attack. This treatment was continued, slowly lessening the amount of quinine given; the patient improved daily, and at the end of ten days after the first dose of quinine was discharged, practically cured. I advised daily doses of quinine for a month after discharge.

The Buffalo Academy of Medicine.—At the quarterly meeting, on Tuesday evening, the 12th inst., Dr. Daniel R. Brower, of Chicago, read a paper on The Medical Aspects of Crime.

Therapeutical Notes.

Arsenic and Cinnamic Acid in Tuberculous Disease.
—Hoff, of Vienna, an assistant in von Stollfafa’s clinic (Wiener klinische Rundschau, 1899, Nos. 23 and 24; Medicinisch-chirurgisches Central-Blatt, July 21st), has used a preparation made according to this formula: B: Arsenious acid, 13 grains; Purified potassium carbonate, 3 grains; Cinnamic acid, 45 " Distilled water, 15 " Boil until perfect solution is effected (for three quarters of an hour) and add: Brandy, 38 grains; Aqueous extract of opium, dissolved in thirty-seven grains of distilled water and filtered 45 " S.: Six drops, gradually increased to twenty-two, to be taken after the midday and evening meals. This is used in cases in which there is no hectic.

Ointments for Zoster.—The Gazetta degli ospedali e delle cliniche for July 20th gives the following formula:

1. R. Cocaine hydrochloride, 3 grains; Zinc oxide, 15 " Starch, 150 " M. 2. R. Boric acid, 2 parts; Zinc oxide, 4 " Glycerite of starch, 30 " M.

To Abort a Cold.—Max Nasseran asserts that an incipient cold in the head can be checked if the nose is thoroughly rinsed out with a weak (pale pink) solution of potassium permanganate, which seems to have a specific action upon the germs of Coryza. It checks colds in the first hour or so. After blowing the nose vigorously, both nostrils are well rinsed out with the solution, the fluid being allowed to run out through the other nostril and through the mouth. Each nostril is wiped out with cotton on the finger. A small dry plug of cotton is then pushed well up into each nostril, and the nostrils are filled with the weak solution, with the head held back, the cotton being allowed to soak it up. The plug is left undisturbed for about an hour, when it can be expelled by blowing the nose. Even an established cold is favorably influenced by this treatment, but it is most effective when the sneezing, tickling, and increased secretion announce the onset of the attack.

Practitioner: Cincinnati Lancet-Clinic, August 19th.

An Ointment for Loss of the Eyebrows.—The Riforma medica for July 21st attributes the following formula to Trousseau, but it can hardly mean the famous French professor:

R. Vaseline, 150 grains; Castor oil, 60 " Gallic acid, 15 " Oil of lavender, 8 drops. M.

The Copaiba Treatment of Sciatica.—M. Marchal and M. Glorieux (Presse medicale Belge, July 30th) have reported to the Society of Neurology excellent results from the systemic treatment of sciatica by balsam of copaiba administered in capsules from eight to ten daily.
HERNIA FROM THE LIFE INSURANCE POINT OF VIEW.

To say simply that a man has a hernia is to say very little about what it indicates as to the original tonicity of his abdominal wall or about the likelihood of his having serious trouble from it in the future. But particulars of the case are important, not only to the man himself, but to the life insurance company that is asked to accept him as a "risk." The company's point of view is considered by F. Bayer (Correspondenzblatt des Vereins deutscher Aerzte in Reichenberg, March 15th; Medicinisch-chirurgisches Central-Blatt, July 21st), who takes the stand that hernia is rarely traumatic, that is, occasions purely by an injury, although a person affected with rupture almost invariably avers that it was brought on by a strain. In the cases in which traumatism really is the cause of a hernia, he says, the individual feels a sudden onset of pain, and it may become so severe as to lead him to seek medical aid. It may be accompanied by vomiting. When, however, the applicant goes on to speak of his having gone at once about work incompatible with the existence of such pain, it may be assumed that the hernia was not recent and traumatic. Occasionally, the author adds, a traumatic hernia is accompanied by such external signs as effusion of blood and redness of the skin. Furthermore, the size of the hernial tumor is of importance in settling the question of its traumatic or non-traumatic origin; if an inguinal hernia occasions a swelling larger than a hen's egg or if it has already reached the serotum, it can not be regarded as of recent formation. Also, all herniae that are readily reducible with the person in the upright posture, or are reduced spontaneously on his lying down, are not of traumatic origin and must be regarded as of some standing. Furthermore, it is improbable that bilateral hernia should be produced by a contusion of the abdomen.

In opposition to Hoffmann, for example, the author holds that a hernia should not be looked upon as incurable or as necessarily a bar to active work. The more cases one sees, he remarks, the more one realizes that
a hernia does not preclude the severest work year in and year out, and that without the safeguard of a truss. The danger of strangulation is undeniable, but the occurrence of that accident is rare in comparison with the frequency of hernia. On account of these considerations, he says, the life insurance companies have of late years refrained from insisting on an increased rate for the subjects of hernia. With all our recent advances in surgery, he adds, hernia must no longer be regarded as irremediable, and it should not be so set down save in exceptional instances.

THE FUTURE OF MEDICAL CONGRESSES.

We have never been among those who looked upon huge medical meetings, practically open to all comers, as in the highest degree conducive to the advance of medicine, although we recognize that the volumes in which the proceedings of the great congresses are published are commonly of great value. That spicy commentator on current events the editor of the *Gazette médicale de Paris*, M. Marcel Baudouin, recently made the Amsterdam International Congress of Gynecology the text of some radical remarks concerning medical congresses in general. They seem to have made something of a sensation and to have started a discussion on some of the fundamental features of congresses of medical men. The *Semaime médicale* declares its conviction that these reunions can not survive if they are to be kept open to everybody who chooses to attend, and it would have nobody entitled to take part in the discussions but those who are invited to do so by the managers.

This provision would be an extension to quasi-extemporized and loosely organized bodies of an idea that we have ourselves advocated in the case of societies of permanent organization, but only with regard to non-members. Nothing, in our opinion, is more detrimental to the efficiency and dignity of a medical society than the indiscriminate acceptance of papers volunteered by outsiders. We would even advise the barring of such papers altogether. At the same time we think it in the highest degree desirable that a few non-members who are known to be above axe-grinding should be asked to make addresses, read papers, and take part in the discussions. But can this arrangement be extended to international congresses as those bodies are at present constituted? M. Baudouin (*Gazette médicale de Paris*, August 26th) is convinced that it can not. His argument is a very practical one, and we can see no escape from it. He submits that those who were shut off from participation in the proceedings, merely al-

lowed to be present as auditors, would not accept that meagre privilege; consequently the treasury would suffer and the expenses could not be met. Hence, it seems to M. Baudouin, international medical congresses must in the future, as they have done in the past, keep their doors open to all legally qualified practitioners and allow all such practitioners in attendance to take an active part in the proceedings.

VENereal DISEase AND MARRIAGE.

In its issue for August 31st the *Boston Medical and Surgical Journal* says: "A law recently passed by the Michigan legislature, according to the Medical Record, forbids the marriage of any person suffering from gonorrhoea or syphilis, and provides that any one so diseased who may marry shall be guilty of a felony punishable by a fine of not less than $500 or more than $1,000, or imprisonment in the penitentiary for a term not exceeding five years, or by both fine and imprisonment. A wife or husband may testify against her or his guilty spouse, and the privilege of medical secrecy is also abrogated in such cases." It seems to us that one result of such a senseless law will be to deter the subjects of venereal disease from seeking medical advice, provided they have the remotest idea of marrying.

THE AGNews, CALIFORNIA, LUNATIC ASYLUM.

In our issue for August 5th we spoke of grave charges against the officers of the asylum that were then under investigation, and expressed our conviction that they were not wholly unfounded. We learn by the *Journal of the American Medical Association* for September 2d that the investigation has led the governor of the State to conclude that the medical officer in charge and his assistants should be dismissed at once. It is added that the superintendent not only will not retire, but intends to sue the governor for libel.

THyREOID MEDICATION IN CONGENITAL MYXEDEMA.

An interesting and encouraging case is that of an idiotic dwarf reported by Sklarek (Berliner klinische Wochenschrift, 1899, No. 16; Centralblatt für Chirurgie, July 29th). It was that of a girl who, although seventeen years old, was only about twenty-seven inches in stature and had no more intelligence than a child a year old. She had all of Bournville's characteristics of congenital myxedema. Sixteen months of thyroid medication resulted in a growth of eight inches in stature, with a corresponding gain in weight, and the intelligence of a child three or four years old, besides the subsidence of the physical signs of myxedema.

THE FEVER OF CANCER.

The occurrence of febrile phenomena in cases of carcinoma, quite apart from complications, has often been recognized, but probably its frequency has not been thought to be so great as is shown by Freundweiler (Deutsches Archiv für klinische Medicin, lix; Centralblatt für innere Medicin, August 12th), who has ob-
served it in 117 out of 475 cases. It is seldom continuous, but for the most part remittent or intermittent, although rarely showing the type of malarial fever. In a considerable proportion, nearly twenty-five per cent., of the post-mortem examinations no ulceration was found, and so the author infers that, like tubercle and lymphosarcoma, carcinoma may have a direct pyrogenous effect.

THE SERUM OF THE VACCINATED CALF IN THE TREATMENT OF WHOOPING-COUGH.

For a long time the belief has been entertained that to vaccinate a child was to protect it to some extent against whooping-cough, although only for the time being. Perhaps it was this belief that led a Constantinople physician, Dr. Violi (Archives orientales de médecine et de chirurgie, June; Indépendance médicale, July 26th), to experiment with the serum of the vaccinated calf, which he appears to have administered subcutaneously in cases of whooping-cough. He finds that it mitigates the paroxysms and sometimes eures the patient. He has made some check experiments with the serum of the non-vaccinated calf, but too few to lead him to any settled conclusions.

THE NEW VOLUME OF THE INDEX-CATALOGUE.

The fourth volume of the second series of the Index-Catalogue of the Library of the Surgeon-General's Office, United States Army, carrying the vocabulary from D to Emulsions, has lately been issued. The librarian, Major and Surgeon James C. Merrill, under whose supervision the volume was prepared, is entitled to as much credit as was accorded to the editors of preceding volumes, for in the new one the same carefulness and regard for system are discernible as, fortunately, have prevailed in the entire work.

PRECOCIOUS PUBERTY.

Cases of precocious puberty are not very rare, but they are all worthy of record. Klein, of Bremen-Wolmershausen (Deutsche medicinische Wochenschrift, 1899, No. 3; Centralblatt für Gynäkologie, August 12th), reports the case of a girl who, when ten months old, was returned to her parents, having until then been cared for by strangers. At that time it was observed that her breasts were well developed, her genitals were large and hairy, and she was menstruating. Menstruation was regular for nine months, each period lasting about eight days; then there were four months in which she did not menstruate. After that a haemorrhage set in which lasted seven months, in spite of tonics and even styptics, and then ceased after an attack of measles. The child had been puny for the first six months of her life, and subsequently her general condition was not very good. Her mental development was that proper to her age.

ANTHANTRACIC SERUM IN THE TREATMENT OF MALIGNANT PUSTULE.

The prospect seems good for the triumph of serum treatment over the various forms of anthrax. Abba and Piccardi (Gazetta degli ospedali e delle cliniche, 1899, No. 34; Centralblatt für innere Medizin, August 12th) report a case of malignant pustule successfully treated with Selavo's anthracitic serum, and it is said to be the twenty-seventh case thus far cured by this treatment. They are all stated, moreover, to have been cases in which the disease was progressing. The injunction is added that there should be no delay in resorting to the serum.

UNIVERSAL BIRDS.

Babies born at full term and perfectly developed, although remarkably below the average size and weight, are not very uncommon. Recently the newspapers recorded the birth, in the borough of Queens, of a boy that weighed only a pound and a half. That baby, like others remarkable for diminutiveness at birth, is not unlikely to grow to be a person of ordinary stature.

THE TREATMENT OF TAPEWORM BY IMPORTING IT WITH MORPHINE.

Dr. J. W. Kimle (Medicinie, September) relates the following ingenious and, we believe, original method of dealing with tapeworm. It is well known that after the administration of tannic acid a large part of the body protrudes, but the head reattaches itself lower down in the intestine. The author, having to deal with such a case, tied a string moderately tightly around the protruding portion of the worm about three inches below the patient, and then injected into the substance of the worm above the ligature half a grain of morphone, which, being taken up by the longitudinal vessels, would circulate throughout the worm. The protruding part was then severed below the ligature, and the remainder returned to the bowel. After about ten minutes a large injection of water was given, when the whole of the upper portion came away, apparently dead. The author has twice used this method successfully, and it seems to deserve a wide trial.

"CHRISTIAN SCIENCE" IN ILLINOIS.

It is announced that the attorney-general of Illinois has given an opinion to the effect that the treatment of the sick by "Christian Science" and other like methods is not illegal, provided no medicine is used. The "Christian Scientists" will doubtless exult at this, but it may prove ultimately a stumbling-block in their way, for it will detract from their attitude as martyrs.

ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending September 9, 1899:

Marine-Hospital Service Health Reports.—The following cases of small-pox, yellow fever, cholera, and plague were reported to the surgeon-general during the week ending September 8, 1899:

Small-pox—United States.
San Francisco, Cal., July 31..... 5 deaths.
Jacksonville, Fla., Sept. 2..... 1 case.
Louisville, Ky., Aug. 31..... 2 cases.
Cleveland, Ohio, Aug. 26-Sept. 2..... 4 cases.
Altona, Pa., Aug. 26-Sept. 2..... 2 cases.
Texas, six towns in State Aug. 26 and Sept. 2..... 71 cases.

Small-pox—Foreign.
Antwerp, Belgium, Aug. 19..... 1 case, 1 death.
Bahia, Brazil, July 29-Aug. 7..... 3 cases, 1 death.
Rio de Janeiro, Brazil, July 21-Aug. 1..... 55 cases, 22 deaths.
Athens, Greece, Aug. 19..... 7 cases, 2 deaths.
Bombay, India, Aug. 2..... 6 cases.
Chihuahua, Mexico, Aug. 26..... 3 cases.
Nuevo Laredo, Mexico, Aug. 26..... 1 case.
Moscow, Russia, Aug. 11..... 2 cases, 2 deaths.
Odessa, Russia, Aug. 12-15..... 11 cases, 3 deaths.
St. Petersburg, Russia, Aug. 19..... 3 cases, 1 death.
Warsaw, Russia, Aug. 12..... 1 case.
Strait Settlements, Singapore, July 15..... 2 deaths.

Yellow Fever.
Bahia, Brazil, July 29-Aug. 12..... 3 cases, 2 deaths.
Rio de Janeiro, Brazil, July 21-Aug. 1..... 20 cases.
Panama, Colombia, Aug. 18..... 1 case, 1 death.
Port Limon, Costa Rica, Aug. 18..... 1 case.
Christo, Cuba, Aug. 19..... 1 case.
San Cristobal, Cuba, Aug. 24..... 2 cases.
Key West, Fla., Sept. 8..... 7 deaths.
New Orleans, La., Sept. 2..... 2 cases, 1 death.
Tampico, Mexico, Aug. 21-28..... 9 deaths.
Vera Cruz, Mexico, Aug. 25-31..... 19 cases, 14 deaths.
San Salvador, Salvador, Aug. 1..... 2 cases.

Cholera.
Bombay, India, Aug. 1-8..... 2 cases.
Calcutta, India, July 22-29..... 55 cases.
Osaka and Higo, Japan, Aug. 12..... 4 cases, 1 death.

Plague.
Amar, China, July 22..... 250 deaths.
Amar, China, July 22-29..... 100 cases.
Amar, China, July 29-Aug. 5..... 75 cases.
Hongkong, China, July 22-29..... 37 cases, 59 deaths.
Alexandria, Egypt, Aug. 7-13..... 46 cases.
Bombay, India, Aug. 1-8..... 75 cases.
Calcutta, India, July 22-29..... 16 cases.
Tsamui, Formosa, July 26-Aug. 10..... 13 cases, 20 deaths.
St. Petersburg, Russia, Aug. 12-21..... 1 case.
Strait Settlements, Penang, July 14-21..... 49 cases, 59 deaths.
Strait Settlements, Singapore, July 13-22..... 3 cases, 5 deaths.

Changes of Address.—Dr. E. Danziger, to No. 2022 Madison Avenue, New York; Dr. Charles P. Noble, to No. 1309 Locust Street, Philadelphia.

Army Intelligence.—Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from September 2 to September 9, 1899:

Balch, Lewis, Major and Surgeon, United States Volunteers, will proceed to San Francisco for duty.
Borden, William C., Captain and Assistant Surgeon, is detailed as a member of the examining board convened at Washington Barracks, vice Lippitt, William F., Jr., Major and Surgeon, relieved.
Fowler, E. W., Acting Assistant Surgeon, United States Army, will proceed to United States Military Hospital No. 1, Havana, Cuba.

Harvey, Philip F., Major and Surgeon, is detailed as a member of the examining board at San Francisco, vice Mosley, Edward B., Major and Surgeon, relieved.

Higgins, Aubray F., Acting Assistant Surgeon, will report for duty with Siege Battery K, Fifth Artillery, en route from Fort Hamilton to Montauk Point, Long Island.

Kemp, Franklin M., First Lieutenant and Assistant Surgeon, United States Army, is granted leave of absence for seven days.

Kimball, James F., Major and Surgeon, is granted leave of absence for one month.

Maclean, Donald, J., Acting Assistant Surgeon, will proceed to Honolulu, Hawaiian Islands, for duty with the battalion of the Sixth Artillery.

Matthews, W. S. H., Major and Brigade Surgeon, is assigned to duty on the transport Warren during the voyage to the Philippines, and, upon arrival at Manila, will report to the commanding general for instructions.

Waterhouse, S. M., First Lieutenant and Assistant Surgeon, will report to the commanding officer, Fort Columbus, New York, for temporary duty.

Naval Intelligence.—Official List of Changes in the Medical Corps of the United States Navy for the Two Weeks ending September 9, 1899:

Chaffee, J. F., Assistant Surgeon. Detached from the Boston and ordered home to await orders.

Decker, J. C., Surgeon. Detached from the Monadnock and ordered to the Monocacy.

Stoughton, J., Passed Assistant Surgeon. Detached from the Monocacy and ordered to the Monadnock.

Ward, B. R., Passed Assistant Surgeon. Detached from the Boston and ordered home to await orders.

Society Meetings for the Coming Week:

Monday, September 15th: New York Academy of Medicine (Section in Ophthalmology and Otology); Hartford, Connecticut, Medical Society; Chicago Medical Society.

Tuesday, September 16th: New York Academy of Medicine (Section in General Medicine); Buffalo Academy of Medicine (Section in Pathology); Ogdensburg, New York, Medical Association; Syracuse, New York, Academy of Medicine; Medical Societies of the Counties of Kings and Westchester (quarterly), New York; Baltimore Academy of Medicine.

Wednesday, September 17th: Medico-legal Society, New York; Northwestern Medical and Surgical Society of New York (private); New Jersey Academy of Medicine (Newark).

Thursday, September 18th: New York Academy of Medicine; Brooklyn Surgical Society; New Bedford, Massachusetts, Society for Medical Improvement (private); Medical Society of City Hospital Alumni, of St. Louis; Atlanta Society of Medicine.

Friday, September 20th: New York Clinical Society (private); New York Society of German Physicians; Yorkville Medical Association, New York (private); Philadelphia Clinical Society; Philadelphia Laryngological Society.
Births, Marriages, and Deaths.

Baker—Beyer.—In Stapleton, New York, on Sunday, September 3d, Captain George Livingston Baker, Jr., United States Army, and Miss Magdalene Beyer, daughter of Dr. Herman Beyer.

Fox—Robinson.—In New York, on Tuesday, August 15th, Dr. Charles T. Robinson and Miss Marie Nathalie Fox.

St. Martin—Maurin.—In New Orleans, on Tuesday, September 18th, Dr. J. V. St. Martin and Miss Lyllyan Maurin.

Died.

Ludlow.—In Bridgehampton, New York, on Tuesday, September 5th, Dr. George Floyd Ludlow, in the twenty-ninth year of his age.

Nolen.—In Franklin, Massachusetts, on Monday, September 4th, Dr. William B. Nolen, in the eighty-third year of his age.

Robinson.—In New York, on Monday, September 11th, Dr. Charles T. Robinson, in the twenty-seventh year of his age.

Letters to the Editor.

Constriction of the Penis.

415 Warren Street, Brooklyn, N.Y., August 21, 1899.

To the Editor of the New York Medical Journal:

Sir: A dangerous practical joke was exemplified in the case of a man who, about 6:30 a few mornings since, called at my house and stated that his was probably the most peculiar case I had ever seen. I had heard that remark often, so did not give it much attention, but I noticed the man was thoroughly alarmed. I had hardly closed the office door when he had his trousers down and said: “I had that on my ring finger when I went to bed, and you can see where it is now.”

I saw on his penis, as close to the body as it could be crowded, a very heavy plain gold ring. The penis was swollen to the fullest size at erection, as black as coal, and as cold as a stone. The ring was so imbedded in the swollen tissues that I did not think it could be cut or filed off, and, as the organ was so discolored and cold, I doubted if it could be revived if the ring was removed. My first impulse was to send him to hospital for amputation, but I decided to try to cut the ring. With a small napkin I held the tissues back and with a knife-filed flat quartering across the ring (it was so close to the body I could not file straight across), and when I had nearly filed through with considerable trouble I succeeded in getting a director under the ring, and then, after a full hour’s work, I succeeded in cutting it through. I then took two tooth forceps and, grasping each severed end, opened the ring. As soon as I did so the urine started and the fellow was greatly relieved. I immediately placed the organ in hot water to which I added some ammonium chloride and, placing a kettle of boiling water near, told him to keep adding the hot water so as to keep the solution as hot as he could possibly bear it. In about an hour there was some improvement in the color of the penis, and I dressed it with a liberal amount of cotton saturated with five-per-cent. solution of ammonium chloride and told him to come back at noon. At noon the color was coming back, but there were two blebs near the glans. These I lanced and then was able to draw the foreskin over the glans. Then for the first time I told him he would be all right. I have not seen him since, so I think he must be well.

So far as his story goes, evidently the ring was slipped over the penis simply as a joke, with no intention of injury or harm to him. He had taken a long bicycle ride, drank several glasses of beer, and gone to sleep, dead to the world, till the pain awoke him.

Charles F. Wright, M.D.

The Law in Its Relations to Physicians.

By Arthur N. Taylor, LL.B.

CIVIL MALPRACTICE, INCLUDING GENERAL LIABILITY OF PHYSICIAN TO PATIENT.

(Continued from page 382.)

To whom Liable.—To whom the physician becomes liable by reason of negligence or malpractice is often a question that would confuse one not understanding the fiction of the common law upon which these rights are often based.

At common law the family formed a legal unit, which was represented by the husband and father. An injury to his person was one which created a cause of action in his favor alone and upon which he alone must sue; but should the injury be done to the wife, a double cause of action arose—one in favor of the husband for damages for the loss of her services and society during the time she was suffering from the injury, also for the cost of nursing and caring for her while ill. The other cause of action arose in favor of the wife for the injury inflicted upon her, in which the measure of damages was an amount adequate to compensate her for the inconvenience and suffering caused thereby. In this cause suit must be brought by the husband and wife jointly. In case of injury to the child, the rule is nearly the same. A cause of action arises in favor of the father for the loss of the child’s services and for the cost of curing and caring for him. A separate cause of action arises in favor of the child for the personal injury which he has sustained and for the suffering to which he has been thereby subjected, and for any permanent injury reaching beyond his minority; upon this cause of action suit is brought for the infant by his guardian, or by a third person, who is styled the next friend or prochein ami. The father, if living, usually does, and by natural right may, appear for the infant as next friend.

In cases where the cause of action is made to survive the injured party by statute, the statute usually provides by whom the suit shall be brought and prosecuted, and in all such cases its provisions must be strictly followed.

Liability for Act of Partner.—As a general rule of law, each partner in a copartnership is bound by the acts
of his copartners performed in the scope of the partnership business.

This law has been held to apply where a patient employed a firm of physicians to treat a broken leg. Both members of the firm attended him. The treatment of one was skillful and proper, but the treatment of the other was negligent and unskillful. Suit was commenced against both, and the court held them to be equally amenable.*

**Effect of Judgment against Patient for Fee upon Suit by him for Malpractice.**—Although the effect of a judgment obtained by a physician against a patient for his fee in a given case upon a cause of action for malpractice in that particular case has already been treated,† it is thought advisable to refer to the subject again at this point.

Should a physician begin a suit, say before a justice of the peace, to recover the value of his services in a given case, and the defendant appears and defends upon the grounds that the services were valueless and that he sustained injury from the physician's negligence, etc., and a judgment is rendered in favor of the physician, this judgment, if unrepealed, stands as a complete adjudication of the patient's cause of action for damages, and will prevent him from subsequently bringing suit against the physician in another or higher court to recover damages. But supposing the patient does not appear, but suffers judgment to be entered against him by default, or supposing he appears and defends upon other grounds than those of the physician's negligence or incompetence; what, then, is the effect of a judgment for the physician? This is a question upon which the courts of different States differ. Those of Indiana, Iowa, Ohio, and Wisconsin‡ hold that such a judgment will not prevent the patient from afterward suing the physician to recover damages sustained by reason of his negligence or incompetence. Upon the other hand, the courts of New York, New Jersey, and West Virginia§ hold that a judgment in behalf of the physician for his fees in a particular case is a complete bar to an action by the patient for damages sustained by him from improper treatment of the physician in that case, whether in the defense the character of the professional services rendered is subject to adjudication or not. Nor is the judgment in behalf of the physician for his fees the less efficacious because the suit in which it was obtained was begun before a justice of the peace after suit was commenced in a higher court by the patient to recover damages against the physician for negligent treatment in the particular case.||

In those States in which the courts have not passed upon this question it must be considered an open one.

---

* Whitaker v. Collins, 54 Minn., 299.
† See chap. vi, Recovered of Compensation, MS.
|| In West Virginia the court goes only so far as to hold that the judgment obtained by the physician for the amount of his fees is a bar to an action by the patient for malpractice in that case, where the patient appeared generally in the suit instituted by the physician. Had the judgment of the physician been obtained by default, or had the patient appeared specially to plead in abatement to the action, then he would not be precluded thereby from maintaining an action of malpractice against the physician. Lawson v. Conway, 37 W. Va., 159.

---

**Of Proving Malpractice.**—In a former chapter of this work it has been stated that the implied contract of the physician is not that he will cure or even benefit his patients, but simply that he will use ordinary skill and diligence in that behalf; and the preceding pages of this chapter have shown that the physician's liability to a patient can not be predicated upon the mere failure of his skill to benefit the patient, or upon the mere fact that the patient has become worse under his treatment, but that such liability must be founded upon incompetency, unskillfulness, or negligence shown in the treatment of the particular case, from which unprofessional treatment injury has resulted.* It therefore follows that, in an action brought to recover damages resulting from malpractice, proof of the mere fact that a fractured leg is shorter after healing does not amount to *prima facie* evidence of want of skill or care in the surgeon who attended the same.†

Justice Lyon, of the Wisconsin supreme court, in commenting upon the danger of receiving conditions as evidence of improper treatment, said: "The sad thought, 'it might have been,' forces itself upon all in hours of sorrow and gloom; but, unless the thought is verified by substantive and reasonably conclusive proof, it furnishes no safe basis of judicial judgment.

"It is a frequent occurrence that patients change their physicians; also, that the second physician called disapproves the treatment of his predecessor, and changes it, perhaps properly, and the patient dies. In such a case, if it should appear that the practice of the physician first called was incorrect, there is always room to conjecture that had the patient been properly treated in the first instance he would not have died. And yet, if a verdict based upon mere conjecture could be sustained, holding the physician first employed guilty of causing the death of the patient, the practice of medicine and surgery would be most perilous callings. The law does not subject the members of those or any other professions to any such peril." †

And so, where an oculist operated upon a girl of seven years, who had been cross-eyed for some years, for the purpose of straightening her eye, and the evidence showed that he performed the operation in the usual and approved manner, and bandaged the child's eyes and gave directions for her future treatment, other evidence will be required upon which to base a verdict against the oculist than that the child lost the sight of the eye after the operation. To justify such a verdict there must be evidence showing a want of the requisite skill, knowledge, or care on the part of the oculist. The court, on review of this case, said: "We feel certain that a verdict in favor of the plaintiff was not authorized by the evidence, and we believe that sympathy for the plaintiff unduly influenced the jury in rendering such a verdict."

---

* Wurdeman v. Barnes, 92 Wis., 206.
† Filer v. Hughes, 10 Iowa, 579.
‡ Gores v. Graff, 46 N. W. Rep., 48 (Wis.).
|| Sims v. Parker, 41 Ill. App., 384.
there was a slight swelling or protuberance at the point where he located the pain, and that the defendant adjusted the bulb of the truss over this. When the truss was taken off at the end of two weeks this swelling had increased and developed into an abscess. The physician who attended the plaintiff for the abscess was unable to say whether there was an injeptic abscess at the time the truss was first adjusted or whether the abscess was produced by the truss.

The fair conclusion from the evidence given by the experts was that there was no rupture on the plaintiff. It was also shown that it is very difficult in certain cases to tell with certainty whether there is in fact a hernia or not, particularly in the case of fleshy persons.

There was also evidence that tended slightly to show that the abscess was caused by the pressure of the truss, but there was no evidence that the defendant was negligent or unskilful in his diagnosis or in fitting the truss.

This evidence was held to be insufficient to warrant a verdict for the plaintiff. The court said: "Proof that he was mistaken as to the existence of a rupture, or that the abscess was caused by the pressure of the truss, was not enough to entitle plaintiff to a verdict. "Proof of a bad result or of a mishap is of itself no evidence of negligence or lack of skill. The defendant is qualified to practise medicine and surgery, and the evidence of the experts in his profession show him competent and skilful. Before a recovery could be had against him it must be shown that his treatment was improper or negligent, not merely that he was mistaken or that his treatment resulted injuriously to the plaintiff. A physician or surgeon, or one who holds himself out as such, is only bound to exercise ordinary skill and care in the treatment of a given case, and in order to hold him liable it must be shown that he failed to exercise such skill and care."

"The jury can not draw the conclusion of unskilfulness from proof of what the result of the treatment was, but that the treatment was improper must be shown by evidence."

From this and the preceding cases it may justly be inferred that the burden of proof is always upon the party attempting to show that the physician has been guilty of lack of skill or of want of care. This has been held to be the law in a number of cases, whether the question arises in a suit against the doctor for malpractice, or whether the issue is raised in a suit begun by the doctor against his patient for the recovery of fees, and incompetence and negligence are pleaded by the defendant as a defense to the action.

The general rule regarding the burden of proof is very well stated by Justice Mayham as follows: "The burden of establishing affirmatively either want of ordinary skill, or a failure to use his best skill, or some negligence in the care or attention of the plaintiff's case, which resulted to her injury, must be met before she can recover."

And so in a case where the patients had sustained a Pott's fracture and the physician, so the evidence seemed to indicate, diagnosed and treated it as a fracture of both bones at a point about five inches above the ankle, the court held there was no evidence upon which to sustain a verdict of damages for permanent injury by stiffening of the ankle joint. In this case an expert witness introduced by the plaintiff stated, on cross-examination, that he recognized the fact as an expert witness that a Pott's fracture will probably leave the joint in a permanently inferior condition, even when the very best surgical skill is employed, and is employed at the most opportune time, and under the best circumstances. In answer to the question, "You are not prepared to say to the jury that the present condition that the plaintiff presents is due to the fact of what he says in regard to the treatment he received at the hands of Dr. — ?" the expert replied, "I have not said it."

The court said: "It seems to us, therefore, that the case is absolutely barren of any evidence from which it may be inferred that the permanent injury which the plaintiff would suffer had come from any neglect or want of skill on the part of the defendant."

But what is the character of proof required by the courts to fix liability upon the physician for the unfortunate results attending his treatment?

The case of Pettigrew vs. Lewis et al. is instructive upon this point. The plaintiff had undergone an operation for strabismus. The evidence given by the plaintiff was that prior to the operation her eye was strong and in good condition, except as to the affection for which it had been treated; that the operation was successful in straightening the eye, but that afterward neither eye was as strong as before; that some time after the operation she had "a spell of sore eyes"; that the lids were afterward inflamed and her "eyes watered" when she went out in the wind or cold; that she found on attempting to use her eyes that they were weak, and that it was necessary to bring objects close to her in order to see clearly. This, it seems, is about the extent of the evidence offered on behalf of the plaintiff. The supreme court, in reviewing the case, discourses very comprehensively upon the character of evidence required in such a case to fix liability upon the physician. The following liberal extract is therefore taken from the opinion:

"To maintain her action, the plaintiff should have offered evidence of skilled witnesses to show that the present condition of her eyes was the result of the operation, and that it was unskilfully and negligently performed. 'This evidence must from the very nature of the case come from experts, as other witnesses are not competent to give it, nor are juries supposed to be conversant with what is peculiar with the science and practice of the professions of medicine and surgery to that degree which will enable them to dispense with all explanations.'"

"The question whether a surgical operation has been unskilfully performed or not is one of science, and is to be determined by the testimony of skillful surgeons as to their opinion, founded either wholly upon an examination of the part operated on, or partly upon such examination, and partly on information derived from the patient; or partly on such examination, partly on such information, and partly on facts conceded or proved at the trial; or partly on such examination and partly on facts conceded or proved at the trial." It would have been easy for the plaintiff to have submitted to an examination by an experienced physician or oculist capable of determining whether the condition of her

* Chase vs. Nelson, 39 Ill. App., 53; Robinson vs. Campbell, 47 Ill., 625.
† Winner vs. Luthrop, 67 Hun, 511.
‡ Pettigrew vs. Lewis et al., 46 Kan., 78, 26 Pac. Rep., 458.
§ Tefft vs. Wilcox, 6 Kan., 46.
¶ McClell. Mal., 304.
eyes was the result of the operation, and whether that operation was performed with reasonable skill and care. Cases may arise where there is such gross negligence and want of skill in performing an operation as to dispense with the testimony of professional witnesses; but not so in the present case. It is not conceded or proved that the weakness of her eyes had materially resulted from the operation; and even if it was the question would still arise, was she in a fit physical condition to undergo the operation? Did the defendants, before beginning the operation, make due examination to determine her condition and the necessity for an operation? Was the operation performed in a careful and skillful manner? What was the standard of professional skill and scientific knowledge required of these men in that locality? Was the after-treatment and the directions given for the subsequent care of the eye such as would meet the approval of the profession in its present advanced condition? If a mistake was made, was it a case of reasonable doubt or uncertainty or a mere error in judgment, for which there is no responsibility? It was the duty of the defendants to exercise ordinary care and skill; and, this being a duty imposed by law, it will be presumed that the operation was carefully and skillfully performed in the absence of proof to the contrary.*

Exceptions.—It will be observed that in the foregoing statement the court says: "Cases may arise where there is such gross negligence and want of skill in performing an operation as to dispense with the testimony of professional witnesses." This, in other words, means that cases may arise in which a presumption of unskilfulness or negligence on the part of the physician will arise from the condition in which such treatment has left the patient. Such a case, it will be clearly seen, forms an exception to all of the rules above laid down for proving negligence and incompetency. A recent Minnesota case appears to illustrate this exception. In this case, however, the evidence is so meagrely stated in the report that it can not be determined with certainty whether the opinion of the court was based upon the mere condition of the patient or whether there was evidence before it of particular acts of negligence or unskilfulness which the record fails to disclose. The case was as follows: The patient had suffered a miscarriage, having been delivered of a five-months-old fetus. The physician removed the placenta, but in so doing permitted a piece of it about two inches long and two thirds of an inch thick to remain; blood poisoning and a septic condition of the patient ensued from which her left leg became gangrenous, necessitating amputation. Whether there was any evidence offered showing that the defendant's treatment was improper may be reasonably doubted from the report of the case, wherein the court, upon this question, simply says: "Unexplained, the evidence was sufficient to justify the conclusion that the defendant, in the exercise of that degree of care and skill which the law exacts of a physician, might and ought to have reasonably discovered and removed the remnant of the afterbirth."† A proper deduction from this seems to be that the condition of the patient bespoke improper professional treatment, which it became incumbent upon the defendant to explain; thus forming an exception to the general rule prescribed for proving the physician's liability.

Another case which seems clearly to be an exception to the rule is that of Lewis vs. Dwinell,* in which the defendant, after repeated examinations, informed the plaintiff that she was "all right," notwithstanding she had sustained a serious rupture of the perinaum. Upon the question of the defendant's liability as shown from the evidence and from the plaintiff's condition, Justice Haskell said: "If the defendant knew of the rupture and concealed it from the plaintiff, neither taking measures for its repair or relief himself nor giving an opportunity for other professional skill to be employed, little can be said in his excuse. But if the defendant neither discovered the lesion nor had any knowledge of it, a different question arises: Was he professionally negligent in his examinations? He was a physician of seven years' practice, a graduate of Boston University, and must have possessed the ordinary skill and learning required in such cases. His failure then to discover, after repeated examinations, the serious injury from which the plaintiff was suffering, must be held to be actionable negligence. Reasonable attention from a physician of ordinary intelligence would have discovered so palpable an injury."‡

Upon the trial of a suit for damages resulting from malpractice, the liability of the physician is a matter to be passed upon by the jury, aided by the evidence of expert witnesses, who are supposed to enlighten them upon all matters of professional knowledge involved in the case, and guided in their deliberations by instructions from the trial judge upon the law applicable to the questions before them.

Pith of Current Literature.

The Cure of the Intractable Diarrhoea of Weaning by Suppression of Milk from the Dietary.—Dr. R. Saint-Philippe, of Bordeaux (Indian Medical Record, July 19th), says that it is the custom to speak of children as attacked with gastro-enteritis. In his opinion it would be more correct to call it gastro-intestinal dyspepsia, for the digestion is disordered and the diarrhoea is the result. The abdomen is swollen, soft, flabby, and without pain; sometimes it is tense, hard, and painful, and the lymphatics and glands are affected. Returgitations and vomiting are frequent. The motions are furtid, liquid, or puttylike; much more frequent by day than by night. The liver is swollen and sensitive to touch; emaciation progresses; the cachexia deepens, and the shadow of a coffin looms before the eyes of the physician and of the family, now really and justly frightened.

It is under these circumstances and to remedy this evil that well-established custom ordains that we should prescribe a diet of milk, either mixed or plain. It is against this custom, bad in his opinion, that the author desires to raise his voice and to adduce proofs. In such a case, milk is not only useless, it is injurious. It keeps up the trouble. He has observed this fact sufficiently often to make this contrary assertion without hesitation. The author refers to cases in which this diarrhoea existed and the infants were given milk, and more milk, and nothing but milk, the diarrhoea continuing, however, and getting worse. But the cessation of milk food with return to an ordinary and carefully progressive diet,
accompanied by certain prescriptions, hygienic and medicinal, were sufficient to change the whole condition of affairs. The stools diminished from day to day and lost their foul appearance and smell, color returned to the face, and the child became merry and bright and gained weight.

We must not forget, says the author, the fact that milk does not come as a panacea to all digestions. Many adults prove this sufficiently. In order to tolerate and digest milk, it is, above all, necessary that the secretion of pepsin should be normal. Admitting that the milk is irreproachable in every respect, still it is necessary that it is accepted by the stomach and intestines and that it undergoes, thanks to their secretions, all the necessary metamorphoses to cause it to be absorbed by the organism.

The author treats these cases by stopping absolutely and completely the administration of milk and milk foods and restoring nourishment suitable to the infant—at first dejectments of the starch of cereals, water containing egg albumen, weak tea, weak coffee, with plenty of sugar, malt, or Alet or Vals water, sweetened with small quantities of "syrup of punch." Skin friction, by exciting the action of the skin, is useful; the action of the kidneys must be regulated and dyspepsia must be combated. Hot salt baths, injections of artificial serum, and inhalations of oxygen are needed to restore health; but above all things the discontinuance of milk the author deems essential.

Ovarian Pregnancy.—At the Third International Congress of Gynecology and Obstetrics, recently held in Amsterdam, Mlle. Catharine van Tussenbroek, of Amsterdam (Lancet, August 19th), said that the specimen which was the object of the demonstration was obtained by an operation of Professor Kouwer, of Utrecht. The case was one of hemorrhage into the peritoneal cavity with all the characteristic clinical symptoms of ruptured ectopic pregnancy. The patient was thirty-one years of age, the mother of five children, and was in good health until the moment of the catastrophe. Her last menstruation was six weeks previously. The diagnosis of ruptured ectopic pregnancy was made and laparotomy was performed at once. As soon as the abdomen was opened a great quantity of dark-colored blood gushed forth. The patient was brought into Trendelenburg's position. The uterus proved to be soft and somewhat enlarged. The left ovary and tube were normal; at the right ovary was found a tumor as large as a walnut, to which blood clots adhered. The right ovary and tube were removed. The tube was quite normal; the fimbriae were somewhat conglutinated, but the lumen was free. Pathological adhesions between the ovary and the tube did not exist. The tumor and the ovary showed near the top the place of rupture, from which a ruddy fringe came forth. After being hardened the specimen was opened by a median section going through the fringed opening. By this section the gestation sac in the tumor was cut in two halves and an embryo appeared of about twelve millimetres in length, fixed by a short and thick umbilical cord. Microscopical inspection left no doubt that the case was one of ovarian pregnancy. Microscopical investigation showed that the impregnated ovum had developed within a Graafian follicle. That was proved by the fact that the wall of maternal tissue which surrounded the ovum showed the structure of the ruptured Graafian follicle—the well-known corpus luteum. Decidual transformation of the connective tissue in the ovisac was nowhere to be found. The feetal elements were quite the same as in normal uterine placenta. The feetal villi showed the plump and irregular forms which belonged to this early stage of pregnancy. Their epithelial investment consisted of two layers—Langhans's cells and the syncytium. The latter was in many places ciliated. The conclusions which Mlle. van Tussenbroek came to were as follows: 1. Ovarian pregnancy was a fact. 2. Ovarian pregnancy meant pregnancy in a Graafian follicle. 3. The wall of the pregnant Graafian follicle not being transformed into decidua tissue they must conclude that for the implantation of the ovum Webster's decidual reaction was not a condition sine qua non. 4. One piece showing a regular development of characteristic syncytium, they had a new and incontestable proof that syncytium had nothing to do with uterine or tubal epithelium and was an offspring of the feetal ectoblast.

Locomotor Ataxia and Syphilis.—Dr. Albert S. Ashmead (Journal of the American Medical Association, September 2d), referring to a statement that "Professor Erb, from his researches in one thousand cases, believes that 'tabes' (locomotor ataxia) is almost without exception due to syphilis," asks how Professor Erb would explain the fact that in Japan, where syphilis has scourged the population for thirteen hundred years, locomotor ataxia is unknown. In a venerable clinic of ten thousand cases Dr. Ashmead did not find a single case of locomotor ataxia, nor did he meet a native physician who knew of such a disease as "tabes." Opposed to this diagnosis of Professor Erb, says the author, in Germany there stands that of Professor Virchow, who believes that syphilis has no relation whatever to locomotor ataxia.

Upon this the editor of the Journal comments as follows: "Apropos of the above from Dr. Ashmead, we quote the following abstract from the August number of the Journal of Nervous and Mental Disease, referring to a paper on Tabes Dorsalis und Syphilis, by A. Guttman (Zeitschrift für klinische Medicin, 35, 1898, p. 242) : 'The reaction, evident of recent years, against the view of the aetiological significance of syphilis in tabes is made more pronounced in the statistics of the author. In all, some one hundred and thirty-six cases of tabes were closely studied, and of these, deducting six doubtful cases, 38.6 per cent. had had syphilis, while 71.4 per cent. were distinctly nonsyphilitic.' The author also considers the evidence derived from the fruitfulness of syphilitic medication, and gives his approval of the general methods used to strengthen the body—baths, massage, and electricity."

Typhoid Fever in the Insane.—Dr. George Boody, of the Iowa Hospital for the Insane (Journal of the American Medical Association, September 2d), in a paper on Typhoid Fever presented to the association's meeting at Columbus, arrives at the following conclusions: 1. Cases of inverted typhoid fever are comparatively rare, and the subject is deserving of thorough investigation as often and wherever an epidemic occurs, with the object in view of determining the relative frequency of the disease; and in doing this all the methods for confirming this diagnosis should be rigidly applied in each suspected case. In these two epidemics it occurred but once in forty-three cases.

2. Of the patients who recovered, twenty-five per
cent. showed marked improvement in nutrition and muscular strength, while the raminine seventy-five per cent. only reached their former condition in these respects. Compared with previous observations it would seem that insane patients with typhoid fever do not show a degree of improved nutrition after recovery as do those without the mental complications. The patients who improved mentally showed a corresponding favorable change in nutrition, and those whose mental status returned to normal made the most striking changes in this direction. This may not be true, except for these two epidemics, but in them is beautifully illustrated the profound influence that the mind exercises over the processes of nutrition and assimilation.

3. Of this number, 16.6 per cent., all dementias, seemed brighter mentally but relapsed as soon as convalescence was completed, except one case which continued some time longer; 2.77 per cent., all melancholias, made partial recovery and one is just fairly able to resume the ordinary duties of life; 5.56 per cent., one a case of catatonia and one of acute mania, regained completely their former mental status. The behavior of the cases of dementia would lead one to think the fever had some slight influence upon the mental condition, but it is of no value, since the relapse occurred so soon. Such cases are always beyond the possibility of recovery. The prognosis in melancholia is favorable for some improvement, and it is only fair in this one case to assume that the fever played no important rôle in the partial recovery, since the change was no more than was predicted previous to the fever. The prognosis for recovery in acute mania is generally favorable; and in this case it was regarded as specially hopeful some time before the attack of typhoid. The recovery was rapid and complete and took place at about that period in the course of the mental disturbance at which a change might be expected had he not had the fever, hence one would not be justified in giving to the latter any prominence as a curative factor in connection with the insanity.

The Therapeutic Principles Underlying the Treatment of Typhoid Fever.—Dr. L. F. Roush (Journal of the American Medical Association, September 24), in a paper read before the Columbus meeting of the American Medical Association, says that an experience founded on the treatment of a hundred and forty-three cases in the last four years has taught him the value of certain remedial measures about which he can not be mistaken.

First Therapeutic Principle.—The bowels must be acted upon by cathartics. Calomel is the best; from two to six grains once a day for the first six or eight days. Give it, diarrhoea or no diarrhoea: if no diarrhoea, to prevent it; if diarrhoea, to cure it. The typhoid stool must be changed to a bilious stool, or at least to a stool with little odor. It should be always given at any stage for the diarrhoea which has the typhoid stool, but be observant enough to know when you have the action of your medicine, and do not confound the free action from the calomel with diarrhoea, or the diarrhoea with the action of the calomel. You can combine sodium bicarbonate or salol with the calomel if you desire.

The second agent is salicylate of ammonium or sodium. Dr. Roush prefers the ammonium, as it agrees better with the stomach, and is probably more of a stimulant to the heart, and possibly to the secretions and excretions. Five grains every two hours is the average dose, continued night and day, while fever remains above 102° F. in the evening; when it falls below, then only during the day. This is continued from first to last. If it disagrees with the stomach, add aromatic spirits of ammonia or spirits or compound tincture of cardamoms. Sometimes it disagrees at first, but it will not continue to disagree after the first three or four days.

"What is the effect of this combined treatment?" asks the author. In four days, usually, but scarcely ever later than the end of the fifth day, the fever is permanently lessened, the patient comfortable, the pulse full and not fast, no tympanites, the skin and tongue moist; he sleeps at night, is not sick; you would scarcely know he had fever if you did not use the thermometer. He goes on in the same way to the tenth, twelfth, fourteenth, sixteenth, and sometimes to the twenty-first day, but rarely so long, and is free from fever, is convalescent. This usually occurs about the eleventh to the sixteenth day.

But some other measures are to be mentioned. All the water the patient wants, all the tea or coffee he may wish to have, should be given. Sponging the surface once, twice, or even three or four times a day with water is agreeable to the patient. If fever is very high, when at its hyperpyrexia, use cold water. The higher the fever the more sponging is necessary; it always helps the patient. All the foregoing measures are for the reduction of fever and the elimination and destruction of germs and toxines.

Second Therapeutic Principle.—Do not give food, says the author, at first, unless the patient desires it. As a rule he needs no food until he have eliminated from his blood, tissues, and urine the greater portion of the toxines. It is useless, worse than useless, it is injurious, to give food during the first week of the disease; besides all this, it is unphysiological. The patient is living upon himself. Let him live that way. It is Nature's way, and do not burden him with material which further disorders the digestive, assimilative, and excretory powers. Nothing is gained, but a great deal is lost, and what is the sense in forcing food of a patient who loathes the very sight of it? Nature's water speaks in louder tones than she does in this way, but we do not listen. We are governed by an idea, a theory, and we insist on carrying it out.

Time and again Dr. Roush has seen more diarrhoea and more fever produced by the improper use of food at an improper time, and his rule is very little food during the first eight or ten days, as he knows from observation the patient is better off without it, and will become convalescent sooner.

Third Principle.—No patient in the author's opinion has been treated exactly right who has or continues to have tympanitic bowels. It is the worst symptom, aside from events like hemorrhage or perforation, that the patient can possibly have, even if the tympanites is only moderate, and especially if very great. Nearly every patient that dies has tympanites, has had it nearly all if not all the time. Why, he asks, is it a bad symptom, a dangerous symptom? Because it greatly lowers the powers of life. The pulse gets weak and quick. The patient is restless, can not sleep; delirium and unfavorable symptoms supervene.

What are the causes that bring about this condition? Continued typhoid stools, intoxication from the same, the lessening of the powers of the whole nervous system, but especially of the great sympathetic system. Gas is
generated in the bowels, distention arises for want of muscular power from the innervation, until the muscular coat of the bowels is unable to contract, and peritonitis and death result.

This, says the author, is no fancy sketch; we have all seen it take place dozens of times in all probability. If, unfortunately, we have this condition, what, he asks, is to be done?—Administer small doses of esomel and salol frequently repeated, and large doses of strychnine; also equal parts of turpentine and camphor to the bowels. This will very likely overcome it, if it has not gone to that stage where too great distention has taken place, or peritonitis has supervened.

After the tenth day Dr. Roush usually gives strychnine and continues the same up to and during convalescence, then diluted hydrochloric acid is given in place of saline of ammonium three or four days after fever disappears.

The administration of food begins after the sixth, eighth, or tenth day; the first choice is always milk—sweet milk, or good fresh buttermilk; fruit juices from first to last. The patient will often relish some kind of fruit juice at the first. It is not a food in one sense, but every one knows its beneficial influence in sickness or health. It does not derange the stomach or bowels; it refreshes, makes the stomach better, and helps the patient in ways that we know nothing about, physiologically. It ought to be given as a rule with but few exceptions. Do not use a bedpan. Let the patient get up. The author’s patients get up themselves; they know what they are about; they are not too weak. Do not let that bugbear, perforation, scare you out of your wits. It does not often occur; Dr. Roush practised thirty-two years with two cases only. It helps the patient to get up, gives him an airing, changes his position, and he feels better afterward. Dr. Roush is satisfied that it arouses his vital energies and is a factor in preventing his getting into that dormant state which he saw so frequently in his early practice.

The Primary Channels of Tuberculous Infection in Childhood.—Dr. George F. Still (British Medical Journal, August 19th), in a paper presented to the last meeting of the British Medical Association, arrives at the following conclusions:

1. The commonest channel of infection with tuberculosis in childhood is through the lung. 2. Infection through the intestine is less common in infancy than in later childhood. 3. Milk therefore is not the usual source of tuberculosis in infancy, perhaps owing to the precautions taken in boiling, sterilizing, etc. 4. Inhalation is much the commonest mode of infection in the tuberculosis of childhood, and especially in infancy. 5. The overcrowding of the poorer population in the large towns is probably responsible for much of the tuberculosis of childhood, and prophylaxis must be directed to the prevention of this overcrowding, the improvement of ventilation, and the inoculation of the extreme importance of fresh air during the earliest years of life.

Transfusion in Diabetic Coma.—Dr. Thomas Oliver (Lancet, August 26th) says that there are physicians who do not believe in transfusing with saline solution diabetic patients who are suffering from coma, but he records the ease of a patient who lived two hundred and forty-three days after the operation and who died at a lengthened interval after the transfusion apparently from diabetic coma in the short space of two hours. He does not know what is the longest period a diabetic patient attacked with coma has survived transfusion. It would be interesting, he thinks, to know this, and with the object of eliciting this information he has thought it worth while publishing this case.

A Rare Obstetric Accident.—Dr. H. Mallius (Lancet, August 19th) attended on July 28th a woman, a primipara, with reference to whose case he was rather anxious, as she had early in her pregnancy exhibited a tendency to eclampsia. On arrival at her house he was told that she had already had two slight "stoppages." Finding the os to be fully dilated, he gave chloroform and proceeded to apply forces. The blades slipped over the head with the greatest facility, but when it came to locking the handles, that of the upper blade refused to coapt with its fellow notwithstanding the most careful manipulation. After several failures he decided to withdraw the forces and reapply them. The lower one came away easily, but on attempting to extract the upper one he found it impossible to do so for more than a certain distance. On seeking for the cause of the difficulty the tip of the blade could be felt to be wedged between the head and a much smaller body of an equally firm nature. Any traction on the handle only served to bring this smaller body lower down and increase the impaction of the blade. As the pains were strong and regular and the head was steadily descending, he determined to leave things to Nature and await the solution of the puzzling phenomenon, doing nothing beyond guiding the handle of the imprisoned blade in the right direction. As the delivery of the upper shoulder and arm followed that of the head the tip of the blade came into view, resting in the bend of the elbow, the hand and forearm having through some extraordinary mischance slipped through the fenestra of the blade. As might have been anticipated, the arm was for some days somewhat deficient in power as a result of the accident, but at the time of writing was steadily improving. Never having heard of such a case, Dr. Mallius wrote to Dr. G. E. Herman, the experienced author of Difficult Labor, to ask if he had ever met with a similar one. In a courteous reply he stated that he had never met with, or heard of, such a case.

The Malignity of Paludism in Cuba.—The Sanitarian for August reproduces from the Journal d’hygiene for June 23rd an article on this subject by Dr. Juan Manuel Espada. Dr. Espada says that of all the diseases that prevail in Cuba there is not one that is more destructive of life than paludism or marsh fever. Americans are, very justly, most seriously occupied with yellow fever. But, he asks, can a disease that deals lightly with the natives, that does not attack all foreigners, that often attacks them very lightly, and which produces among those attacked a mortality of twenty or twenty-five per cent, and, finally, which is not subject to relapse, be compared with that other disease that respects no one, that attacks all the inhabitants indiscriminately—to-day or to-morrow or later—if the locality possesses the elements essential to paludic fever, and which may return many times during a lifetime; that invades the whole organism for an indefinitely long period if not for life; which prepares the way for other morbific agents, and which, in fine, constitutes what the ancients called a diathesis, always open for new forms and disposed to aggravate all other intercurrent diseases? Such a comparison is not reasonable unless it is for the purpose of recognizing the far greater malig-
nity of paludism over yellow fever and even over typhoid fever, dysentery, and other diseases that seem more destructive.

A victim of paludism—in other words, of malarial fever—who has the power of resisting disease has been diminished, whose constitution has been undermined after an attack more or less protracted, is seized with grippe, with a pulmonary catarrh, or an enteritis, and dies. The statistician registers the fact, and the report is: Died of grippe, of pulmonary catarrh, of enteritis; but none of these diseases would probably have attacked the patient had it not been for the persistent malaria. The real cause of death is therefore ignored.

An abscess of the liver is formed or a sclerosis of the gland exists during an attack of this paludism, a nephritis with albuminuria, an impoverished condition of the blood, and similar conditions likely to prove fatal in consequence of previous debility and the inroads made on the constitution; but the statistics will not allude in any way to the real cause of death.

Paludism is no longer considered incompatible with tuberculosis. On the contrary, the coexistence of the two diseases is well known. The same is true of other diseases, for tuberculosis seems to be a reservoir toward which other diseases flow as affluents.

But the subject must be considered from another point of view. In all countries that are essentially paludic, all or nearly all the inhabitants are attacked with the disease in a greater or lesser degree. One has the characteristic color of the integuments, in another the digestion is weak; again the liver or the spleen or both at the same time may be enlarged, while others are affected in different ways. Very rarely do we find a person who enjoys perfect health. If occasionally some one is seen who enjoys apparent health there will always be found something latent in the constitution that indicates the working of the disease.

There seems to be a prevailing opinion that paludism as a disease has been nearly eradicated. Not so. It is in such cases the intercurrent diseases that appear on the surface or the more or less remote effects coincident with the disease that mislead the observer. A powerful influence must be assigned to the action of malaria, whether it is manifested as a new attack or exists as a latent element on the appearance of another disease, or, again, is fully developed and reacts on some other disease. In all these complex cases paludism is a dangerous host which sometimes obscures the diagnosis to the prejudice of the patient, influences the prognosis, and limits or completely paralyses all remedial agents.

Curative medicine has only a relative action though a cure is not always impossible. The majority of the sick get comparatively well, but they still live in an infected locality, and it is evident that immunity does not exist in any case, for it is known that one attack always prepares the way for another until the case becomes chronic unless the patient changes his locality.

Too much must not be expected from medicine in cases in which it is manifestly powerless. Hygiene, with the aid of allied sciences, must point out the remedy. Sanitation, proper drainage, pure water, must save the individual. With medicine alone the problem will always remain unsolved, disease will menace health, and, what is worse, will finally triumph.

Permanganate of Potassium in Morphinism.—Dr. Alexander Irvine (Virginia Medical Semi-monthly, August 25th) draws attention to the antitodal power of permanganate of potassium to morphine, and advocates its use in the treatment of the morphine habit to combat in part the violent abstinence symptoms following on withdrawal of the drug.

The Diazoe Reaction in Erysipelas.—M. Coste (Gazette hebdomadaire de médecine et de chirurgie, August 15th), in a Paris thesis, says that the diazoe reaction appears in about two thirds of cases of erysipelas. It is constant in grave ones and those of moderate severity, but is exceptional and nearly always absent in benign cases. Its absence therefore is a hopeful sign in mild cases. In severe ones, however, when it has been present for some days and then disappears without general improvement of symptoms, a fatal issue is to be feared. In consequence of the regularity and intensity with which it appears in cases of erysipelas treated by cold baths it enables us to appreciate how valuable this treatment is for the elimination of toxins. Its prognostic value, says the author, is considerable in the course of severe erysipelas.

Clinical Observations upon Heart Disease.—Janeway (Medical News, August 26th), in a paper read at the Centennial Celebration of the Medical and Chirurgical Faculty of Maryland, said that he was rather incredulous in early medical life when the statement was made to one with heart disease, which from all methods of reasoning was a mitral insufficiency dependent upon organic cause, that he might outgrow it. The late Professor Austin Flint was wont frequently to cheer despondent patients with this hopeful outlook. Dr. Janeway records three cases, all in young girls, of long existing mitral systolic murmur, seemingly organic, which gradually disappeared. Two explanations are offered. The first would assert that during all the years of continuance of the murmur after its first onset in the course of inflammatory rheumatism or other acute febrile disease, there had only been a persistence of such a state as exists in the insufficiency of weakness following disease, and that at no time had there been any distinct thickening or shortening of the mitral valves. The most admitted under this theory would be perhaps some dilatation of the left ventricle, and especially of the mitral ring. It would also be asserted that as the patient became older the muscle force increased, and the base of attachment became firmer, thus diminishing the size of the orifice and finally allowing the valves to so close as to prevent leakage. Under another explanation it might be supposed that the thickening of the valves was not great, the shortening consequently trivial, and that the valve segments may have become united to such an extent as to prevent leakage, but not so considerable degree as to cause the evidence of mitral stenosis. Such an explanation occurred to Dr. Janeway's mind in two cases cited and induced him to endeavor to make out such a mitral presystolic murmur. But listen as he would he could not thoroughly satisfy himself as to its presence. This murmur, it might be stated, did not disappear because of heart weakness, for the patient since the murmur had been lost had been in better health than heretofore, and some of the previous restrictions had been withdrawn.

In two cases cited of Graves's disease, also with mitral insufficiency, the patients were markedly helped toward recovery by the assurance that their heart troubles were not incurable. The treatment consisted of strophanthus and iron, with the addition of digitalis.
when edema of the extremities occurred. Galvanism of the neck was also employed. Complete recovery in one case, and recovery which was complete in all respects but the exophthalmia in the other, ensued.

As regards mitral stenosis, Dr. Janeway said that, contrary to the received opinion which confined the diagnostic auscultatory area to a limited space over and near the apex, in about one third of the cases a probable diagnosis could be made by listening at the back of the chest below the angle of the scapula, where a murmur could be heard, though not so loud or so plain as in front. The author thought that no form of heart disease was more often overlooked than mitral stenosis with only a slight preystolic murmur, and he urged greater attention to it on the part of teachers. In four cases cited by the author the first evidence of cardiac impairment was brought about by exercise at great altitudes.

Dr. Janeway called attention further to the substitution of the 'mitral systolic for the preystolic murmur as the heart’s compensation became markedly disturbed.

The Diagnosis of Malignant Endocarditis.—Dr. Janeway (Medical News, August 26th), in a paper read at the Centennial Celebration of the Medical and Chirurgical Faculty of Maryland, said of the diagnosis of malignant endocarditis that the most frequent inquiry was, so far as the acute malignant type was concerned, whether the patient had possibly any of the malignant types of the ordinary infectious diseases. Especially might the mistake be made between purpura violeosa, cerebro-spinal meningitis, and typhus fever. Only in the large seaboard cities was the last fever likely to be considered. In trying to determine whether a given case was more probably due to endocarditis or to another malignant process he had found that attention to the position of the hemorrhages was at times very helpful. Several times he had noted numerous small hemorrhages with slight nodular character in the palms of the hands and in the soles of the feet, when possibly the arms and the legs had but a scanty crop in malignant endocarditis, whereas this had not been his experience with the processes likely to be mistaken for it. The presence of hemorrhages in the conjunctiva was also more in favor of this disease, particularly if the inquiry was between it and typhus fever. While the presence of a heart murmur, together with the above events, suggested strongly ulcerative or malignant endocarditis, it was well not to argue thus without a definite basis. There existed no reason why a person with heart disease should not develop one of the malignant types of fevers. If a patient were in a hospital ward, a hotel, or a boarding house, then we were compelled to endeavor to solve the question at as early a period as possible with a view to the patient’s isolation or removal if he should perhaps have another process than endocarditis. Hence we were obliged not alone to consider the probable diagnosis as made from the events, but also to institute an inquiry as to previous vaccination, and possible exposure to some disease within a recent period. There were certain phenomena in a doubtful case which had great weight, as the occurrence of embolic processes, as proved by the development of hemiplegia, aphasia, or by the proof of the blocking of an artery of the limbs. These phenomena would not occur in the other types of disease. A heart murmur, if none were known to have previously existed, or if the one previously present had altered in character, taken in conjunction with these phenomena made the diagnosis of malignant endocarditis as near a certainty as anything in medicine.

Proceedings of Societies.

SOCIETY OF THE ALUMNI OF THE CITY (CHARITY) HOSPITAL.

Meeting of May 10, 1899.

The President, Dr. William L. Stowell, in the Chair.

Calculus Pyonephrosis.—Dr. Alvah M. Newman stated that through the kindness of Dr. Charles McBurney he showed a specimen of calculus pyonephrosis with multiple abscesses. The patient was about forty-nine years old, and for the past two years found some difficulty in lying on the left side; there was some tenderness, and occasionally the skirt bands troubled her. With these exceptions she enjoyed fairly good health. On the 4th of February, about midnight, she was taken with a severe attack of renal colic. These attacks continued for fourteen days with varying intensity and duration, and at the end of that time she passed a cast about an inch and a half long and a quarter of an inch in diameter, which looked like a fibrinated blood clot. Dr. James Ewing examined it and found it composed of pus and mucus. Immediately after passing the cast the patient’s general condition improved. Previous to passing the cast the patient voided about eighteen ounces of urine, with but few pus cells, during the twenty-four hours. This evidently was secreted by the right kidney. Ten days later the patient passed four or five ounces of pus; this cleared the diagnosis, and the speaker advised operation. Dr. Tilden Brown catheterized the ureters; from the right urine flowed freely, from the left seven drops in eighteen minutes; the catheter was full of pus when withdrawn. Dr. McBurney removed the kidney on April 27th. A large calculus was found in the pelvis. For the ten days following the operation the patient averaged sixteen to seventeen ounces of urine; for the four days (end of two weeks), about thirty ounces. Temperature remained below 101° F.; pulse, 118 to 123; respiration, 24 to 36. Patient is now free from pain and doing well. Up to the time of passing pus there were no constitutional symptoms.

The President said this case was interesting in two or three ways, the most important point being that the patient was making an excellent recovery after the removal of such an exceedingly pathological kidney.

Dr. Adolph Ruppe asked concerning the constitutional symptoms leading to the special diagnosis. Had there been any pain in the lumbar region simulating lumbar neuralgia or sciatica? The special symptoms in the beginning seemed to have been rather obscure.

Dr. W. L. Baner spoke of a case he had seen of pyonephrosis. The patient a year ago last winter was suddenly seized with a very sharp pain in the abdomen. When the speaker saw her she had a temperature of 103° F., a great deal of tenderness at McBurney’s point, and rigidity of the abdominal muscles. He diagnosed it as appendicitis, and the attending physician agreed with him. A surgeon who was called in decided that he would postpone operation, but said
there was no doubt it was appendicitis. The following day the patient was much better and the temperature had gone down nearly to normal. On the third day the urine became very offensive and the examination showed that it was full of pus. That went on for some days and got worse; there was a tremendous flow of pus with all the evidence of coming from the kidney; then the patient began to get better and the pus disappeared almost entirely from the urine. The patient's general health improved, but she still considered herself an invalid. This winter she had had a bad cold, and following it the same history repeated itself, with the exception that the onset was less acute and there were a number of small calculi of uric acid passed. The speaker had a number of times advised operation to have the suppurring sac removed, but it had not been permitted as yet. He had no doubt there were calculi of considerable size there, and doubted if complete recovery was possible without operative interference.

Hysterical Blindness.—Dr. A. T. Muzzy read a paper on this subject. (See page 403.)

Dr. William M. Leszynsky said he had seen many cases. Before accepting the statement of the patient that she was blind in one eye, and before making an ophthalmoscopic examination and testing the vision, much could be learned by an examination of the pupils. He did not think ophthalmologists laid sufficient stress on such examination. If a patient complained of being blind in one eye, and he found upon investigation that the pupils were normal in appearance and in their reaction to light, he was led to conclude that the patient was not blind in one eye. But, if the pupil of the alleged blind eye did not react directly to light, but reacted vigorously when the other eye was suddenly illuminated, he at once assumed that the patient was telling the truth, and that there was some trouble in the eye. He spoke of a patient who had been under his care for some time with facial paralysis. One day she complained that she was totally blind in one eye. On examination he found that the pupillary reaction was very strong on indirect illumination, but it did not react directly to light, and further examination revealed edema of the retina, which soon after manifested itself as a unilateral retrobulbar neuritis. Many of these patients had their vision improved by glasses, simply window glass, and that was accomplished through suggestion. Patients suffering from hysterical blindness thought they could not see, but they did see, however. It was merely a peculiar condition of consciousness which obliterated their vision. He had never seen a case of hysterical amblyopia with a central scotoma. The central scotoma referred to in the paper, an absolute scotoma, namely, for colors and for light, was more likely to occur in patients with organic disease—in retrobulbar neuritis. It was not unusual for such a condition to arise in the course of disseminated sclerosis. The history of a fall might have some bearing upon the case. The woman's age was not against it, although the disease occurred more frequently in younger people. The fact that she had a diminution of vision that had been progressive in both eyes, and a central scotoma, would lead one to suspect organic disease. When one finds a visual disturbance thought to be functional, every neurologist would consider the associated symptoms; that is, he would observe the patient from the standpoint of her general condition and as to other manifestations of hysteria. Very often there was a loss of sensibility on one side, not only anesthesia of the cornea and conjunctiva with diminished vision, but loss of the senses of smell and hearing. It was hardly wise, in every case of eye trouble where there were associated symptoms, to consider them hysterical, because an hysterical patient was not exempt from any form of organic disease. These cases must be studied from the standpoint of neurology as well as from that of ophthalmology. The urine should always be examined. Diabetic patients were known to present similar eye symptoms. Probably Dr. Rupp, whose patient this was, could throw some light on her general condition. He himself had seen quite a number of patients with the various forms of amblyopia—blindness of one eye, blindness temporarily affecting both eyes, hysterical blepharospasm—and all of these patients recovered. They either recovered through attention to their general health and through suggestion in various forms, or they recovered spontaneously. It was mere guesswork to express an opinion as to the duration of such symptoms. A patient with hysterical aphonia, after application of the will, made the larynx, recovered six or seven consecutive times through suggestion. Afterward her aphonia returned, and she had been aphonic for a very long time (a period of over a year). He also referred to the case of a boy, about ten years old, whose father brought him and said the boy was blind in one eye. He was examined carefully, and absolutely nothing could be found to indicate blindness. He was examined repeatedly. It was at once found that he was not blind. When a strong convex glass was placed over the healthy eye he read all the letters on the card down to §3, showing that he had normal vision in the supposedly blind eye. This was not an unusual experience in such cases. Soon after recovery occurred spontaneously.

Dr. A. Rupp said that hysterical blindness was from the point of view of the general practitioner but an interesting part of a large general subject, which was gratefully surrendered to the eye or nerve specialist, who could do as little for this evil as himself. The case of a man was referred to which had been diagnosed by high eye authority as probably hysterical, but the man died several years later of pronounced brain disease. Concerning the present case reported by Dr. Muzzy, the urinary examinations had turned out negative. When not conscious of her blindness the woman walked well enough, but when in the house, surrounded by pitying friends, she walked in a clumsy way. The woman was nervous and neurasthenic. Besides the points already emphasized by Dr. Muzzy and Dr. Leszynsky, it should not be overlooked that the trouble might last for years.

Dr. H. S. Oppenheimer said that these cases occurred quite frequently. The previous speaker had related the case of a boy, ten years old, which reminded him of a case of his in a boy of about that age. The story was that in coming home from school a little boy had thrown a handful of sand in his right eye and he had been unable to see since. He was very much alarmed about it. On exposing the eye that he apparently was blind in he could not see the speckled fingers: all this with a perfectly calm, assured face. In testing him with prisms he could see two lines easily; then, by covering the good eye with a strong convex glass, through which he could not possibly see at a distance of twenty feet, the boy read very well at that distance. The speaker sent him into the parlor and told his father that he was not blind, but that he probably thought he was, explaining the test by which he came
to the conclusion that the boy could see very well. The father was incredulous, but on putting on the glass himself found he could not see across the room. He tried the boy again and found, of course, that he read well with the eye that he supposed was blind. The father wanted to know what he should do, and the speaker advised some tonics and an eye water, largely as a matter of suggestion. About a week after the father came back with the boy and said that he was surely blind, and the speaker had to go through the same argument with the father again to show him that the boy was not blind in that eye, and he went away satisfied. He came back a third time to have this argument renewed, and said he would bring the boy about once a month. He never brought him again. He probably came to his vision before there was any occasion to bring him.

A case which the speaker had treated about ten years ago was that of a young lady, at that time eighteen or twenty. She was a music teacher. Her father had been insane for years; the mother was a very nervous woman, now dead. This young girl, who was a sensible, bright young woman, came in a most terrible condition of mind. She had gone to two or three different oculists who had simply laughed her out of court, as it were, and not given her any satisfaction whatever. She finally came to the speaker, who found that the eye which she thought was blind, so far as the ophthalmoscopic appearance was concerned, was absolutely normal. She could not see a thing, so far as she knew, when she knew she was looking with that eye. He told her that she would get well, but was rather short about it, and she went home a little crestfallen. She came back the morning in the greatest state of excitement and said she had looked up the matter and did not think that she could see double with prisms, as she had done, unless she could see with the eye she was blind in; that it had kept her awake all night and got her into a state of tremendous distress. He told her she was not going crazy, she could see two lights as she was improving, and with tonics and other treatment she would get well. He reassured her, for if she had thought she could see all the time when she was satisfied she could not, she would take it as the first symptom of insanity and destroy herself. He told her that the color field would come back rather rapidly after taking the strychnine. It was suggestion more than anything else. In two or three months she was conscious that her eye was all right. He wished to emphasize that the great difficulty in diagnosing these cases was not so much as to whether the trouble was organic or functional, but to judge between malingerers and people who were hysterical or had functional trouble. He spoke of a patient who had been in the Prussian army who insisted he could not see. The eyes apparently were absolutely normal. The man had been helped because people were sorry for him. His wife used to bring him around, and the speaker was satisfied that the man was not blind. He tried nitrite of amyl, everything that could be suggested, and the man persisted that he could not see, and eventually passed out of his observation without the least acknowledgment that he had received any benefit. He was still in doubt as to whether it was simulation, or there was something in that man's brain which prevented his seeing with a healthy nerve and retina. The condition called hysterical amblyopia showed itself just as much in the male as in the female. There might be paresis of the eye muscles in hysteria, which had been doubted and disputed by a great many good authorities. Many of them insisted that in the vast majority of cases it was nothing but the spasm of the opposing muscle. 

(To be concluded.)

**Book Notices.**

We can hardly say too much in praise of the first volume of this work. In it the writers have adopted an easy yet forcible style which holds our attention throughout, for there are no long drawn-out historical sketches, but each subject is dealt with sharply, shortly, and to the point. The authors assume that their readers are already familiar with surgical diseases, and only refer to the diagnosis, pathology, and symptoms to elucidate the treatment. The book is therefore of value to students only in conjunction with other works on general surgery. It is noteworthy, too, that exceptional cases have been omitted and only such are described as are commonly met with.

The first volume is divided into sixteen chapters, and contains two hundred and seventy illustrations. It is small and compact and easily held in the hand for comfortable reading. The type is perhaps rather too small, but we can overlook this defect in view of the clear and concise division of each chapter. We have but little to dissent from in the volume. A few matters call for our consideration, however, and among them that of leeches, which the authors advise in the chapter on acute inflammation. These we would replace by more aseptic methods, such as position, bloodletting, cold, heat, and antiseptic fomentations. It is but fair to state, however, that all these receive mention.

Chapter ii, on acute suppuration, which includes circumscribed acute abscesses and diffuse inflammation of cellular tissue, is handled in a masterly manner. The elaborate arrangement of the mackintosh (there are two illustrations of this) could perhaps be done away with by the substitution of a Kelly pad, which would simplify the nursing. The devices spoken of later in the chapter are all interesting and valuable.

As concerns chapter iii, we have but one suggestion to make, for we think ether better than turpentine in the disinfection of ulcers, the sebaceous secretions being more soluble in the former, but, on the other hand, no doubt most ulcers would heal rapidly under the treatment advised.

Dr. Frederick W. Silk contributes the fifth chapter, on anaesthetics, and we note that he has omitted to mention the hypotonic injection of cocaine into the spinal canal for operations below the site of injection. This is, however, of small moment. Dr. Silk speaks disparagingly of the use of morphine in conjunction
with a general anesthetic. "The routine use of mor-
phine, even in combination with atropine, is deprecated by
most anesthetists; its advantages are more theore-
tical than practical, and its tendency to mask the symp-
toms of overnarcosis has more than once led to fatal re-
results." There is no denying that the use of morphine
with an anesthetic is only permissible in a few oper-
ations about the mouth, where the surgeon gives the an-
esthetist but few chances to keep his patient quiet.
We note a partiality for the A. C. E. mixture, which is
perhaps not so popular with us as ether or chloroform
alone. We are advised to use the A. C. E. mixture,
especially in renal disease. For our part, we like ni-
trous oxide and oxygen, and to these the writer has
given but little space, in spite of their growing popu-
ularity.
Under the head of special cases, a preliminary
injection of morphine is recommended, but this is hardly
in accord with the remarks in the earlier part of the
chapter. Nélaton's method of inverting the patient as
a means of resuscitation we consider of questionable
value. The chapter concludes with a description of
Schleich's infiltration method, but does not indorse it
except for minor operations.

Chapters vi to x describe the varieties of wounds
with their complications and treatment, all of which
are dealt with cleverly. We would hardly give tra-
matic fever a separate description, but rather include
it under the head of septicemia or pyemia. The au-
thor states that "when it occurs, the reactionary pyrexia
which often follows operations performed antiseptically
runs up to 103° or 104° F. instead of abating, and then
slowly begins to fall in an intermittent descent coincid-
ing with the complete establishment of granulation.
This condition of traumatic fever, unless it occurs in se-
pticemia or pyemia, does not usually prove fatal; at the
same time suppuration always occurs in the wound." 
Under such circumstances we should fear that the asеп-
sis has been faulty, and call the condition simply a seп-
tic one.

The four remaining chapters concern affections of
eciatrics, syphilis, chancroid, or soft sore, tuberculosis,
and tumors.

We rate the volume most highly, and we look for-
ward with pleasure to the coming ones.

_Cyclopedia of the Diseases of Children; Medical and
Surgical._ The Articles Written Especially for the
Work by American, British, and Canadian Authors.
Volume V. Supplement. Edited by William A.
Edwards, M. D. Illustrated. Philadelphia: J. B.

This work aims to be, the editor states, a continua-
tion of the _Cyclopedia_ the last volume of which ap-
peared ten years ago. It is in the same style, and in its
make-up resembles the original work. It is well printed
and contains a goodly number of excellent illustrations.

The volume is the product of eighty-seven different
contributors, eighty of whom have written but one arti-
cle each, and no one more than three articles. These
cover the important topics in pediatrics, and besides
contain many articles of general scope and interest.
Some of these are of great excellence; very many do
not rise above mediocrity and add nothing to existing
knowledge.

The work does not really give us the advances in
pediatrics in ten years. Had this been its scope, rigid-
ly adhered to, a volume of the greatest value might have
been produced. Several of the articles are of this char-
acter, and the success of them shows what might have
been done in all.

Some articles have been reprinted from the origi-
nal work with few or no changes; some have been
the subject of revision by the original contributors; very
many are articles by new authors upon subjects treated
in the original work and in much the same way.
The result of the whole is a somewhat peculiar
product. We have not here a text-book or a real supple-
ment, but a sort of one-volume cyclopædia.

While it is a work which the specialist will hardly
be willing to do without, yet it is to be doubted very
much whether the general practitioner will find in it
much which he does not now possess in his text-books in
a more compact and agreeable form.

_Traité de l'allaitement et de l'alimentation des enfants
du premier âge._ Par le Dr. A.-B. Marfan, Pro-
fesseur agrégé à l'Université de Paris, etc. Avec 22
Pp. xiii-443. [Prix, 10 fr.]

This is an admirable volume, bringing together a
large mass of interesting and valuable material much
of which has existed hitherto only in periodical litera-
ture.

It gives us the present status of infant feeding in
France, and presents quite fully the opinions of Ger-
man writers on the subject, and very briefly those of
American and English writers.

The book opens with a chapter of 94 pages devoted
to breast milk, its composition, tests of it, the condi-
tions modifying the secretion, etc. Then follow chap-
ters upon lactation, milk digestion, and the growth of
infants.

The third part of the book is devoted to artificial
feeding. In connection with this are discussed the ster-
ilization and modification of cow's milk. Sterilization
at high temperatures (230° F.) is advocated in all cases
where the milk is not fresh when received.

The early age at which pure cow's milk is given to
infants will strike the American reader as surprising.
As a rule this is recommended for infants over four or
five months old, and in many cases is advised at a much
erlier age, especially for some wasted cachectic in-
fants, with whom it is to be used in very small quan-
tities.

In reading the chapters upon milk modification one
is anew impressed with the immense advantage of the
American method of stating the proportions of the milk
ingredients in percentages, instead of using such terms
as natural milk, natural cream, etc., or "the mixture"
of this or that writer.

While we can by no means agree to all the conclu-
sions of the author, the book is a suggestive one, and
well worth careful reading by every one interested in
the subject of infant feeding.

_Clinical Lectures on Neurasthenia._ By Thomas D.
Savill, M. D., Physician to the West-End Hospital
for Diseases of the Nervous System, London, etc.
[Price, 3s. 6d.]

This little volume consists of lectures delivered by
the author in the Welbeck Street Hospital for Diseases
of the Nervous System. The subject is of importance,
and is too often neglected and slighted. While the au-
In this department the writer's extensive acquaintance with his subject shows to excellent advantage. The page of description of streptothoraces is a model of compactness.

Dr. Novy's work, therefore, gives a distinct personal impression of an expert bacteriologist and experienced teacher. It reminds one less of the burden of compilation than most other volumes of this class, and is well calculated to excite the lively interest in the subject which the author aims to induce in his students.

Miscellany.

The Medical Service of the British Army and that of India.—The home service seems to be less attractive to our young British brethren than the Indian service. The British Medical Journal for August 19th says: "The result of the recent examination for commissions in the medical services announced in our columns last week can not be considered altogether satisfactory. In fact, it is anything but reassuring as regards the Royal Army Medical Corps; both the number of qualified candidates and the marks gained in that corps are disap-
MISCELLANY.

Overtraining.—Dr. Eugene A. Darling (Boston Medical and Surgical Journal, August 31st and September 7th) thus concludes an article on The Effects of Training, a Study of the Harvard Crews:

"The real condition at the bottom of overtraining is still obscure, but in the light of this inquiry certain possibilities are suggested as factors which may have to do with its causation.

"The first and most obvious one is the condition of the heart. We have seen that a great increase in size and strength is demanded of this organ and it may easily happen that it is called upon for more work than it is able to do, and that instead of establishing a compensatory hypertrophy it becomes dilated and weakened. A 'broken-winded' athlete is probably one with a dilated, flabby heart.

"The second possible factor is the condition of nutrition. This is more difficult of demonstration than the first. As already pointed out, the nutrition may be disturbed in two ways, either by an improper diet, in which the nutritive elements are not apportioned to the needs of the body, or by disturbed digestion, as a result of which the food taken into the body is not utilized. That both of these contingencies may occur has been sufficiently demonstrated.

"The third factor may be simple overwork. This is not so likely as the two preceding, for, when properly nourished, the capacity for work on the part of healthy young men is certainly much greater than that demanded in training. The peculiarity of training work, however, is its concentration. It may be that the excessive work accomplished in a brief space of time exhausts the muscles so that they do not recuperate before being called upon for a repetition of the work—that there is, so to speak, an accumulation of fatigue, and that this constitutes overtraining.

"The fourth factor which suggests itself is a nervous one, and this, while more intangible than the others, is unquestionably an important one. In the present state of our knowledge it can only be surmised, not proved. It is well known that there is a nervous fatigue entirely distinct from muscular fatigue and resulting from prolonged anxiety, from monotony of work, and from numerous other causes. It may be that anxiety about a coming contest, together with the prolonged mental strain of mastering the technicalities of such a difficult art as rowing or such a complicated game as football, may lead to a condition of nervous exhaustion, and that this nervous exhaustion contributes to overtraining.

"No one of these factors will account for all cases of overtraining and probably more than one cause must be admitted. At any rate, it is safe to suggest certain points which should be borne in mind in laying out any course of training. They are: 1, not to throw too much work upon the muscles, and especially upon the heart, until they are strengthened by preliminary work; 2, to watch the nutrition carefully, and 3, to avoid nervous fatigue by providing a certain variety of exercise, and by not confining the attention too closely to the approaching contest.

"Finally, this investigation has demonstrated that the physiological effects of training, on the heart and kidneys in particular, may approach unpleasantly near to pathological conditions, and that there should be some competent supervision to insure that the safe limits, when those are determined, shall not be passed."

Tobacco Smoke and Hypertrophic Rhinitis.—Dr. W. E. Dicken, of Kahoka, Missouri, writes to us suggesting that patients who are addicted to the use of tobacco and have hypertrophic rhinitis will find great relief by spraying the nose with a two-per-cent. solution of cocaine or inhaling tobacco smoke through the nose until the mucous membrane is thoroughly parched or seared by the smoke—the stronger the tobacco used the better. This is also, he says, very beneficial in hay fever. Tobacco smoke, being a strong antiseptic, will kill the microbes which are supposed by some to be the cause of the disease, and will reduce the irritability of the nasal mucous membrane.

An Army Medical Examination at Manila.—According to the Boston Medical and Surgical Journal for September 7th, recent orders constitute the medical officers on board the hospital ship Missouri into an examining board, for the purpose of passing upon the merits of candidates for commissions in the medical corps now serving in the Philippines. At the last examination, held during the past winter, the medical men
serving in the Orient were debarred by distance from appearing as candidates. There are now several existing and expected vacancies in the corps, and these Surgeon-General Sternberg has justly decided should be filled from the score or more applicants who have rendered such valuable service at the front. The examining board is directed to convene as soon as Manila is reached.

Women at the University of Strassburg.—The Lancet for August 26th announces that the University of Strassburg, which, like the other German universities, has hitherto declined to admit women as students, has now authorized the attendance of those whose general education is found satisfactory.

A False Report of Plague in London.—According to the Lancet for August 26th, the report that a case of bubonic plague had been received at the Middlesex hospital is entirely unfounded. The Lancet on investigation found that not only had no such case occurred at the hospital, but no case in any way resembling plague had been under treatment. "It is to be regretted," says the Lancet, "that the lay papers do not seek corroboration of such statements before making them public, as needless alarm is thereby occasioned."

We heartily endorse this sentiment as of even greater importance on this side of the Atlantic.

The Military Medical Arrangements for the Philippines.—According to the Army and Navy Journal for September 2d, Surgeon-General Sternberg has directed Chief Surgeon Woodhull at Manila to begin immediate preparations for the enlargement of the medical department and hospital accommodations at Manila to conform to the increased army of sixty-three thousand men. As the time required for the construction of a large wooden hospital would be at least six months, it will be necessary to depend upon buildings already constructed, which may be obtained for the purpose, or upon tents. The quartermaster-general has been ordered to send to the Philippines five hundred hospital tents for use. It is suggested to Colonel Woodhull that as time will be required for the establishment of a tent hospital he should select locations and establish the hospitals without delay. He is also asked to report by cable on the number of female nurses he will require. The medical departments will send two hundred and fifty members of the hospital corps on the Missouri and twenty female nurses on the Relief. The nurses were asked for by Colonel Woodhull, who is told that medical officers are being sent as rapidly as possible. Four experienced surgeons of volunteers with the rank of major are now under orders for Manila, in addition to the commissioned medical officers belonging to the new volunteer regiments.

Christian Science as a Producer of Disease.—The following excellent and pertinent remarks appear in the New York Times for September 8th: "Much of the leniency with which 'Christian Science' and the many kindred frauds are regarded is due, presumably, to a general impression that when the 'healers' heal, as they occasionally do, a desirable object is attained, and that the victims of their incantations are the willing dupes of their own folly, and therefore not deserving of any very active sympathy. This view of the matter is not altogether without excuse, but it is a narrow, and consequently deceptive, view. Nobody, so far as we have noted, has yet emphasized, or even mentioned, the fact that the power, the very real power, wielded by the faith cure fraternity, a few of whom are well-intentioned fanatics and the rest unscrupulous money hunters, can be as easily used for the destruction of health as for its improvement. The key word to all of these mysteries is 'suggestion,' and he or she who drives away certain illnesses by starting the subliminal consciousness at work upon them is able by the same means to produce those same illnesses in a person entirely well. That precisely this thing has been done voluntarily was shown in the article by Dr. Seelye, upon which we commented recently. That it is done voluntarily and systematically we do not know, but in estimating the probability of such crimes one must take into account, first, their possibility; second, that they would be almost beyond detection and punishment; third, that they could obviously be made an effective implement of extortion; and, lastly, the mental and moral characteristics of the men and women who are living comfortably or getting up big fortunes by the adroit manipulation of human credulity. Having given due weight to all these points, who will be bold enough to assert that faith killing is not going on as well as faith curing, that maladies are not created by faith as well as destroyed by it?"

The Portuguese Faculty of Medicine and Quarantine.—According to a telegram to the New York Times for September 8th from Oporto, the faculty of medicine has telegraphed to King Charles asking him to go there in person and "see the uselessness of the vigorous quarantine."

The physicians belittle the seriousness of the plague outbreak.

The Eleventh Annual Meeting of the Tri-State Medical Society of Alabama, Georgia, and Tennessee is announced to be held in Chattanooga on Tuesday, Wednesday, and Thursday, October 24, 25, and 26, 1899. Those desiring to read papers are requested to send titles to the secretary, Frank Trester Smith, Chattanooga. There is every reason to hope for a large and successful meeting.

The Mississippi Valley Medical Association.—The twenty-fifth annual meeting will be held in Chicago on Tuesday, Wednesday, Thursday, and Friday, October 3d, 4th, 5th, and 6th, under the presidency of Dr. Duncan Eve, of Nashville. The address in medicine will be given by Dr. J. A. Witherspoon, of Nashville, and the address in surgery by Dr. Lewis S. McMurtry, of Louisville. The programme gives the titles of sixty papers in addition.

The University of Pennsylvania and the Pennsylvania State Medical Examination.—We are informed that of one hundred and forty-three students from the University of Pennsylvania examined by the State board of medical examiners of Pennsylvania only one failed, and that the general average of the whole number was eighty-six, an average decidedly in advance of that obtained from any other school. The Women's College comes next with twenty-eight candidates and no failures, the general average attained by the students being 81.22. The average all through appears to be high, the lowest being 72.84, and since the University of Pennsylvania furnished about thirty-four per cent. of the entire number of candidates, this makes the university's record all the more noticeable.
Original Communications.

FRACTURE OF THE LOWER END OF THE RADIUS.
By CARL BECK, M. D., NEW YORK.

(Concluded from page 305.)

Treatment.—The first requirement, accurate reduction, may be carried out with little difficulty by moderate extension, the flexed hand being grasped as in a firm handshake, with downward pressure by the surgeon's thumb, while counter-extension is used on the forearm, which is flexed rectangularly. If this procedure should fail, anaesthesia must be employed.

Fig. 6 shows the extra-articular type in a youth of twenty years (patient presented to the association April 17th) twelve days after the injury. A dorsal and a palmar splint were applied, but no effort had been made to reduce the displacement, which explained the swelling. The latter at last reached such an extent that gangrene of the dorsum of the hand developed under the dorsal splint.

While it is emphasized that thorough reposition is the conditio sine qua non, it should never be attempted by other than gentle manipulations. In recent cases this will easily be accomplished. In old cases considerable difficulties will arise. In Case VI complete reduction was effected, as shown by Fig. 7, although the displacement had lasted fully twelve days. But a moderate degree of force was used; still it seems to me that while using lateral pressure for the reduction, a small particle of the styloid process of the ulna was severed. In Fig. 6, which was taken before reposition, the styloid process appears intact. As will be shown below, this complication is one of great importance. The patient is not now incommmoded by this complication, three months after the injury.

The more difficult thing is to keep the fragments well adjusted in a proper position. This I have always been able to secure by very simple methods. While forced traction is made, a long adaptable wire splint is applied, which reaches at the flexor side of the arm from the tips of the fingers to the elbow. If the direction of the displacement is upward (silver-fork shape), a pad of adhesive plaster is attached to the dorsal integument above the fragment. Then a short, narrow splint of wood is placed on the dorsal aspect of the arm, reaching from the metacarpo-phalangeal joint to four inches above the wrist, and is kept pressing down by the application of a gauze bandage.

If the tendency of the displacement is downward, the same procedure is carried out in the opposite direction, the wire splint being applied on the dorsal and the wooden splint and pad on the palmar side of the arm.

If the displacement is sideways, which is most marked when there is a simultaneous injury of the ulna (Fig. 2, left hand), the immobilization must be carried out on entirely different lines. The adhesive-plaster pad must then be applied laterally to the fragment, two long, narrow wooden splints being used at the same time. One of these splints, being a little broader than the diameter of the bone, begins at the metacarpo-phalangeal joint of the thumb, and the other at the same point of the little finger. Both extend up to the elbow, the same as the long wire splint. If there should be any displacement in the opposite direction, the pad must be applied on the ulnar side. No dorsal splint is used in this variety. After the dressing is finished the skgagram verifies the proper position of the fragments.

If there is much swelling, wet applications may be advantageously used by pouring Burow's solution upon the gauze bandage, the wire splint permitting penetration of the fluid.

If after the lapse of a week agglutination of the fragments is obtained, and no deformity is evident, then the soft tissues must receive consideration. It is only then that short splints are in order. They consist of well-padded pieces of wood extending from the metacarpo-phalangeal joint up to the middle of the fore-
arm. After another week a bracelet, such as is recommended for the treatment of simple fissure (see above), is applied to permit of free action of the fingers. The patient is also told to move his fingers as in playing the piano, and to use the marbles as described in the treatment of fissure.

After the third week massage treatment is indicated, active as well as passive motion of the joint being employed at the same time. The results of these simple methods are just as good as, if not better than, those of the numerous most complicated apparatus advised for the same purpose. If all the points of these manipulations, dictated by simple common sense, are observed, surgical clinics will no longer furnish so much testimony of deformities and functional impairment following fracture of the lower end of the radius.

In cases of severe functional disturbance of the joint, produced by agglutination of the fragments in a displaced position, I have succeeded repeatedly in reducing the deformity by osteotomy. In every case the functional result has been very satisfactory. Osteotomy is also indicated in cases of extreme callus formation, such as is illustrated by Fig. 8.

Operative interference may also be required if pronation and supination are arrested on account of callus formation between radius and ulna, as is illustrated by Fig. 9, which was taken ten weeks after simultaneous fracture of radius and ulna had occurred.

In Fig. 10 the excessive callus formation due to a non-displaced fracture in a boy of fifteen years was not followed by any functional disturbance, wherefore removal of the excessive bone tissue was not advised. In this case it had been pronounced that vicious union was present. But the patient could be convinced by his sketch that he had been treated correctly. The medicolegal importance of the possession of such a “document” is evident.

Fractures of the lower end of the radius, combined with fissure or fracture of the head of the ulna, are frequent (Fig. 11). In my cases this combination represents twenty-three per cent. of all cases of fracture of the lower end of the radius.

In case of fissure of the ulna no displacement is present, and the symptoms are essentially the same as those of the complete fractures described above.
In the much rarer event of complete fracture of the ulna the symptoms of lateral displacement are well pronounced. This combination is the main cause of the impairment of supination and pronation.

The treatment is practically the same as that of complete fracture with lateral displacement, lateral pressure, by attaching an adhesive-plaster pad over the ulnar fragment after reduction, being well kept up. In case of displacement a plaster-of-Paris dressing is preferable for the first ten days.

Fracture of the lower end of the radius, combined with fracture of the styloid process of the ulna, is extremely frequent (Fig. 12). In the writer's cases this combination represents forty-two per cent. of all cases of fracture of the lower end of the radius. In this variety the radio-ulnar joint is always more or less involved (compare Fig. 2).

It is evident that it is more difficult to keep the fragments in good apposition in this type. It is therefore advisable to apply a plaster-of-Paris dressing while traction is used, the hand being firmly grasped by an assistant and kept in slight ulnar flexion. The Röntgen rays permeating the plaster dressing, the proper position of the fragments can be verified by them. If apposition appears to be imperfect, there is a chance for immediate correction and certification of its proper execution. It is true that the x-ray taken through the plaster dressing is not so distinct, but, as Fig. 13 shows, still distinct enough to indicate the position of the fragments. In obstinate cases resection of the process is sometimes indicated.

In the majority of cases observed by me the process has been entirely severed. It seems that osseous union never takes place again. (Compare Fig. 14, an illustration of the case of a lady, seventy-one years old, who had sustained a fracture of the lower end of the left radius three years before and one of the right radius two years before. The process appears to be entirely isolated on the left side. Still, there is but insignificant deformity.)

Appendix.—The functional impairment following fracture of the lower end of the radius, especially the formation of adhesions, has led a number of surgeons to enunciate this dogma: “The most important part in the treatment of fracture of the lower end of the radius is the treatment of the soft tissues.” Nothing is more adverse to common sense than this dangerous axiom, which is based upon correct observation, but incorrect interpretation.

Galen says that the bones give the human body form, erectness, and firmness. It is evident that an injury of the bones impairs these three fundamental factors.
The most important step toward repair must thus be taken in the foundations rather than in the superimposed structure. And in no part of the body is this principle more conspicuously illustrated than in the wrist, which is so preeminently governed by the lower end of the radius. The wrist directs the hand, this wonderful and important mechanism, without which the whole extremity would be a nearly useless appendage. In fact, the hand is, more than any other portion of the body, the instrument with which mankind has reached its superiority; and from it the most wonderful and delicate art, surgery, derives its name.

If the lower end of the radius is displaced, undue pressure must necessarily be made upon the soft tissues; non-reduction means persistence of pressure, the fatal consequences of which are only too well known. Reduction means the relief of pressure. Of course the act of injury can not be undone by the mere cessation of pressure. But the influence of the injury on the soft tissues, if the pressure lasts only a short time, is insignificant; there is then but little inflammation and consequently little exudation, and therefore repair is easy. This means that the premises of adhesion formation are wanting. And clinical observation shows that, if there was perfect reposition, the wrist as well as the sheaths will be found free, even if the wrist has been immobilized longer than necessary.

Thus it can be seen that, as in the treatment of all fractures, there are two simple rules—viz.: first reduce the displaced fragment, and then keep it there.

The *sine qua non* for the proper execution of these three points is an *exact diagnosis*. In many cases, it is true, the presence of a fracture may be recognized even by simple inspection. And if a false point of motion, crepitus, and displacement are present, the proof of the presence of a fracture is established beyond doubt. But with all their experience and knowledge, the greatest surgical masters of all centuries have often failed to diagnosticate fractures. The courts can tell endless histories of grave errors to the detriment of poor patients and none the less of poor doctors.

Like witchcraft appeared the discovery of Wilhelm Conrad Röntgen, which did away with these repeated miseries. Now there are no more fractures the presence of which can not be established beyond doubt. But much more has been given to us by the miraculous rays: A glance with the fluoroscope furnishes not only a true picture of the special type of the fracture, but one of the situation, the shape, and the number of fragments (compare Fig. 11), and their correlation can be distinctly ascertained, so that anaesthesia, which in many such cases is not at all indifferent for the pa-
pient’s physical condition, is no longer required for diagnostic purposes. It is self-evident that thus the advent of the Röntgen rays means no less than a revolution in the understanding of fractures.

It is to be deplored that several circumstances are adverse to their general adoption by the profession. The great financial sacrifice and the trouble which taxes the surgeon’s patience, often to a great extent, are inimical to their popularity. A great deal is also heard lately of the various dangers of the Röntgen rays.

A few weeks ago the dangers of the Röntgen rays were commented on in a most interesting editorial in this journal. But I venture to say that the danger of using the rays nowadays is much less than the danger of not using them. That the Röntgen rays may cause inconvenience in the hands of the expert, and danger in the hands of the ignorant, can not be disputed. But it is the same with all other inventions; it is so with anaesthesia, asepsis, and most drugs. The often-discussed danger of originating dermatitis is practically nil, since the time of exposure is so much shorter and usually does not need to exceed three minutes; most hands can be skiaographed in one minute. The danger from officious friends, inconsiderate or malicious connérites, and shyster lawyers, as stated in the editorial, will not be disputed. But this danger is ubiquitous and by no means represents a characteristic emblem of a Röntgen-ray case.

I am so overwhelmed with the conviction of my own liability to err without the help of the rays that I have adopted the principle of declining to treat any fracture unless I have been given the privilege of taking a skialogram first. I certainly do not regard such skialographic

out by brother practitioners, it is our duty to be extremely charitable, and never to pass a hasty adverse judgment upon their handiwork; for it is just possible that when the case was first seen it was surrounded with difficulties of which at that time we can know nothing, and that the care and skill bestowed on it were worthy of a better issue,” can not be repeated too often.

There is none better able to speak of his own errors than the surgeon who sees his errors demonstrated over and over again by the rays. It is somewhat like the diagnosis of a complicated abdominal lesion before and after laparotomy. So he who has the largest and most positive experience will always be most charitable. But, while it is understood that it is the imperative duty of all of us, whether more or less experienced, to cover our brother’s mistakes before a pitiless and thoughtless public, we should not hesitate to expose our mistakes among ourselves, so that all of us may be able to recognize our errors. Then we shall not so much need to appeal to charity. And he who guards his brother from errors does more than the one who only pardons him.

Phenacetine in Acute Endocarditis.—Dr. J. Howe Adams (Medical Times, September) records the case of a woman suffering from acute endocarditis with severe pain, chills, high temperature, and the usual physical signs well marked. She was successfully treated with phenacetine in doses of a grain and a quarter. The frequency of administration is not stated.
THE PHYSIOLOGICAL ACTION AND THERAPEUTICS OF GUAIAMAR, A DERIVATIVE OF GUAIACOL.

BY GEORGE F. BUTLER, Ph. G., M. D.,
PROFESSOR OF MATERIA MEDICA AND CLINICAL MEDICINE,
COLLEGE OF PHYSICIANS AND SURGEONS;
MEDICAL DEPARTMENT, UNIVERSITY OF ILLINOIS;
ATTENDING PHYSICIAN, COOK COUNTY HOSPITAL, ETC., CHICAGO.

Undoubtedly the greatest advance in therapeutics during the past century has been the discovery and introduction to the medical profession of anaesthetics and antiseptics, and, of the two, probably the latter agents have been of more real value to mankind than the former. In this one great group of antiseptics, too, may be found some of our most valued antipyretics and hypnotics. The phenol group no doubt occupies the foremost position, for in it are found many invaluable remedies.

Phenol and its derivatives are antizymotics, antiseptics, antipyratics, disinfectants, and deodorants. Some of them belong to all these classes, but generally one or other action predominates. The spread of infectious diseases has been greatly lessened by drugs of this character, while, as is well known, the danger attending surgical operations has been diminished by their use to an almost incredible extent. This, of course, implies the local application of these remedies, but many of them are of equal value as internal antiseptics. As the principal object of this paper is to discuss internal antiseptics, particularly members of the phenol group, and more especially creosote and its derivatives, I will briefly discuss first the action of creosote itself.

Creosote is a mixture of phenols, chiefly guaiacol and cresol, obtained during the distillation of wood tar, preferably from beech. Externally it is a local anaesthetic, and, applied in full strength to animal tissues, acts as a caustic, but does not produce vesication. In weaker solutions it produces a burning and reddening of the skin. It acts more severely upon mucous membranes. It coagulates albumin and therefore its caustic action is limited. It is an antiseptic, disinfectant, deodorant, and parasiticide.

Internally, in small doses, it is cooling and sedative to the stomach, but in large or poisonous doses it is a powerful gastro-intestinal irritant. Poisonous doses also depress the heart and lower arterial tension, and markedly depress the cerebrum and respiration; small or medicinal amounts have no effect upon the circulatory, nervous, or respiratory systems, but tend rather to stimulate than otherwise.

The drug is probably eliminated by the bronchial mucous membrane and by the kidneys as guaiacol sulphate and cresol-potassium sulphate. The creosote preparations and derivatives, of which there are many, differ in some respects in their physiological action from the drug itself. Guaiacol, of which creosote contains from sixty to ninety per cent., is not caustic when applied in full strength. Guaiacol possesses marked antipyretic, diaphoretic, and diuretic properties. It is readily absorbed through the unbroken skin and rapidly reduces febrile temperature when applied in this manner. It is excreted by the sweat, saliva, and urine, but is only slightly thrown out by the exhaled air, though small amounts of the drug have been found in the lung tissue. As it is eliminated as a salt of ethyl-sulphuric acid, it must combine with albuminous bodies in the blood and chiefly through the sulphur present in the albumin molecules. It can be found in the urine fifteen minutes after administration or external application, in the form of a substance giving the reaction of phenol. It is more agreeable to the stomach than creosote and occasionally improves the appetite, though to many patients it is very disagreeable and acts as an irritant.

Though the above-named drugs are antiseptic when brought into contact with germs, they form, however, non-antiseptic compounds during the process of absorption and are inert so far as their further action on bacteria is concerned. Moreover, Hockscher has proved that even by very large doses of guaiacol the blood can not be rendered sterile. The toxic albumins, microbial products, however, combine with these drugs in the blood and are probably rendered innocuous, being oxidized and eliminated as above stated as guaiacol sulphate and cresol-potassium sulphate. Yet, owing to their corrosive and irritant action, chemists have endeavored to effect such combinations of creosote and guaiacol as to modify some of their disagreeable and objectionable actions without impairing their antiseptic properties. Their efforts usually have been in the line of combining the phenols with certain organic acids, bismuth, barbitonic acid, etc. The result has been that in the majority of cases insoluble substances have been formed which are broken up into their respective constituents in the intestines. Many of these compounds are, however, exceedingly valuable medicaments, notably benzo-sul (guaiacol benzoate), guaiacol carbonate, guaiacol salicylate, etc. In February, 1897, I published an article on benzo-sul, and have had no reason to regret it, since that, as well as the other preparations mentioned above, have proved to be valuable remedial agents.

Both benzo-sul and guaiacol carbonate are decomposed only in the intestinal canal, where the guaiacol is liberated and exerts its peculiar medicinal effect. The decomposition of these drugs ordinarily is slow, the absorption therefore of the guaiacol being correspondingly tardy and imperfect, a material portion often passing through the bowels without effect.

Starting from crude creosote, steady advancement has been made, and each new product has possessed some advantages over its predecessor by eliminating at least some of the disadvantages of the former derivatives. A knowledge of the action of creosote and guaiacol will show that their uses are necessarily limited, owing to
their irritating action. Guaiacol, however, was an advance over creosote and in a measure overcame the objectionable features of the latter, but not to the desired extent. The combination of guaiacol with carbolic and other acid radicles soon followed, and undoubtedly had many advantages over the uncombined guaiacol. As before stated, all these combinations are insoluble in water, and absorption of them is possible only after the substances have been resolved in the intestinal canal into their free constituents. In the same manner salol, which is the phenol salicylic acid ester, has to be decomposed into the free phenol or carboxylic acid and free salicylic acid before it can act. This decomposition takes place in the duodenum, but not always and not regularly. Thus it was found that the stomach of a person who had died of cholera contained all the salol which had been administered during the two days preceding death. Retention of such a quantity of a drug is, however, a serious matter, not only because of the fact that its beneficial effects have not been realized, but also from the fact that the sudden decomposition of such large doses may cause poisoning, and thus injure the reputation of the drug.

Dr. Endemann, who is the inventor of the glycerol ethers of phenol-like bodies, reasoned as follows: The methyl and ethyl ethers of phenols showed properties different from the original phenols, due to their greater stability, probably aided by their slight solubility in water. The combinations of phenols with acid radicles were insoluble in water and showed absolutely no action until decomposition had occurred. A more soluble ether, it was thought, should present not only greater facilities for absorption, but, owing to the fact that it is easier to resolve into its constituents, must more nearly preserve the physiological properties of the original phenols. Such he found to be the glycerol ether of phenols. The glycerol ethers are soluble in water, and generally more so than the phenols from which they are derived. The acrid taste of the phenol is missing and is supplanted by a pure bitter; they are therefore easily administered. The inventor has ascertained that they are readily absorbed into the system, not only through the alimentary canal but through the skin, and consequently allow the medication of the body by way of the skin. The phenols preserve thereby many of their physiological properties, and, inasmuch as they do not affect the sound tissue, the dissolution of the glycerol ethers must occur at the place where their action is needed—i.e., at the location of the diseased tissue. This is considered one of the greatest advantages of the glycerol ethers.

In presenting this glycerol ether of guaiacol to the medical profession, the name of guaiamar has been adopted.

It is a definite chemical prepared by the reaction taking place between pure guaiacol and anhydrous glycerin, according to the following equation:

\[
\text{C}_6\text{H}_4\text{OII} + \text{C}_3\text{H}_2\text{O}_3 = \text{C}_6\text{H}_4\text{OC}_3\text{H}_2\text{O}_2 + \text{H}_2\text{O}.
\]

Guaiamar is a dry, white, crystalline powder, having a melting point at 75° C., soluble in alcohol, chloroform, ether, glycerin, and in about twenty parts of water at ordinary temperature. It is neutral to test paper, non-hygroscopic, and possesses a bitter, aromatic taste. The drug is compatible and may be advantageously administered with quinine, cod-liver oil, nalt, hypophosphites, and pepsin.

In a pure state guaiamar has antiseptic properties, but its chief value lies in the liberation of nascent guaiacol, partly in the stomach, but chiefly in the intestinal canal. This decomposition is presumably caused by contact with putrefactive matter, which at the same time induces resorption of one molecule of water, liberating also glycerin, according to the following equation:

\[
\text{Guaiamar.} \quad \text{Water.} \quad \text{Guaiacol.} \quad \text{Glycerin.}
\]

\[
\text{C}_6\text{H}_4\text{O}_4 + \text{H}_2\text{O} = \text{C}_6\text{H}_4\text{O}_2 + \text{C}_3\text{H}_2\text{O}_3.
\]

The drug does not interfere with the normal process of digestion, but, on the contrary, has decided tonic action, so that patients suffering from impaired nutrition usually show marked signs of improvement under the administration of guaiamar. The drug may be given internally in doses of from three to fifteen grains; should no irritation of the genito-urinary tract occur, it can safely be given in doses of ten or fifteen grains three times a day.

It is nearly a year since this drug was first brought to my attention by the Mallinckrodt Chemical Works, since which time I have employed the remedy in numerous and varied cases, and the very satisfactory results which have followed its administration in the majority of instances indicating a drug of this character prompt me to state unqualifiedly that we have in guaiamar an antiseptic remedy fully equaling, if not surpassing, in certain particulars, any other member of the phenol group.

During the past year, in private practice and in the Cook County Hospital, I have employed guaiamar in the treatment of twenty cases of typhoid fever exclusive of any other remedy; and while, perhaps, this is too small a number upon which to base an opinion of the value of any particular medicament, I can say that whether due to a fortunate coincidence or not, each one of these cases ran an unusually mild course. It is true, I resorted to the cold-water bath in each instance for the reduction of temperature, but in comparing these patients with others where no therapeutic measure was employed but the cold bath, I am satisfied that those to whom guaiamar was given did not have so high a temperature, while in every way the general symptoms were less severe. In none of the twenty cases was there any intestinal hemorrhage or marked tympanites, and the condition of the nervous and digestive systems was, for the most part, excellent. One noticeable feature in
nearly every case was the inodorous condition of the stools after guaiamar had been administered for two or three days.

I herewith append three histories and temperature charts of patients who were treated with guaiamar, cold sponging being employed whenever the temperature reached 102.5° F. Some of the twenty cases did better than these, while some did not so well. I have aimed to select what I consider the average case:

**Case I.**—D. J. F.; nativity, United States; aged thirty-three years; occupation, laborer; civil state, married.

Uranalysis: Color, light amber; reaction, acid; specific gravity, 1.028; no albumin, no sugar, no casts, diazo present.

Present illness began five days ago with pain all over body; had been suffering from a "cold" with cough, discharge from nose, etc.; expectorates a yellowish mucus-pus. No chill, no pain in chest or abdomen, no epistaxis. Appetite good, no gastric disturbance; bowels constipated—has had to use cathartics each night since sickness began. Has been confined to bed four days.

Previous illness: Diphtheria, scarlet fever, etc., when young; had gonorrhea four years ago.

Uses a considerable quantity of tobacco, cigarettes, and drinks moderately of beer.

**Case II.**—R. W.; nativity, American; aged twenty-eight years; occupation, mechanic; civil state, single.

Uranalysis: Color, amber; reaction, acid; specific gravity, 1.082; no albumin, no sugar, no casts, diazo present.

Present illness: Was taken sick eight days ago; at that time noticed a soreness beneath the sternum and had a cough, but no expectoration; complains of having felt weak and unfit for work, but outside of this weakness and cough had no special ailment; bowels have been constipated, but was given medicine to move them; had no appetite; says that he has suffered from backache; no tenderness or pain in abdomen.

Previous illness: Had lung fever when six years of age; had several attacks of grippe; had gonorrhea three or four years ago; uses tobacco and drinks moderately.

Family history negative.

Physical examination: Mind clear, body well developed and nourished; skin warm, moist, no eruption except a few rose spots on abdomen; cheeks flushed; abdomen, few rose spots, no tenderness on pressure; liver negative; spleen palpable, but not tender; lymphatics, genitalia, and extremities negative; pa-
tient does not appear to be suffering pain; pupils unequal, right > left, react to light and accommodation; tongue slightly covered over back and centre with moist, whitish fur. Respiratory system: Chest development and expansion good; expansion detected by percussion; breathing natural; palpation, percussion and auscultation negative. Circulatory system: Pulse irregular and rather weak, arteries negative; heart, apex beat seen and heard in fifth, a little to the left of the mammary line; percussion, relative dullness. Upper border, third rib; left border, an inch to the left of the nipple; right border, half an inch to the right of the sternum.

Auscultation: Soft, blowing, systolic murmur heard at apex and transmitted toward axilla; not heard in back; second pulmonic sound accentuated.

Case III.—W. W.; nativity, American; aged fourteen years; occupation, clerk; civil state, single. Uraanalysis: Color, straw; reaction, acid; specific gravity, 1.020; no albumin, no sugar, no casts, dıazö reaction.

Present illness: Began to feel badly ten days ago; complained of dizziness and headache at the time; legs and arms ached; appetite good; bowels constipated; continued at work until six days ago, when he went to bed and has been confined there since. His mother states that there has been some tenderness in abdomen, which the child located in the left hypochondriac region. He says there has been borborygmus present for several days. Very light cough; throat is dry and soreness noticed in swallowing; has feeling of tightness in chest, which is more marked at some times than others.

Previous illness: Has been a healthy child, having had only whooping-cough and measles.

Family history negative.

Physical examination: Mind clear; development and nutrition fair; cheeks flushed; does not appear to be suffering pain. Skin: No eruption except on abdomen, where there are two or three rose spots. Eyes: Pupils react to light and accommodation. Tongue coated with heavy, brownish fur. Respiratory system: Chest development and expansion fair. Circulatory system: Pulse accelerated, full, and bounding (dielotic); arteries and heart negative. Abdomen: Slight tenderness on pressure in right iliac fossa; no distention; two or three rose spots visible. Liver negative; spleen palpable; but not tender. Lymphatics, genitalia, and extremities negative.

I have tried guaiamar in acute articular rheumatism, but always in conjunction with the salicylates, so that I am unable to state positively whether the drug possesses any specific action in this disease. Of one thing, however, I am thoroughly convinced: that an ointment of guaiamar, two drachms to one ounce of lanolin, applied to the affected joints, the joints being incased in cotton and bandaged, greatly lessens the suffering.

The following prescription I have used with marked success in several cases of gonorrheal arthritis:

R Guaiamar .................. 5 ij;
Unguenti belladonna { à d} 5 iv.
Unguenti hydrargyri  

M. et sig.: Apply freely to affected joint, gently rubbing it in, and cover with cotton and bandage.

Like cresote and certain other of its derivatives, guaiamar is of great value in certain pulmonary diseases. It has proved peculiarly efficacious in my practice in the treatment of chronic bronchitis, bronchectasis, and broncho-rheuma, and I have found it a valuable expectorant in broncho-pneumonia. It can be relied upon as an efficient stimulant expectorant, and, owing to its powerful antiseptic properties, it serves a useful purpose to correct febrile expectoration.

I have recently adopted the administration of guaiamar in pneumonia, but at this writing have not tested it on a sufficient number of cases to warrant any comment, though I expect soon to be able to say something definite in regard to its action in this disease.

In the treatment of pulmonary tuberculosis, cresote and its derivatives have probably superseded all other remedies. My experience with guaiamar in the treatment of tuberculosis has been very satisfactory. There is no question in my mind that the drug is specially valuable in the initial stages of the disease, and even in the later stages it exerts a favorable action on the night sweats, cough, and expectoration.

The advantage that guaiamar has over cresote, guaiacol, and other of its derivatives is that, owing to its marked stomachic properties, it stimulates the appetite and digestion and thereby increases weight. In one case of erysipelas of the face I gave the drug internally in five-grain doses, three times a day, and applied the following prescription locally to the affected area:

R Guaiamar .................. 5 iv;
Glycerini .................. 5 iv;
Aque .................. q. s. ad 5 iv.

The patient improved rapidly, and, judging from its effects in this case and the influence that cresote is known to have in septie diseases, I believe that we have in guaiamar a remedy of considerable value in certain septic cases, such as puerperal fever, erysipelas, etc. It would be interesting to know the expe-
rience of physicians in the use of guaiamar in these cases.

As a dressing for bedsores, I have found the following prescription extremely beneficial:

R. Guaiamar
Balsami Peruviani a
Unguenti zinci odi 

This ointment, or simple guaiamar ointment, sixty grains to one ounce, is equally serviceable in the treatment of indolent and sloughing ulcers burns with excessive suppuration, and phagedenic ulcerations generally. The remedy in these cases may be applied in the form of an ointment in solution, in water, or in alcohol and water. A solution of guaiamar makes an excellent antiseptic wash or gargle for syphilitic lesions. It is unirritating in aqueous solutions, and can be applied to open wounds with beneficial effect.

I have employed the drug considerably for its local antiseptic action, and can unhesitatingly recommend it for all the conditions above mentioned.

In three cases of chronic cystitis I have given guaiamar with good success. It is a powerful genito-urinary antiseptic and prevents the decomposition of the urine. The drug will not, however, counteract the excessive alkalinity of the urine present in many cases of cystitis so quickly as guaiacol benzoate. Moreover, it is more irritating to the genito-urinary tract than benzosol, and, while the action of guaiamar is perhaps not so rapid and decided in cystitis, it is superior to benzosol as an internal remedy in chronic gonorrhoea, blennorrhoea, and gleet. It is well to state, however, that some persons have a peculiar idiosyncrasy in regard to this drug, the remedy occasionally producing a sensation of burning during urination, and quite a good deal of irritation.

In gastro-intestinal disorders guaiamar is an invaluable remedy. Theoretically, a drug to be an ideal intestinal antiseptic must be insoluble, or at least undergo no change, in the stomach; and, if its antiseptic action is desired in the large intestine, it must be non-absorbable from the small intestine. This opinion as to the insolubility of drugs designed for intestinal antisepsis is certainly erroneous. We are all familiar with the action of corrosive chloride of mercury as an intestinal antiseptic. The drug is freely soluble, yet when given in solution it is doubtful if there is any better remedy in the treatment of chronic diarrhea. Brandly, which is readily absorbed from the stomach, exerts a decided astringent or constipating action upon the bowels, as is well known by every physician and layman. So, with guaiamar, which, though freely soluble in water, exerts a decided and powerful antiseptic action in the intestines. Its effect in typhoid fever alone proves this fact conclusively. In a perfectly healthy, normal stomach, it is doubtful if guaiamar undergoes any change; yet when there is gastric fermentation as the result of saprophytic bacteria, the fermentation and putrefaction decompose a portion of the guaiamar, liberating guaiacol, checking the development of the microorganisms, and consequently the fermentation and resulting symptoms. The drug, therefore, is both an efficient gastric and intestinal antiseptic.

I have been able to check fermentation in several cases of dilatation of the stomach better with guaiamar than with any other drug I have ever used. The advantage which the drug possesses in disorders of the stomach accompanied by marked fermentation is that, owing to its bitterness, it acts like vegetable bitters.

Not only is guaiamar a powerful antiferment, but it also stimulates peristaltic action and increases the blood supply and consequent absorption. Being an antiferment, it checks both physiological and pathological fermentation. Whereas ordinarily antiseptics as well as vegetable bitters should not be given during the active process of digestion, yet in many disorders it is absolutely imperative to give something to prevent decomposition and fermentation. Of course, in the treatment of these diseases other procedures should be instituted; but it is my intention in this paper only to call the attention of the profession to guaiamar as an antiseptic remedy in various diseases.

Self-intoxication resulting from intestinal indigestion in the majority of cases may be prevented by the free administration of guaiamar.

In the diarrhoeas of children and infants, especially the diarrhoeas peculiar to the heated term, and produced by bacteria, there is no better drug than guaiamar to prevent decomposition in the intestines. In addition to cathartics and flushing of the bowels, I invariably prescribe some intestinal antiseptic in cases of acute dyspeptic diarrhoea, and since my attention has been called to guaiamar I have employed it in a number of cases of this character with unexpected and most satisfactory results.

In calling the attention of the profession to this valuable remedy, I have recorded only my personal experience with the drug in private and hospital practice, which had been so auspicious that I can conscientiously and without reserve recommend guaiamar as a remedy possessing a wide range of usefulness, probably surpassing any of the other derivatives of guaiacol.

I fully realize the responsibility I assume in so emphatic an indorsement of guaiamar. Physicians who may have been induced to prescribe benzosol and kryofine from my recommendation of them during the past two years I am sure have had no cause to regret it, nor do I believe that any physician who will faithfully give guaiamar a fair trial in cases which seem to call for a drug of this character will be disappointed, but, on the contrary, will feel that an exceptionally valuable drug has been added to materia medica.
THE COMPULSORY REPORTING OF TUBERCULOSIS.

By S. A. KNOFF, M.D.

The prosecution of Dr. Ernest L. Shurly, of Detroit, for failing to report a case of tuberculosis, and the intention of bringing the matter before the supreme court in order that a test case may be tried, has brought this difficult and delicate matter anew before the medical profession and the laity. That such a controversy could ever be productive of any good, or raise the esteem which the laity should have for the medical profession and the boards of health, I doubt very much. On the contrary, I am convinced that the cause of solving the tuberculosis problem through judicious prophylactic measures must suffer thereby to an alarming degree.

I have in previous writings, and also in my recent book on tuberculosis, briefly stated my views on this subject; but at the last year's meeting of the State and Provincial Boards of Health of North America, which was held in Detroit, the very city where this controversy is now going on, compulsory reporting of tuberculosis was discussed at length. In view of the importance of this question to the general profession, and I may also add, in the hope that my feeble efforts may aid to bring about a peaceable solution of this vital problem, I venture to reproduce here textually what I said then, which represented what in my somewhat extensive experience with pulmonary invalids seemed to me the proper course to pursue.

I copy the following from the stenographic report of the proceedings of the thirteenth annual meeting of the Conference of State and Municipal Boards of Health of North America:

"When I was younger and less experienced I was in favor of a measure making the reporting of pulmonary tuberculosis obligatory on the part of the general practitioner, on the same ground that he should report cases of small-pox, yellow fever, diptheria, etc. Riper experience has changed my opinion in this respect. My reasons for this are as follows:

"1. Pulmonary tuberculosis is not a contagious disease, but only communicable; the contact per se of a consumptive individual does not transmit the disease.

"2. The scrupulous care and destruction of tuberculous expectoration and other secretions suffices to do away with all danger of infection and transmission.

"3. Pulmonary tuberculosis is a chronic disease, lasting often for years, and once reporting it at a given time, and even the one and usually only visit on the part of a sanitary inspector, can have no lasting effect in the prevention of tuberculosis.

"4. The tuberculous patient who is likely to propagate his disease in the most extensive and dangerous way is not the consumptive unable to move about, and confined to one or a few rooms, but the relatively well tuberculous individual who, though expectorating daily millions of bacilli, is often still able to attend to his occupations. Such a person, even when his case has been reported to the board of health, and when he has been visited twice or thrice by the sanitary inspector, can change his residence, and none of his neighbors will have an idea of the danger they are in if the newcomer is unscrupulous with his expectoration.

"5. While some boards of health refrain from sending a sanitary inspector when this is expressly stated as undesired in the family physician's report, some boards maintain that it should be done in all cases. Only the physician, who in many cases is not only the medical adviser but also the counselor and intimate friend of the family, will know that circumstances arise where the making public of the existence of a tuberculous disease in a family would mean disaster.

"What, then, would remain to be done by the sanitary authorities in regard to this matter?

"In the interest of demographical science, and in the hope of discovery of some of the underlying causes when the disease is seemingly confined to certain districts, all cases of tuberculosis should be reported. The reporting physician should receive printed measures how to insure a thorough prophylaxis, and also an offer that, if desirable, the sanitary inspector would visit the patient for the verbal instruction. It should be left to the discretion of the physician when and how often a disinfection of the patient's apartments during the course of his disease should take place. The disinfection of an apartment in which a consumptive person has died must, however, be enforced by law, and the physician should be held responsible that the authorities are notified of such a death. A disinfection should also be obligatory in case a room is vacated by a consumptive person; this should be especially enforced in the case of hotels, boarding houses, and health resorts. There should be no charge for disinfecting for the poor.

"One of the vital duties of the board of health should be to inspect regularly all institutions which admit cases of pulmonary tuberculosis for treatment and care, and to insist upon a systematic carrying out of all the necessary precautions concerning prophylaxis. Only one who has visited, as I have done, many of the so-called 'homes' or hospitals for consumptives, some even sitting under the name of sanatorium, where there is often not even a visiting, much less a house physician, can form an idea of the danger such an institution is to the community. All the hygienic and prophylactic measures, which in an assembly of consumptives require a strong will and the thorough medical knowledge of one especially trained for this task, are left in the hands of a gentle priest, minister, sister superior, or matron."

This is what I said on the 10th of August, 1898. To judge from the manner in which these remarks were greeted at the time, I believe that my opinion was then at least shared by a large number of the health officers
present. In my address on State and Municipal Care of Consumptives, which I had the honor to deliver before that distinguished body of sanitarians on the same occasion, I pleaded for a thorough cooperation of the general profession and the health authorities, without which the effectual combat against tuberculosis is an impossibility.

I renew this plea to-day with all the more earnestness since we seem to have advanced little in this matter. Dr. Mulheron goes too far if he calls the compulsory reporting of tuberculosis a "foolish fad of some theorists." The communicability of pulmonary tuberculosis through dried, carelessly deposited sputum, and also in a measure through the expulsion of particles of saliva during dry cough or while speaking, is a fact no longer to be disputed. But the way in which some health boards proceed does not seem to me the best to induce the general practitioner to cooperate with them.

Pulmonary tuberculosis is a highly communicable disease, there is no doubt about it. The only question is, should this chronic communicable disease, lasting often for years, be classed with acute infectious diseases, such as variola, diphtheria, yellow fever, etc., and is it of interest and utility to the public welfare to compel the profession to report tuberculosis and give the health department the right to interfere?

In answer to this question I may, with the permission of the editor of the *New York Medical Journal*, copy a sentence contained in an editorial on the subject in the number of September 2d: "Ever since some of the health boards began to insist that physicians should report their cases of tuberculous disease there has been, besides resentment on the part of practitioners, the feeling that, on the whole, such reports would do more harm than good, unless great tact was employed."

To instill in the hundreds of medical inspectors needed to visit all the cases of pulmonary tuberculosis in a large city the great amount of tact which would be necessary to deal, independently of the attending physician, with the afflicted friends and relatives and also the patient himself, seems to me a task beyond the power of even the best and wisest director of any health department.

But in view of the uselessness of reporting cases in many instances, the difficulty in having it done with tact where it might do some good, the annoyance, and here I agree with Dr. Mulheron, the worlds of injustice and harm it may do to the perfectly healthy relatives of the patient, and last, but not least, in view of the well-nigh impossible task of reporting all cases of tuberculosis, since perhaps one sixth of us are tuberculous in one form or another, let us by all means leave the prophylactic measures to be instituted in the hands of the medical practitioners, but especially in the hands of the family physician. Let the boards of health supply all physicians at regular intervals, or upon demand, with instructions how best to carry on a thorough prophylaxis; let all boards offer to the physicians a free bacteriological examination, a gratuitous disinfection of the patients' dwellings, if they belong to the poorer classes; let the boards distribute, gratuitously, or for a nominal price, pocket spitoons to dispensaries, hospitals, and all tuberculous patients who may apply for them; and let the inspectors visit regularly sanatoria, hospitals, asylums, boarding houses, health resorts, and all places where tuberculous patients may congregate, and see that rigorous prophylactic measures are carried out.

Should there ever be a refractory patient who absolutely refuses to comply with the instructions concerning the expectoration, every conscientious physician would consider it a duty to report such a case as dangerous and to demand isolation.

All physicians are the guardians of health, but especially so is the family physician. Let the health authorities and the general practitioner work in unison; let us create societies for the prevention of tuberculosis, and thus let us help in educating the masses. Let us ourselves be willing to learn from the experts in the health departments; let us study their circulars; let us do all we can in reporting promptly cases of acute infections and contagious diseases. But, on the other hand, let the health departments content themselves with receiving the report that at such and such a place a tuberculous case exists. And in acknowledging a report let the department send, if necessary, special instructions to the doctor, besides such general circulars as it is accustomed to deposit at the patient's dwelling. The attending physician will best know in whose hands they are to be placed in order to do the most good. Such circulars, for example, as those issued in the city of New York have done a great deal of good. Their usefulness will be increased when they reach the patient through the attending physician, who may add some verbal instructions as to their especial importance in the case in hand. Let the health department trust in this matter the intelligence of the American physician. The fair name of medical science must suffer in the eyes of the public by this perpetual warfare. Let us end it.

EXHIBITION OF A CASE OF STAMMERING, WITH DEMONSTRATION OF THE METHODS EMPLOYED IN TREATMENT.*

By G. HUDSON MAKUEN, M. D.,

PHILADELPHIA.

The patient, A. A., referred to me by Dr. Swithin Chandler, of Wilmington, Delaware, is an American, twenty-nine years of age, a college graduate, and a con-

* Read before the American Laryngological Association at its twenty-first annual congress.
A MAKEN: STAMMERING AND ITS TREATMENT.

TRACTED engineer by profession. He has stammered with varying severity since childhood, and he has noticed but little if any improvement during the last few years. His general health is fairly good, although, as you see, he is of the neurasthenic type. He had no acute infectious disease prior to the beginning of his trouble, and he did not have a fright or receive an injury of which he has any recollection. His hearing is good, and there is only a slight ocular irregularity. He had some catarrhal condition of the nose and throat, with small adhesions between the tonsils and palatal folds. There is no history of parental consanguinity, and there is in the family no consumption, insanity, idiocy, deaf-mutism, or other nervous affection.

The chief characteristic of his defect was a spasmodic contraction of the muscles of the soft palate and tongue, resulting in sudden closures, during attempts at vocalization and articulation, of what I have called the posterior palato-lingual chink. These spasmodic contractions were of variable frequency and duration, and they came at the most unexpected times. They gave the speech a peculiar jerky character, and sometimes blocked it entirely. Moreover, the defect was more pronounced in reading than in speaking, and he says that when he stammered most in reading or speaking he stammered also in other things. For instance, there was a kind of mental hesitation, and he sometimes could not think connectedly. The affection would seem to be a neurosis and to bear a close resemblance to the diseases known as hysteria and chorea.

The location of the neurosis, if we may so name it, varies in different individuals, and therefore it can be determined only by a close study of each individual case, of the kind of stammering presented, and its external manifestations in the peripheral organs of speech. Whatever may be the location of the neurosis, however, it is truth to say that no part of the nervous system employed in the use of speech and language can be entirely exempt from its influence; and to a lesser degree, perhaps, it affects the general nervous system.

The question of etiology in this case is an interesting one. We have no history of stammering ancestors, of association with others who stammered, or of nervous shock as the result of fright, injury, or the infectious diseases of childhood. In fact, there seems to have been no incident in the early life of the patient or in the life of his ancestors to which we can trace the origin of the affection. It began with the inception of the development of speech and under no apparent extraordinary conditions of environment. The child was either born with a neurosis of the motor speech tracts in the central nervous system, predisposing him to the development of the affection, or he must have acquired it between the time of birth and the beginning of the formative speech period. The theory that this neurosis was congenital is strengthened by the fact that a younger brother was saved from being a stammerer only by the most careful management. We may suppose, therefore, that both were born with a predisposition to stammer, and that this predisposition may have been transmitted by inheritance through several generations. In substantiation of this theory, it is not necessary to elicit a history of stammering ancestors, but only a history of an ancestral tendency to stammer. This history is difficult to get, although there are probably few people who have not experienced at some time or other a more or less well-marked tendency toward hesitation in speech. The disposition to stammer is more general than we suppose, and it is quite possible that more of us would yield to it if our powers of resistance were less strong.

The younger brother was successfully guided over the critical period and thus helped to escape the development of the affection; while our patient, with the same treatment, perhaps, but with less powers of resistance, succumbed to it and was held in its grasp for almost thirty years. He has been set free, but the disposition to stammer still remains, and for him to eradicate it entirely may require years of patient effort.

While the characteristic spasm of stammering was most marked, as I have said, in the posterior palato-lingual chink, the primary neurosis was located in the nerves supplying not the muscles in the region of the pharynx, but the muscles supplying the respiratory organs; and the pharyngeal spasm was secondary or reflex and due to an overflow of nervous energy from the respiratory and vocal mechanisms. A certain amount of breath is always required for the production of voice, and it is only by the accurate control of the breath that the vocal element so essential to speech can be supplied synchronously with the articulatory effort.

There was in the case under discussion what Dr. Wyllie has called a lack of promptitude in the vocal element of speech, and the stammering was the result of an attempt to articulate something which at that particular instant did not exist. It was as if the bow hand of the violinist should suddenly cease to operate simultaneously with the string fingers; and as if the string fingers should try, by increased energy of action, to compensate for the delinquent bowing. This forced and unnatural fingering has its counterpart in the spasmodic action of the articulatory and other muscles of the stammerer. In both cases there is an overflow of energy into the nerves supplying the overacting muscles, and this overflow of nervous energy is the result of an attempt to do the impossible—namely, to discourse music after the bow hand has ceased to work and to articulate voice when no voice is forthcoming. It is the effort to play, in the one instance, and to speak, in the other, that causes this overflow and its resultant spasm. The stammerer is struggling to speak, and the amount of muscular spasm is in proportion to the degree of the struggle.

In normal speech the action of the muscles is entirely automatic, and when, for any reason, one or more of the three mechanisms employed fails to perform its functions, this automatic action becomes impaired, and it is the effort to control the lagging mechanism and to bring its action into harmony with the other mechanisms that constitutes the chief difficulty of the stammerer.

In the case before us the respiratory mechanism was at fault. There was an irregular and spasmodic action of the muscles that control the breath (this could be seen, of course, only by stripping the patient to the waist), and to restore these muscles to their normal action we resorted to what may be called direct nervous muscle training. The method generally employed has been an indirect one. They both have in view the development and establishment of correct automatic muscle action. The indirect method aims to do this by leading the patient unconsciously, by means of approximately correct speech, to use the muscles properly; while the direct method endeavors to single out the muscles, the action of which is faulty, and then by voluntary exercise of these muscles establish correct action.
The advantage of the latter method over the former is that it tends to develop the nervous as well as the muscular system and to establish a volitional control over the faulty mechanism. The method by indirect muscle training leaves the patient with no sure ground to stand upon. He may be led either byjudicious exercises, or even by the tricks of the charlatan, into smooth and unannounced speech, but the slightest accident may destroy his confidence and cause a return of the trouble. Thus it is that so many relapse after having been apparently cured.

Barring some organic lesion or the development of some new pathological factor in the case, the patient before you will never stammer again, because he knows how to control that particular mechanism of speech that has hitherto been responsible for all his difficulty. He can use the respiratory mechanism with as much precision and accuracy as he can flex his forearm, and not only so, but he can will to do this. Occasionally we find one who learns to control the various mechanisms of speech, but who can not learn to will to do it at the right time; and unless this volitional faculty can be restored or developed the case is hopeless.

The essential parts of the respiratory mechanism are, first, the bony thorax, or cage, as it has been called, consisting of the ribs on either side, articulating posteriorly with the dorsal vertebrae and anteriorly with the sternum; second, the muscles regulating the size of the thorax; and third, the nerves supplying these muscles.

The muscles may be divided into two sets, according as they elevate or depress the ribs; the action of one set being in direct opposition to that of the other. The levator muscles are inspiratory and the depressor muscles expiratory, and in order that there may be a sufficient and prompt supply of breath to meet the demands of the vocal element in speech, there must be a perfect balance between these two sets of muscles, just as for good vision there must be a perfect balance in the action of the extraocular muscles, and for good voice, in the action of the extralaryngeal muscles.

In the case of our patient there was a decided lack of extrathoracic muscle balance, resulting in an irregular and intermittent breath supply. In other words, the motor power for the running of the vocal machinery of speech was defective; and it was to the mechanism supplying this motor power that our attention was directed. It was the action of the diaphragm that was specially faulty, and the first step in our treatment was an effort to bring this muscle under control of the will. Ordinarily, its action is involuntary and automatic, but a very little effort suffices to render it voluntary, and thus by practice to bring its action into harmony with that of the other important muscles of this mechanism. It must be remembered that the function of the diaphragm in the control of breath for vocal purposes is somewhat different from its function in ordinary breathing. Its slight contraction in normal automatic breathing serves to enlarge the thoracic cavity in a vertical direction, and thus it may be called an inspiratory muscle; but its stronger contraction, in addition to slightly depressing its arches, serves to pull down the ribs to a marked degree, and thus it becomes for voice production one of the chief expiratory muscles.

The downward pressure of the diaphragm upon the viscera is checked by the contraction of the abdominal muscles, and therefore these latter muscles must be trained to oppose the action of the diaphragm, and it is the perfect balance between these two opposing forces that controls the breath supply to the vocal mechanism with so great accuracy. The patient was taught, therefore, to compress the abdominal viscera by means of a voluntary action of the diaphragm and abdominal muscles and to make this compression greater or less according to the strength or intensity of the tone required. Exercises were given also for the voluntary control of both the levator and depressor thoracic muscles independently of voice or breath; that is to say, the patient was taught to pull the ribs alternately up and down by volitional effort; and then the same exercise was practiced with the use of the breath, care being taken to use only one set of muscles at a time, the other set being wholly relaxed. For instance, in inhalation, only the up-pulling muscles should be used, because the contraction of the down-pulling muscles at this time would not only interfere with a rapid and full inhalation, but it would also increase unnecessarily the required muscular effort.

The next step was to combine this newly acting mechanism with the vocal mechanism. In this process the inhalation is the same as that described above—that is, it is caused by the contraction of the up-pulling muscles only—but the exhalation, when the vocal element is added, is the result of the combined action of both the up- and down-pulling muscles, and the coordination of these two sets of muscles must be such as to regulate the breath with the greatest nicety as regards both its quantity and its strength.

When the patient was able to control the muscles of the respiratory mechanism in this manner and coordinate it with the vocal mechanism in the production of elementary sounds, he was instructed to carry the same principle into the enunciation of syllables and to use in all his speech what Alexander Melville Bell has called the method of syllabication. By one voluntary impulse for each syllable he was enabled to throw the entire machinery of speech into correct physiological action, and then, by frequent repetitions of this process, the ability to enunciate any syllable was acquired; and as soon as the patient learned by experience that he could do this he was practically cured. It only remained for him to make the entire process easy and natural by persistent practice. As you will see, he has not only overcome his difficulty, but he has at the same time acquired a more effective manner of speech.

THE EARLY RECOGNITION OF KIDNEY DISEASE, ESPECIALLY IN ITS REFERENCE TO LIFE INSURANCE.*

By T. H. ROCKWELL, M. D.

As the presence of albumin in the urine is so closely associated with degenerative changes in the kidneys, let us stop for a moment and consider some of the causes which may produce it. It may be present after excessive muscular exercise, from excessive heat or cold, indiscretions of diet, during adolescence, prolonged mental exertion, from pus or blood gaining access to the genito-urinary tract, from altered conditions of the

* Read before the Society of the Alumni of the City (Charity) Hospital, May 10, 1899.
blood, from a change in the blood pressure in the kidney, or from an inflammation in the organ itself. The question at once arises: "Does a perfectly healthy individual pass albumin?" I think all observers will agree that such is not the case, and that the presence of albumin, while it may not always mean a serious lesion, is sufficient to put us on our guard to determine if possible the true import of it. I shall not attempt to take up the discussion of acute nephritis, but limit myself to the cases which present themselves from day to day of individuals presumably healthy, especially those who present themselves as applicants for life insurance. The mere presence of albumin does not justify us in making a diagnosis of renal inflammation, even when we are satisfied that it comes from the kidney, nor is the quantity any guide to the severity of the lesion. I have frequently observed an immense amount of albumin following excessive muscular exercise, and a few hours later, after resting, not even a faint trace could be discovered.

On the other hand, the most formidable form, interstitial nephritis, may sometimes be far advanced, and some claim may even run its course, without albumin being found.

The two forms of Bright's disease which are most likely to present themselves for early diagnosis are chronic diffuse nephritis and chronic interstitial nephritis, or contracted kidney. Chronic diffuse nephritis may begin insidiously or as a sequel to the acute form. At the beginning there may be absolutely no symptoms to direct the patient's attention to the trouble, and the first intimation he has that something is wrong is when the urine is examined for some reason or other and albumin discovered.

If the disease is at all advanced the albumin is usually present in fair amount, and in the late stages becomes excessive. The specific gravity is not greatly altered and seems to vary with the amount of albumin secreted from day to day. If the quantity passed in twenty-four hours is carefully measured a diminution will usually be found. If dropsy is present, the amount of the chlorides is usually diminished and a lessened amount of urea is to be expected. The urinary sediment is abundant, and in consequence the urine is cloudy, containing granular and hyaline casts and renal epithelium.

Chronic interstitial nephritis is the bugbear of life-insurance companies, for the disease may be well advanced before it is discovered. It is usually chronic from the beginning, and its course may extend over many years. I have had under observation a number of men who have had the trouble ten or fifteen years and who are yet seemingly in good condition and show no signs of having a serious disease. These men, I believe, however, go off quickly at the end. The thing that will strike you most in diagnosticating this trouble is the constant low specific gravity. When a man over forty persists in furnishing me with urine, the gravity of which varies from 1.005 to 1.015, especially when I get it at the high tide of digestion, I expect to find hyaline casts if I look long enough for them. The urine even with this low specific gravity is usually distinctly acid, is pale and clear, containing little or no sediment, in marked contrast to the chronic diffuse form. The diurnal quantity is usually increased, and the solids and urea are diminished in quantity, although the chlorides are not diminished to the extent they are in diffuse nephritis, owing, perhaps, to the fact that anasarca is not so general. The subject often has occasion to rise at night to pass his water. Albumin may be present or absent. It is never in large amounts, and some observers state that the disease may run its course without its making its appearance. I am rather inclined to think, however, that if a sufficient number of careful tests are made it will be discovered. In such sediment as one is able to get, preferably by the centrifuge, may be found hyaline casts, cylindroids, and an occasional leucocyte. Uric acid and oxalate of calcium are fairly constant.

I usually preserve the urine with borolypotol, place a quantity in a conical glass, allow it to remain overnight, decant all but a small portion, and put the remainder in a centrifugal machine, in this way feeling fairly certain of obtaining the casts if they are present. Unless you do this you can not be sure they are not there, and you will all agree that one well-marked cast on a slide is worth, for diagnostic purposes, half a dozen slides on which nothing is found. The casts may be so few that only with the greatest care can they be discovered. In the diagnosis of this form of nephritis we are greatly aided by our examination of the heart, for hypertrophy begins early. Arterial tension is high from the beginning, and the second sound at the base is usually accentuated.

Having then observed the salient points of these two important forms of nephritis, let us determine the proper disposal of a subject for life insurance who does not present enough evidence to justify a diagnosis of inflammation of the kidney. We frequently find albumin in the urine in seemingly healthy men, and aside from this nothing abnormal can be discovered. The albumin may be constantly present or intermittent. In quantity, from a faint trace to a distinct amount; no casts, cylindroids, or renal epithelium. We exclude everything but serum albumin of renal origin, and there we are forced to stop. If we collect the urine for twenty-four hours we find the quantity passed, solids, urea, chlorides, and phosphates, nearly normal. There are no circulatory changes to help us, and we find ourselves confronted with albumin and nothing else. What does it mean? We go over all the apparent reasons as to why albumin may appear in the urine, acquaint ourselves as far as possible with the urethra and bladder, inquire as to diet, bathing, and exercise; his habits and mode of life; determine whether an altered
arterial tension can produce it; look him over for
anaemia, and find nothing to account for it. Can we
issue a policy to such a subject during the continuance
of the albumin? I know many men whom I observed
eight or nine years ago who are still living, seemingly
in good health, and to all appearances have many years of
life before them. On the other hand, many men I
have declined for just this cause and nothing else are
now dead, some from subsequent nephritis and some
from many other causes. With our present knowledge
of the subject we can not accept them, for it is the
constant experience of life-insurance companies that
these subjects do badly when they are called on to go
through any serious illness, such as pneumonia, typhoid
fever, or serious accident. The presence of albumin
may not, and certainly does not in all cases, mean
Bright's; but it does mean something. I do not be-
line that an absolutely healthy man ever passes albu-
min. The cause producing it may be a temporary one,
disappearing by itself or through proper treatment.
But as long as it is present, and for a reasonable time
after its disappearance to prove that it was accidental,
we can not be justified in underestimating its impor-
tance. The time may come when we will be able to say
that this form of albumin is of serious import and that
form benign, but until then our only safety lies in con-
sidering that its presence is a danger signal we are
bound to respect.

If we could be reasonably certain that the inflam-
mation would not extend beyond the condition in which
we find the kidney at the time of examination we might
issue some form of policy that would cover the extra
risk. By estimating the amount of urea and solids
eliminated in twenty-four hours we can form a reason-
able idea as to whether the kidneys are doing their work
or not. But we can not be certain how long the favor-
able action will continue. A sudden cold or acute dis-
eease of almost any sort might have serious consequences
in store for the damaged kidney; and when recovery
would otherwise ensue, on account of the impaired
organs, the patient goes from bad to worse and a seem-
ingly trivial affair to-day becomes a serious problem to-
tomorrow. Hence a man who is passing albumin is con-
stantly living over a volcano. It may remain quiescent
for years, or suddenly burst forth with most damaging
consequences.

It is perhaps true that as a result of an early scar-
let fever, diphtheria, or some other similar trouble a
small part of one kidney may be damaged and the dis-
eease not extend beyond a limited portion, thus causing
albumin and casts to appear in the urine. I have such
a case in mind; and I have found these things over a
period of nine years, and no doubt the trouble has
been there much longer than that. The subject is now
a man of thirty-five years and gives a history of acute
nephritis following scarlet fever some eighteen years
ago. Aside from the albumin and casts he is, as far as
can be determined, a very healthy man. He does not
show any evidence of the trouble, and his kidney lesion
seems to be decreasing from year to year. He is an ex-
ceptionally good-looking risk, but I have never felt
justified in recommending him for a policy, for one
never knows when the quiescent inflammation will take
on an active form and carry him off. It seems hard to
deprive such a man of the benefits of insurance, but it
is the only safe way for the company. I know another
man who was declined nearly twenty years ago for albu-
min in considerable amount. I have examined his urine
several times during the last few years and have never
failed to find a liberal quantity, yet he seems to be in
the best of health. He is now a man nearly sixty and will
probably live for several years, although he is in con-
stant danger, in consequence of some intercurrent dis-
ease which would put too great a task on the kidneys
for them to stand. It is such exceptional cases as these,
however, that only go to prove the general rule. It is
not usual for a man to pass albumin for so long a time
without finding other evidences of his disease. The
albumin either ceases after a short time, showing that
it was due to some temporary disturbance, or the pa-
ient proceeds to develop other symptoms of the dis-
ease.

In the early diagnosis of kidney inflammation
microscopical examination is indispensable and of great
value. Hyaline casts and cylindroids will point to con-
tacted kidney. When granular casts are also present,
accompanied with cloudy urine, much sediment, epib-
inthelium, and pus cells, the indications are strongly in
favor of the chronic diffuse form. It is this latter con-
dition that is usually seen by the general practitioner,
for the other symptoms are earlier and more pronounced,
and the patient will recognize that something is wrong
and seek advice on his own account. The other form is
more troublesome, for it is often hard to convince per-
sons that they have anything the matter, and I am sorry
to say that it has been my unpleasant observation that
they do not receive much aid from their medical ad-
viser. They go to him and say to him they have been
told they had kidney trouble. He examines the urine,
finds little or no albumin by his tests, makes a careless
microscopical examination, and tells them the doctor
is wrong, they have no disease. He frequently writes a
certificate to this effect, and armed with this the man
comes back for another interview, expecting and hoping
to get his insurance forthwith. He believes his doctor,
it's more pleasant, and leaves you thoroughly convinced
that you have done him an injustice. I remember one
man who several years ago talked about suing the com-
pany because I said he had a kidney trouble and would
not issue the insurance, when his doctor and several oth-
ers declared he was in perfect health. He argued and
stormed and was not to be convinced. I learned a short
time ago that he is now practically moribund with
Bright's. It is an important thing for the general
practitioner to be able to make careful tests of the urine. It is very easy to do, and very necessary, but I am sorry to say that it is a very frequent experience with me to read certificates of analysis from reputable men, setting forth that the urine is normal, when albumin and other abnormal products are distinctly present and in sufficient amount to be readily distinguished by the ordinary tests. I am sure your own observations will bear me out in this, especially those of you who do much insurance work. And if, when we get a chance, we can give our medical brothers a tip to be more careful, we shall be doing a good work for all concerned, especially the one most interested, the patient.

FOREIGN BODIES LODGED WITHIN THE EYEBALL.*

By EDWARD JACKSON, A. M., M. D.,
DENVER, COL.

Diagnosis.—Every penetrating wound of the eyeball should be carefully studied as a case of possible lodgment of a foreign body. The patient's account of his injury is always defective, and often misleading. Only careful cross-questioning will show how much of value there is in it. A foreign body having entered deeply does not cause the sensation of "something in the eye," and the patient, impelled by hope, is often very positive that nothing is lodged there. The diagnosis must be entirely independent of such testimony.

Every detail of the accident should be minutely investigated. If the body that indited the wound is obtainable, it should be examined to see if any portion has probably broken off and remained within the eye, or if it has probably acted as the carrier of adherent and possibly infective substances. An eyelash or even a bit of epithelium from the lid imbedded in the iris becomes the starting-point of a cyst. A slightly irregular edge or point would be very likely to introduce foreign matter, while a perfectly smooth point or edge would probably enter the eye cleanly by its passage through the sclero-corneal coat.

If the eye has been struck by a flying fragment, this should be carefully sought for. When it can not be found, inspection of the part from which it has broken will give valuable information as to its size and shape. Then the relative position of the point from which it flew, the exact attitude of the patient, and the direction in which he was looking at the instant may throw valuable light on the probable position of the foreign body.

To illustrate the possible importance of any exact observation of this kind, I may mention the case of a man sent to me from another hospital that he might have the benefit of an attempt at magnet extraction before resorting to enucleation of the eye for a fragment of steel that was believed to have lodged in it. There was a penetrating wound of the cornea and iris, and intraocular hemorrhage prevented any view of the deeper structures of the eye. From the part of the wound that perforated the cornea a deep gash into the cornea, but not entirely through it, passed upward and to the right. Careful questioning showed clearly that the foreign body had come from below and to the left. It could not have entered the eye through the perforation in the cornea and afterward have cut the gash. But it must have struck the eye a glancing blow, hard enough at first to penetrate the cornea and iris, and afterward plowed its way through only a portion of the thickness of the cornea as it passed onward. The case was treated on this supposition, which its subsequent history sustained. The patient retained a sound and useful eye, which would certainly have been damaged if it had been subjected to prolonged attempts at extraction of the foreign body, which really was not lodged in it.

Besides the careful inspection of the external wound and the anterior segment of the eye by oblique illumination, every case of foreign body in the eye should be subjected to a thorough ophthalmoscopic examination at the earliest possible moment, before increasing cloudiness of the crystalline lens, or diffusion of opacity due to hemorrhage, renders such an examination well-nigh useless. Even when the foreign body can not be seen with the ophthalmoscope its position may often be indicated by a streak of commencing opacity in the lens, or air-bubbles, or shreds of hemorrhage marking its track through the vitreous. Such signs not only show the location of the foreign body, they are of great importance in making certain that it has really passed into the eye.

When the fact of its entrance seems clear, we must also consider whether it may not have passed entirely through the eyeball and lodged elsewhere.

I have seen two cases in which this occurred. One was that of a young man struck in the left eye with a No. 6 shot. He was not seen until the ninth day, when the lens was greatly swollen, the tension of the eyeball + T. 2, and a violent iridocyclitis called for enucleation. I suspected, however, that the shot was not in the eye, because of the very clear history the patient gave of the instant complete blindness, which would be very unlikely to occur, except from a much more extensive injury of the globe, unless the optic nerve was injured. On examining the eye after removal, I found the wound of exit just at the margin of the optic nerve; the nerve had been divided. and the shot, having passed deeper, was not found.

In the other case a large piece of steel was known to have entered the eye. The patient was etherized and a careful search made for it with the electro-magnet. It was not found.

Two days later ecchymosis appeared at the upper

* Read before the Colorado State Medical Society, June 20, 1899.
and lower margins of the orbit and under the conjunctiva, and there was marked protrusion of the globe, showing that the foreign body had probably passed through the eyeball and caused hemorrhage into the orbit. Three months later, when the shrunken globe was enucleated, we found it just back of the eyeball.

The foregoing case was seen in 1892; in a similar case occurring now the X rays would certainly reveal the position of such a foreign body. This valuable aid in diagnosis should be resorted to in all cases of suspected foreign body in the eye, where the exact location of it cannot be made out by examination under oblique illumination or with the ophthalmoscope. Making two negatives with the tube placed in different positions, with some known fixed point, the shadow of which can be used as a point of reference for the shadow of the foreign body (especially by the method of Sweet), it becomes possible to determine the position of the latter with great exactness.

Unfortunately, a foreign body may be so small that it will give no perceptible shadow on the sensitive plate, and yet be large enough to cause the destruction of the eye. I have had one case in which many trials with the X rays failed to give any evidence of the presence of a small particle of steel, although it was clearly visible in the fundus with the ophthalmoscope.

Sweet, who made the radiographs in this case, has recorded another (Archives of Ophthalmology, July, 1898, p. 393) which indicates the present limits of the diagnostic value of the X rays in this direction. Only one of four negatives showed any trace of shadow of the foreign body, which on removal was found to be over one millimetre long, less than one millimetre wide, and 0.5 millimetre thick at the thickest part. Fragments smaller than this rarely strike the eye with sufficient momentum to carry them to the deeper portions. They are commonly arrested in the cornea, iris, or lens. Still we must bear in mind the possibility of their reaching the deeper structures and causing the most disastrous effects.

In considering the prognosis and treatment of eyes containing foreign bodies, it is best to divide the cases into three classes, according as the foreign body is located (1) in the iris or anterior chamber, (2) in the lens, or (3) in the vitreous or fundus.

Among twenty-five successive cases of foreign body lodged in the eyeball, the location of the foreign body was in the iris and anterior chamber in three, in the crystalline lens in four, and in the vitreous and fundus in sixteen. In one case it was partly in the iris and partly in the lens; and in the following case a foreign body, apparently simply lying on the iris, extended back through the zonule and into the vitreous.

J. D., aged twenty-three years, laborer, applied at Wills Hospital, January 8, 1898. The left eye had been struck by a flying piece of steel the evening of the preceding day. There was an irregular linear wound six or eight millimetres long across the central part of the cornea, and what appeared to be a triangular bit of steel three millimetres on a side at the lower part of the anterior chamber. An incision was made extending through the lower quadrant of the corneal limbus. An attempt to withdraw the foreign body and adjoining iris with iris forceps met with unexpected resistance. The foreign body was then coaxed out with the electro-magnet, and was found to be nine millimetres long, having extended back into the vitreous, it being only the head of the fragment that projected into the anterior chamber. The injured portion of the iris was excised, the patient placed in bed, and atropine and ice compresses used locally. The patient left the hospital at the end of five weeks with the eye quiet and vision = 3/10, in spite of the corneal scar and some opacity in the lower part of the lens and lower anterior portion of the vitreous.

Treatment and Prognosis.—When a foreign body is lodged in the iris or anterior chamber its location is usually evident and its removal comparatively easy. It should be removed as soon as possible. The only exceptions I would make to this rule are: If the seat of lodgment is in the lens, or if the foreign body has been retained for some time and the eye has become entirely quiet, and the patient can remain within reach of skilled assistance in case irritation should arise. Powder grains are occasionally lodged on the iris or in the lens. I have never seen them penetrate more deeply than this, although sometimes they have done so, and in the great majority of cases they are arrested in the cornea. When after such an accident the eye has become entirely quiet, the finely powdered charcoal that alone remains of such a grain is not likely ever to cause irritation. But such grains are at first very irritating, and the eye may be lost while one waits for it to become quiet. If seen early, these injuries should be treated as other cases of foreign body similarly situated. This is illustrated by the following case:

J. O. D., a farmer, aged twenty years, had been injured by an explosion of gunpowder the preceding day. In the right eye there was one grain of powder imbedded in the cornea, but the deeper structures were uninjured. In the left eye there were several grains of powder imbedded in the cornea and iris as well as in the conjunctiva. There was severe swelling of the lids and inflammation of the conjunctiva with purulent discharge. The cornea was generally hazy.

The patient refused to go into the hospital or to have any operation done. A solution of atropine was ordered. In four days he returned decidedly worse and was admitted to the hospital. Under general anesthesia an incision was made at the lower outer border of the cornea, five or six powder grains were picked from the front of the iris with the forceps, and about a sixth of the iris, the lower outer portion, containing several powder grains, was excised. The grains in the cornea and conjunctiva and in the lids and skin of the face were subsequently destroyed by the galvano-cautery. In fifteen days the eye was free from irritation, and subsequently obtained vision = 3/10.

It is sometimes possible to disentangle a foreign body from the iris and remove it, leaving the iris intact;
but generally it is easier and safer to do a small iridectomy, removing with the foreign body the part of the iris that has become injured or infected by it.

A foreign body lodged in the crystalline lens causes traumatic cataract. If the wound of entrance is small, several weeks, or even months, may elapse before the opacity of the lens becomes complete, and the accompanying swelling will be very moderate; but if the opening in the lens capsule is large, the opacity increases rapidly and is attended with great swelling of the lens and sometimes increased tension of the eyeball. Aside from this there is little liability of a foreign body in the lens causing serious inflammation, or an iridocyclitis, ending in a degenerated eyeball. It is proper, therefore, to allow the traumatic cataract to develop, and then to extract it in the ordinary way, being careful to make a rather large corneal incision, and, if needed, doing an iridectomy to allow the free escape of the lens mass. Taking such precautions, I have never failed to remove the foreign body with the lens mass.

If the foreign body is not thus removed the traumatic cataract will slowly shrink, and ultimately, in most cases, will be entirely absorbed, allowing the foreign body to come in contact with other structures, and perhaps cause serious damage. I have seen a chip of steel, hanging in the remains of a lens, beginning to cause serious inflammation twenty-eight years after the original injury, the eye having, according to the patient's statement, remained quiet all that time.

A foreign body entering the vitreous, and lodging there or in the retina, choroid, or ciliary body, is almost certain, if not promptly removed, to set up such inflammatory and degenerative changes as in the end render the eye functionally useless and a menace to its fellow, through sympathetic disease. In very rare cases this does not occur. Foreign bodies of moderate or small size entering through the cornea, iris, and crystalline lens are much less likely to set up a fatal iridocyclitis than those which enter more directly through the sclera. Smooth and aseptic particles, such as bird shot or splinters of glass or hot metal, are less likely to set up chronic degenerative changes; and small particles firmly fixed in the fundus are sometimes compatible with useful vision. I have met one case of this sort.

E. E. L., aged thirty-two years, express messenger. The right eye was struck with a small particle of steel twenty-one years ago. It now has vision = 2/60, tension is normal, it diverges (comitant strabismus), and has circular pupil and normal iris. There is a faint trace of opacity along the lens, with radiating opacity of the posterior cortex. The vitreous and fundus seem normal, except that the optic disc is red and hazy, and to the temporal side of it, 1.5 disc diameters from it, is a patch of chorioidal pigmentation and atrophy, in which is an irregular quadrilateral, the diameter of the disc in length and one half as wide, black, with light gray on the edges, apparently protruding in front of the retina.

The patient was shown before the Section of Ophthalmology of the College of Physicians, of Philadelphia, and all who saw it agreed that the quadrilateral mass seemed to be the foreign body. A year later there had been no perceptible change in the condition of the eye.

A few cases of this sort have been from time to time reported, and they should be taken into account when giving a prognosis or when the eye has become quiet, or is becoming quiet, when it is first seen. But they should not deter the surgeon from attempting the immediate removal of a foreign body from this region, whenever its presence and location can be certainly known soon after it has been lodged there. The chances of retaining a useful eye, or an eyeball that will not be dangerous to its fellow, are greatly improved by such removal. For particles of steel or iron, magnet extraction is the nice and scientific method of removal. But if, because of the lack of the necessary apparatus, or because of the composition of the foreign body, or the firmness with which it is imbedded, magnet extraction is impossible, if the location of the foreign body is accurately known, I believe we should always attempt its removal with scoop or forceps.

The details of such removal must be specially adapted to each individual case; there is no time now to discuss them. But this one point I would insist on: With the foreign body should be removed all badly damaged or probably infected tissue—the track of the foreign body through the vitreous, and the bed of tissue in which it lies. This can only be accomplished through a free scleral incision, made if possible through the point of entrance. Half the vitreous may be lost in a cataract extraction without serious consequences, and equally large losses of vitreous will be quite as harmless in these cases if we can only eliminate infection.

If we can save ten or fifteen per cent. of useful eyes by the extraction of the foreign body with the magnet, as heretofore generally practised, we can save two or three times as many by the careful application of well-known surgical principles to these injuries. To make a chip of steel jump from the wound of entrance with a giant magnet may seem a very brilliant operation to the bystanders, but it is a very useless one to the patient if it leaves a track of infection within the eye certain to result in its ultimate destruction. Surgery has no place for "successful operations" that work no permanent benefit for the patient.

PISTOL-SHOT WOUND OF THE ABDOMEN PERFORATING THE STOMACH.

RECOVERY.

By J. N. LE CONTE, M. D.,
HOUSE SURGEON, JERSEY CITY HOSPITAL AND DISPENSARY.

W. C., a man of forty-four years, was admitted to Jersey City Hospital, June 22, 1899, at 10.30 p. m., half an hour after receiving a pistol-shot wound of the
Therapeutic Notes.

Ammonium Chloride in Trigeminal Neuralgia.—The use of sal ammoniac in neuralgia is not new; it has been resorted to particularly in ovarian neuralgia. Still, it is well deserving of mention. In the August 10th number of Treatment, Dr. Harry Campbell says that his favorite prescription for neuralgia of the fifth nerve is the following:

\[
\begin{align*}
R & \quad \text{Ammonium chloride} \quad \frac{1}{4} \text{ drachm}; \\
T & \quad \text{Tincture of gelonium} \quad \frac{1}{4} \text{ minims}; \\
T & \quad \text{Tincture of aconite} \quad 1 \text{ minim}; \\
E & \quad \text{Fluid extract of licorice} \quad 1 \text{ drachm}; \\
W & \quad \text{Water, enough to make} \quad 1 \text{ ounce}. \\
\end{align*}
\]

M. This amount to be taken every hour, when the pain comes on, till three doses have been taken.

For Menorrhagia.—According to the Revue médicale for August 2d, M. Robin advises that where the menses anticipate the period and are prolonged beyond the ordinary term there be taken at the two principal meals eight days before the proper menstrual period from one to three coffeespoonsfuls of the following preparation:

\[
\begin{align*}
E & \quad \text{Elixir of Gurus} \quad 1,500 \text{ grains}; \\
E & \quad \text{Fluid extract of hy-} \\
& \quad \text{dristis, of each} \quad 90 \text{ "} \\
E & \quad \text{Fluid extract of vi-} \\
& \quad \text{burnum,} \\
M. & \end{align*}
\]

This medication is to be discontinued from the day of establishment of the menses, and to be resumed on the fourth day if the menstrual flow is prolonged.

Hayem's Artificial Serum in Malignant Syphilis.—Augagneur (Annales de dermatologie et de syphiligraphie, 1889, No. 5: Monatsberichte über die Gesammtleistungen auf dem Gebiete der Krankheiten des Harn- und Sexual-Apparates, iv, 8) has employed in two cases injections of the following solution with good results:

\[
\begin{align*}
R & \quad \text{Sodium chloride} \quad 7 \text{ parts}; \\
R & \quad \text{Sodium phosphate} \quad 2 \text{ "} \\
R & \quad \text{Water} \quad 1,000 \text{ "}. \\
M. & \end{align*}
\]

Whether it acts by exciting diuresis or by promoting leukocytosis is uncertain, but the more pronounced are the fever and diuresis that follow, the more energetic is the therapeutic action. Augagneur gives four or five subcutaneous injections, of from twelve to fifteen ounces each, at intervals of five or six days.

An Application for the Earache of Influenza.—Noquet, of Lille (Semaine médicale; Gazette hebdomadaire de médecine et de chirurgie, July 23d) recommends this preparation:

\[
\begin{align*}
R & \quad \text{Poppy heads} \quad \text{No. 5}; \\
R & \quad \text{Water} \quad 5,500 \text{ grains}; \\
R & \quad \text{Boil down to fifty cubic centimetres, filter, and add:} \\
& \quad \text{Chloral hydrate} \quad 7\frac{1}{4} \text{ grains}; \\
& \quad \text{Morphine hydrochloride} \quad 3 \text{ "} \\
& \quad \text{Resorcin} \quad 15 \text{ "}. \\
M. & \end{align*}
\]

A few drops are to be instilled into the ear, and relief is to be expected in from fifteen to thirty minutes. After several instillations the pain sometimes disappears entirely.

A Syrup for Psoriasis.—According to the Riforma medica for July 19th, Brocq recommends:

\[
\begin{align*}
R & \quad \text{Arsenate of sodium} \quad \frac{7}{8} \text{ grain}; \\
R & \quad \text{Salicylate of sodium} \quad 45 \text{ grains}; \\
R & \quad \text{Bicarbonate of sodium} \quad 120 \text{ "} \\
R & \quad \text{Syrup of gentian} \quad \frac{1}{4} \text{ of each} \quad 1,875 \text{ "} \\
R & \quad \text{Syrup of soapwort} \quad \frac{1}{4} \text{ of each} \quad 1,875 \text{ "}. \\
M. & \end{align*}
\]

A soupspoonful after every meal.

For Chloroanæmia.—The Riforma medica for July 18th gives the following on the authority of Baccelli:

\[
\begin{align*}
R & \quad \text{Artemisia} \quad \frac{7}{8} \text{ grain}; \\
R & \quad \text{Crystallized quassine} \quad \frac{7}{8} \text{ "} \\
R & \quad \text{Protoxalate of iron} \quad \frac{1}{4} \text{ "} \\
M. & \end{align*}
\]

For a lozeng. Four may be taken daily, two before each principal meal.
HOSPITALS FOR CONSUMPTIVES.

A most important addition to the recent literature of the prevention and treatment of pulmonary consumption is Dr. Knopf’s Alvarenga prize essay entitled Pulmonary Tuberculosis: its Modern Prophylaxis and the Treatment in Special Institutions and at Home. In our issue for September 2d we gave a brief notice of the book—all that our space would admit of—but it is worthy of further mention. The essay treats of a multitude of matters intimately connected with the problem of overcoming the disease, and with all of them in a most interesting way, but we must content ourselves here with calling attention to but one of them, the author’s ideal of a hospital for consumptives.

Dr. Knopf declares his disbelief in the specific anti-philthical action of any particular climate, and he would, therefore, place the hospital within easy reach of some large centre of population. At the same time, he would pay attention to atmospheric conditions, and would have his institution in a situation free from miasm, with the extremes of temperature not too pronounced, and, if the region admits of it, at a height of from a thousand to fifteen hundred feet above sea level. He would also seek for it the protection against cold winds of higher hills or a wooded country, preferably a pine forest. To show that special climatic conditions are not really necessary to the achievement of noteworthy results, he cites the Sharon Sanatorium, near Boston, and the Chestnut Hill Hospital for Consumptives, near Philadelphia, for neither of which can any such conditions be alleged.

As regards the buildings, the author would avoid on the one hand the large aggregations found in some European institutions, fearing that they would hamper hygienic measures, and on the other hand the small cottages of the American plan, on account of the difficulty of administering them with due regard for economy. He gives detailed plans prepared in accord with his designs by Professor Van Pelt, of Cornell University, and they seem to us to be not only suitable for the object primarily sought for, but also susceptible of satisfactory elaboration from the architect’s point of view. All the buildings that would form essential parts of the hospital would be connected by protected galleries, and there would be two independent houses, one for the residence of the professional and administrative officers of the institution, and the other for the accommodation of persons who came to visit the patients.

Dr. Knopf gives details for the administration of such a hospital, all worked out with particular reference to the saving or prolonging of life in cases of pulmonary consumption and to preventing the disease from spreading. A notable point in promoting the last-mentioned object rests on the thesis that, to stamp out tuberculous disease among human beings, we must first exterminate it among brutes. It follows, as Dr. Knopf insists more pointedly than most writers, so far as we can call to mind, that the infected refuse of a hospital must be so disposed of that the domestic animals can not get access to it. This may seem like a small matter, but to us it appears one of great importance, and we mention it as exemplifying the comprehensiveness of the author’s study. In our opinion, his essay ought to serve as an incitement to very great improvement in our methods of dealing with consumption.

THE “FLEXION” STYLE OF MARCHING.

This is a new style of marching which has been introduced into the French army. For a description of it, together with some account of the benefit thought to result from its employment, we are indebted to the Army and Navy Journal, which, in its issue for September 9th, says: “The style is so new that there is no text-book on the market as yet, but several French writers give the following general idea of the body movements: The knees must be always bent; the feet lifted no higher than necessary to clear the inequalities of the ground; the advancing foot must be placed flat on the ground, the step being made neither by the toe nor by the heel. The footfall should be noiseless, and the steps at first short and frequent. The body must lean well forward, the back must be straight and the head erect, the chest open and shoulders low. It is recommended that, when at drill, a short stick be held with both hands in front of the chest. The lessons should not be more frequent than two or three times a week. A table is given of the distance to be traversed in each of the thirty-six lessons, beginning with three thousand yards and going up to twelve thousand; also showing how in the early lessons ten minutes is allowed for the first kilometre, nine and a half for the second, and seven and three quarters for the third; these times steadily diminish with each lesson, as the pace increases,
until finally the first kilometre, or five eighths of a mile, is traveled in seven and three quarter minutes, the second in six and a quarter, and the third in five and three quarters. Now, one kilometre in five and three quarter minutes is a good six and a half miles an hour.” It is added that a three months’ drill is necessary to thorough training in the “flexion” march.

The statement is made that this style of march is really a run, although we do not find it stated that the foot behind leaves the ground before the foot in advance has taken it, and it is that occurrence, not speed, that distinguishes running from walking. Whichever we may call this new style of marching, a run or a walk, some important advantages are alleged for it. Naturally, as the trunk is inclined decidedly forward, the soldier does not appear so tall as he would otherwise look, and we may surmise that when advancing in this style under musketry fire a body of men might come out with less than the usual loss, on account of the tendency of the enemy’s bullets to fly relatively more than ever too high. Dynamometric experiments are said to have shown that the foot does not press so heavily on the ground as in the ordinary style of marching, and so, it is suggested, the man has more strength left to expend in propulsion; moreover, there is less of a jar at each step, and, in place of the customary tramp of armed men, the tread is comparatively noiseless.

Two officers, two sergeants, and thirty men of a regiment were put under training at Nantes, says our contemporary, and it is reported that “after three months’ instruction, they marched, in the presence of General Fay, carrying their rifles, bayonets, one hundred rounds of ammunition per man, and food for one meal, along a hilly road, a distance of twelve miles and a half in an hour and forty-six minutes, which is at the rate of rather over seven miles an hour. Not one man fell out by the way. After a rest of two hours, they returned in three hours and five minutes, including two halts of ten minutes each, which gives an average speed of over four miles and a half an hour. Two days afterward these same men, in the presence of General Colonieu, in heavy marching order, covered a distance of six miles and seven eighths across fields on hilly ground in an hour and twenty minutes, which works out at about five miles and a half an hour. At the end of their march they were at once told off to target practice, when their shooting proved superior to that of the best company of marksmen in the regiment; this was done to determine whether the exertions of their rapid march had injured their capabilities as riflemen.”

Enough seems to have been established in favor of the new style of marching to make it desirable to try it at least with our own forces. Such a trial would be quite in line with the commendable modern idea of taxing the soldier’s strength as little as possible.

FALSE WITNESS AS THE RESULT OF SUGGESTION.

According to M. Joire, of Lille (Gazette hebdomadaire de médecine et de chirurgie, August 10th), false testimony as a result of suggestion may be divided into three categories. The first form is that of deliberate direct suggestion, such as when a person in the hypnotic state is directed to subsequently give certain evidence calculated to cause a miscarriage of justice. This condition, as the author says, if it ever really occurs, must necessarily be very rare, for it would necessitate the agency of one thoroughly skilled in hypnotism and dexterous in employing suggestion, and, moreover, a subject so sensitive as to be capable of being rapidly and without his consciousness thrown into the somnambulistic state. In the event of such a case occurring, physicians familiar with hypnotism would at once recognize the subject’s condition, and might even by skillful questioning discover the guilty person.

In the second category must be placed false witness as a result of “auto-suggestion.” Here we have only one person involved, and the suggestion, no matter from what source it arises, is given and received by the same subject. Cases of this kind are numerous, and include the hysterical and other classes of false accusation with which the medical profession is familiar to its cost.

The third type is the most important of all, and at the same time the least known. It includes those cases in which a suggestion is conveyed involuntarily and in an unconscious manner.

The author points out that it is well known how easily children are disposed to receive as true a statement which is positively asserted to them by one imposing on them. But it is not sufficiently borne in mind that many adults, not presenting in ordinary life any remarkable peculiarity, are yet susceptible enough to suggestion even to the point of believing implicitly a thing involuntarily suggested to them under the form of a simple interrogation. In this fashion, says M. Joire, a man subjected to the conditions of a simple examination, such as could be imposed by an examining magistrate or a commissary of police, did not hesitate to assert in writing that he had been present at the perpetration of crimes which were absolutely fictitious. Further, he recognized the criminal from among portraits which were shown to him.
The conclusion which the author draws from his experiments is that it is necessary to call the attention of the judiciary and of counsel to the possibility of such false witness. In case of doubt, counsel should not hesitate to demand an examination into the mental condition of the witnesses by a physician specially competent to investigate the question of suggestion.

In Anglo-Saxon courts "leading questions" are not supposed to be admissible. The wisdom of this course receives a special indorsement from the foregoing considerations. The objection to them is based rather on their possible use as "pointers" to direct an intentionally partisan witness to the desired answer; but their dangerousness as a means to mislead by "suggestion" a perfectly well-intentioned witness is equally obvious. The Latin countries might with advantage initiate a judicial reform by the adoption of this principle.

CONSUMPTION IN CALIFORNIA AND THE STATE BOARD OF HEALTH.

A dispatch to the New York Times announces that the State board of health of California has resolved to "consider the propriety of quarantining against human beings and domestic animals with tuberculosis entering the State." There can be no harm in the board's considering the matter, but we trust it will do nothing rash. Less quarantining should be done rather than more.

THE NURSING SERVICE IN THE PHILIPPINES.

It was stated not long ago that there was a disposition on the part of General Otis to rate the need of nurses in the Philippines lower than it was estimated by Colonel Woodhull, the chief surgeon in Manila. This we deprecated at the time, and we are now glad to learn by the Army and Navy Journal for September 9th that the surgeon-general is waiting for a dispatch on the subject from Colonel Woodhull, and that efforts are being made to recruit adequate hospital corps for the regiments now in the Philippines and the new regiments to be sent there.

"PERVERSE ACTION" OF THE VELUM PALATI.

The vocal bands, it seems, are not the only parts open to the reproach of "perverse action," for Sänger, of Magdeburg (Wiener klinische Rundschau, August 6th), applies it to the velum of the palate in a case in which a nasal twang was produced by abnormal elevation of that structure in the articulation of certain consonant sounds. He says that he has seen three such cases.

THE DANGER OF STEAM CAUTERIZATION OF THE UTERUS.

That cauterization of the uterus by means of steam, the so-called atmoaeasis, is not devoid of danger is shown by a case reported by von Guérard, of Düsseldorf (Centralblatt für Gynäkologie, September 2d). After its performance the woman was confined to bed for five or six weeks, and this was followed by such persistent pain in the back that she submitted to hystereotomy. There was absolute atresia of the cervical canal, with extraordinary tenderness of all the genital organs, especially the uterus. Before being steamed she had had ventro-fixation of the uterus performed.

ERYsipelatous PNEUMONIA.

The old writers described such a disease, and its occasional occurrence seems to be substantiated by a case reported by Artaud and Barjou (Gazette des hôpitaux, 1898; No. 102: Centralblatt für innere Medizin, August 26, 1899). The patient, who was recovering from faecal erysipelas, was attacked in the spuita by dyspnoea disproportionate to the physical signs and with spasmodic cough. There were no pneunococci, but they contained the Streplococcus erysipelatos, as was shown by their producing typical erysipelas when inoculated on a rabbit's ear.

AURAL VARICES DUE TO PREGNANCY.

It seems difficult to account on mechanical grounds for the production of varices of the ear as a result of pregnancy. Warnecke (Archiv für Ohrenheilkunde, xliv; Deutsche Aerzte-Zeitung, September 1st) reports a case of varicose swellings of various sizes on the auricle and in the external auditory canal of a woman in the eighth month of her eleventh pregnancy. She stated that she had been affected in the same way in all her pregnancies, and that the swellings had always subsided at once on her delivery, although they had not wholly disappeared.

THE BACILLUS ICTEROIDES CONTROVERSY.

Dr. Sanarelli's criticisms of the work done by Surgeon Walter Reed and Acting Assistant Surgeon James Carroll, of the army, have led those gentlemen to reply in the Medical News for September. They show that Sanarelli's suggestion that they had accidentally "mixed" the Bacillus icteroides and the Bacillus cholerae suis was erroneous, and they appear to show that some of his statements concerning hog cholera are not true. Finally, they declare that they are more than ever inclined to look upon Sanarelli's bacillus as a variety of the hog-cholera germ and as a "secondary invader" in cases of yellow fever.

THE BULLETIN OF THE JOHNS HOPKINS HOSPITAL.

A double number of this excellent publication, for August and September, is largely devoted to historical and biographical matters. One of the most interesting articles, by Dr. Charles C. Bombaugh, is entitled Female Poisoners, Ancient and Modern. More of this sort of writing would not, in our opinion, be out of place in our medical periodicals.
Surgeon Daniel M. Stimson, resigned; that Dr. R. M. Daly has been appointed assistant surgeon to the Sixty-ninth Regiment; and that Surgeon Frederick J. J. Wood, of the Forty-seventh Regiment, has been chosen to represent New York State at the meeting of the Association of Military Surgeons to be held in Kansas City on September 27th.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending September 16, 1899:

Change of Address.—Dr. G. Kremer, to No. 343 East Eighty-fourth Street, New York.

Marine-Hospital Service Health Reports.—The following cases of small-pox, yellow fever, cholera, and plague were reported to the surgeon-general during the week ending September 15, 1899:

**Small-pox—United States.**
- Jacksonville, Fla., Sept. 2, 1 case.
- Fall River, Mass., Sept. 2-9, 1 case.
- Cincinnati, Ohio, Aug. 25-Sept. 1, 6 cases.
- Cleveland, Ohio, Sept. 1-8, 4 cases, 1 death.
- Philadelphia, Pa., Sept. 2, 1 case.
- San Antonio, Texas, Aug. 31, 1 case.
- Texas, sixteen places, Aug. 3-Sept. 2, 76 cases, 4 deaths.
- Portsmouth, Va., Sept. 9, 1 case.

**Small-pox—Foreign.**
- Antwerp, Belgium, Aug. 26, 3 cases.
- Rio de Janeiro, Brazil, July 28, 54 cases, 34 deaths.
- Casilda, Cuba, Aug. 1-8, 2 cases.
- Athens, Greece, Aug. 26-28, 11 cases, 2 deaths.
- Bombay, India, Aug. 15, 11 cases.
- Chihuahua, Mexico, Sept. 4, 4 cases.
- Mexico, Mexico, Aug. 20-27, 4 cases, 2 deaths.
- Mexico, Mexico, Aug. 19-28, 5 cases, 2 deaths.
- Taxpan, Mexico, July 4, 2 cases.
- Moscow, Russia, Aug. 12-19, 1 case, 1 death.
- Odessa, Russia, Aug. 19-26, 1 case.
- Warsaw, Russia, Aug. 12-19, 3 cases.
- Valencia, Spain, Aug. 22-29, 4 cases, 5 deaths.
- Erzeroun, Turkey, Aug. 5-12, 2 cases.
- Smyrna, Turkey, Aug. 13-20, 1 death.

**Yellow Fever—United States.**
- Key West, Fla., Sept. 9-12, 92 cases, 3 deaths.
- Port Tampa City, Fla., Sept. 11, 1 death.
- New Orleans, La., From outbreak to Sept. 11, 7 cases, 2 deaths.
- Jackson, Miss., Sept. 10, 1 case.
- Mississippi City, Miss., Sept. 10, 1 case.

National University of Washington, D. C.—We learn that Dr. J. Carlisle De Vries has been appointed professor of pathology at the National University, Washington, D. C.

Naval Intelligence.—Official List of Changes in the Medical Corps of the United States Navy for the Two Weeks ending September 16, 1899:

- BOGERT, E. S., Passed Assistant Surgeon. Detached from the marine recruiting rendezvous, New York, and ordered home to await orders.
- ELLIOTT, M. S., Assistant Surgeon. Detached from the marine recruiting rendezvous, Chicago, and ordered to the marine recruiting rendezvous, New York.
- LOVERING, P. A., Surgeon. Ordered to duty at the marine recruiting rendezvous, Buffalo.
- MOORE, J. M., Passed Assistant Surgeon. Detached from the Vermont and ordered to the marine recruiting rendezvous, Chicago.
- TRYON, J. R., Medical Director. Detached from duty as general inspector of naval hospitals and ordered home to await orders.
- VON WEDEKIND, L. L., Passed Assistant Surgeon. Granted sick leave for three months when discharged from the Naval Hospital, Mare Island, California.

Marine-Hospital Service.—Official List of Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the United States Marine-Hospital Service for the Twenty-one Days ending September 14, 1899:

- WHITE, J. H., Surgeon. Directed to proceed to National Soldiers' Home, Virginia, for special temporary duty.
- MAGRUDER, G. M., Surgeon. To proceed to Port Tampa, Florida, for special temporary duty.
- WERTENBAKER, C. P., Passed Assistant Surgeon. Granted leave of absence for fourteen days on account of sickness.
- SMITH, A. C., Passed Assistant Surgeon. To proceed to Tortugas Quarrantine for special temporary duty.
- GARDNER, CHARLES H., Passed Assistant Surgeon. Granted leave of absence for one day.
- WICKES, H. W., Passed Assistant Surgeon. Leave of absence extended four days.
FRICKS, L. D., Assistant Surgeon. To proceed to Key West, Florida, for special temporary duty.

CORPET, G. M., Assistant Surgeon. Relieved from duty at Egmont Key Detention Camp, Florida, and granted leave of absence for thirty days on account of sickness.

KING, WALTER W., Assistant Surgeon. Relieved from duty at Beedy Island Quarantine and directed to proceed to New Orleans and report to the commanding officer for duty and assignment to quarters.

THORNHURST, F. J., Assistant Surgeon. Relieved from duty at Baltimore and directed to proceed to the Immigration Depot, New York, and report to the commanding officer for duty.

TROTTER, F. E., Assistant Surgeon. Relieved from duty at Immigration Depot, New York, and directed to proceed to Mulkey Detention Camp, Florida, and assume command.

BEAN, J. C., Acting Assistant Surgeon. Granted leave of absence for one day.

BROWN, B. J., Acting Assistant Surgeon. Granted leave of absence for three days.

DUFFY, FRANCIS, Acting Assistant Surgeon. Granted leave of absence for two days.

GOLDSBOROUGH, B. W. Acting Assistant Surgeon. Granted leave of absence for one day.

SMITH, A. W., Acting Assistant Surgeon. Relieved from duty at Cape Charles Quarantine and directed to rejoin station at Baltimore.

PECK, F. H., Hospital Steward. Relieved from duty at Hampton, Virginia, and directed to proceed to Mulkey Key Detention Camp, Florida, for special temporary duty.

OLESEN, E. T., Hospital Steward. To proceed to Tortugas Quarantine for special temporary duty.

CARTER, H. R., Surgeon. To proceed to Key West, Florida, for special temporary duty, and from Key West, Florida, to New Orleans, Louisiana, to assume charge of service matters.

MAGRUDER, G. M., Surgeon. To proceed to New Orleans for special temporary duty.

PERRY, T. B., Passed Assistant Surgeon. Relieved from duty at San Francisco and directed to proceed to Stapleton, New York, and report to the commanding officer for duty and assignment to quarters.

EAGER, J. M., Passed Assistant Surgeon. To proceed to Saginaw, Michigan, as inspector.

ROSEN AU, M. J., Passed Assistant Surgeon. Detailed as temporary quarantine officer at Havana, Cuba.

NYDEKKER, J. A., Passed Assistant Surgeon. Relieved from duty at Marine Hospital, New Orleans, and directed to report to Surgeon MAGRUDER for special temporary duty.

BLUE, RUPERT, Passed Assistant Surgeon. Granted leave of absence for one month and eight days from October 6, 1899.

MCMULLEN, J., Assistant Surgeon. To proceed to Memphis for special temporary duty.

VON EZDORF, R. H., Assistant Surgeon. Relieved from duty at Hampton, Virginia, and directed to rejoin station at New Orleans.

ADAMS, F. B., Acting Assistant Surgeon. Granted leave of absence for ten days.

**Appointment.**

AGNELLY, EDWARD J., of New York, to be junior hospital steward.

**Board Convened.**

Board convened to meet at New York, October 4, 1899, for the examination of candidates for appointment as assistant surgeon in the service and officers for promotion. Detail for the board: AUSTIN, H. W., Surgeon, chairman; STONE, G. W., Surgeon; BANKS, C. E., Surgeon, recorder.

**Society Meetings for the Coming Week:**

**MONDAY, September 25th:** Medical Society of the County of New York; Lawrence, Massachusetts, Medical Club (private); Cambridge, Massachusetts, Society for Medical Improvement; Baltimore Medical Association.

**TUESDAY, September 26th:** New York Dermatological Society (private); Metropolitan Medical Society, New York (private); Buffalo Academy of Medicine (Section in Obstetrics and Gynecology); Rome, New York, Medical Society; Medical Society of the County of Lewis, New York (quarterly); Boston Society of Medical Sciences (private); Richmond, Virginia, Academy of Medicine and Surgery.

**WEDNESDAY, September 27th:** New York Academy of Medicine (Section in Laryngology and Rhinology); New York Pathological Society; American Microsopical Society of the City of New York; Auburn, New York, City Medical Association; Berkshire, Massachusetts, District Medical Society (Pittsfield); Philadelphia County Medical Society.

**THURSDAY, September 28th:** New York Academy of Medicine (Section in Obstetrics and Gynecology); New York Orthopedic Society; Brooklyn Pathological Society; Brooklyn Society for Neurology; Roxbury, Massachusetts, Society for Medical Improvement (private); Pathological Society of Philadelphia (conversational).

**Births, Marriages, and Deaths.**

**Married.**

HOOVER—RYDER.—In Greene, Rhode Island, on Friday, September 8th, Dr. John H. Hoover and Mrs. Harriet Ryder.

MARTIN—SOUCHON.—In New Orleans, on Thursday, September 14th, Mr. Henry Martin and Miss Ophelia Souchain, daughter of Dr. Eugene Souchain.

MCDONALD—MCINTYRE.—In Williamsport, Pennsylvania, on Thursday, September 14th, Dr. Hugh McIntyre, of Buffalo, and Miss Frances McDowall.

SANTRY—MULLEN.—In Little Falls, New York, on Monday, September 18th, Dr. Augustus Bernhard Santry and Miss Margaret Frances Mullen.

WEBSTER—JONES.—In Brockville, Ontario, on Tuesday, August 29th, Dr. Robert E. Webster and Miss Irene Jones.

**Died.**

CLEMENS.—In East Arlington, Vermont, on Saturday, September 16th, Dr. A. B. Clement, in the thirty-first year of his age.

ROGERS.—In North Creek, New York, on Thursday, September 14th, Dr. Samuel H. Rogers.

SCHENCK.—In Brooklyn, on Tuesday, August 15th, Dr. Tunis Schenck, in the fifty-eighth year of his age.
The loss of time caused by such injury, together with the direct result of such improper treatment.

And in cases where the injury is shown to be permanent, the jury may consider its effect upon the plaintiff's capacity to earn money in the future, and also consider future pain and suffering, both physical and mental.

Exemplary Damages.—Whenever the unprofessional treatment upon which the suit is based is attended with fraud, malice, or gross negligence, and such fact is shown to the jury by the evidence, they may, in assessing the plaintiff's damages, consider not only the actual expense inflicted upon him, together with the amount proper to compensate him for physical and mental anguish, but may go still further and inflict damages upon the defendant for his intentionally vicious or grossly improper act. Such damages are exemplary or punitive, and are allowable upon the theory that they will act as a punishment to the wrongdoer, and thereby deter others from committing like flagrant acts.

While the foregoing general treatment of damages as involved in the scope of these articles is calculated to give the practitioner a comprehensive although rather superficial idea of the subject, it is thought that a more particular and less extended examination will be of greater value and more satisfactory to the reader. This effect is designed to be accomplished by examining particular cases, thus showing correctly the application of these governing rules.

Illustrations: Nominal Damages.—Nominal damages are proper and are the only damages that the jury will be permitted to assess either where no damages are shown by the evidence to have been sustained or where the injury sustained from the defendant's improper treatment can not be distinguished from the sickness or injury for which the plaintiff was treated.

In the case of Becker vs. Janinski, the plaintiff had a miscarriage. The evidence showed some improper treatment by the defendant; it also showed that the patient's general health was impaired. There was evidence introduced on behalf of the defendant to show the injurious effect of a miscarriage upon the general health, from which it was argued that the injury complained of to the plaintiff's health was the result of the miscarriage, for which the defendant was not to blame, and, at least, that it was impossible to say the injury was due solely to the alleged improper treatment. Upon this point the jury was instructed that "The defendant not being responsible for the miscarriage, he is not to be made liable for any of its consequences. If liable at all, he is liable only for the effects of his mal-treatment of the plaintiff. So that, should you find it impossible to distinguish between the consequences of the miscarriage and the consequences of the maltreatment—should you be unable to find upon the evidence that the plaintiff has suffered any injury distinctively due to maltreatment—you will award only nominal damages against the defendant."*

Illustrations: Compensatory Damages.—In this class of damages the jury are supposed to determine as accurately as possible the extent of the injury suffered by the plaintiff and give him damages which shall fairly compensate him for the loss and injury sustained. There are, however, so many elements to be considered in

determining damages in this kind of cases which can not be reduced to an accurate monetary basis that the verdicts of different juries will very materially differ in the same case.

This is very well illustrated in the case of Barns vs. Means. Here the plaintiff had sustained fractures of the tibia and fibula; that of the tibia was oblique and near the upper part of the lower third of the limb, while that of the fibula was nearly transverse, and was from three to four inches above the ankle joint. By reason of not applying extension and counter-extension at the proper time the bones were allowed to lap three quarters of an inch. This case was twice tried. The first jury assessed the damages at five hundred dollars. On motion of defendant the verdict was set aside, a new trial was had, and the damages were assessed by the new jury at one thousand dollars.

In the case of Wood vs. Clapp, a verdict of one thousand dollars was assessed where the evidence showed an improper and unsuccessful treatment of an arm which resulted in permanent disability.

In the case of Smothers vs. Hanks, both bones of the plaintiff's arm were fractured near the wrist. The evidence showed unskilful treatment. The arm, hand, and fingers were crooked and stiff—perhaps permanently so. The jury gave a verdict for two thousand dollars. This, on motion for a new trial, was reduced to twelve hundred dollars, probably by mutual consent of the parties.

In the case of Teft vs. Wilcox, the plaintiff, who had suffered from rheumatism and neuralgia in his shoulder, sustained a dislocation of the shoulder joint. From the improper treatment of this injury the shoulder became permanently disabled. His damages were assessed at two thousand nine hundred dollars.

It was held in the case of Kelsey vs. Hay that a verdict of four thousand five hundred dollars was not excessive where the plaintiff was crippled in both legs for life by the ignorance and mismanagement of his physician. The deformity complained of resulted from improper treatment of fractures in both legs, at what joints the report does not show.

In the case of Quinn vs. Higgins damages amounting to one thousand six hundred dollars were awarded for maltreatment of a fractured leg which resulted in a "false joint."

In the case of Williams vs. Poppleton the plaintiff had received an injury at the ankle, probably a dislocation and slight fracture. There was some evidence of improper treatment; the bones became diseased and the leg was amputated above the knee. The jury found a verdict of nine hundred dollars. Whether this verdict was intended as a compensation for the loss of the leg through improper treatment of the defendant, or whether it was for unnecessarily and improperly prolonging the plaintiff's sufferings in not performing the amputation for a considerable time after it should have been performed, does not appear. It was probably intended for the latter.

The jury awarded damages to the amount of two thousand and twenty-five dollars in the case of Howard vs. Grover, where the defendant performed two amputations upon the plaintiff's thigh, both of which were unsuccessful. The first amputation was at the proper place, but the bone was left protruding too far; the second was not shown to have been improperly performed, but was not performed at the right place. The court, in commenting upon the amount of this verdict, said: "The practice of surgery is indispensable to the community, and while damages should be paid for negligence and carelessness, surgeons should not be deterred from the pursuit of their profession by intemperate and extravagant verdicts. The compensation to surgeons in the country is small in comparison with what is paid in cities for similar services, and an error of judgment is visited with severe penalty, which takes from one a large share of the surplus earnings of a long life."

The court expressed the opinion that the jury must have been actuated "by some undue influence" in assessing the amount of damages; they expressed great reluctance, however, to interfering, and therefore stated that the verdict might stand if the plaintiff would remit five hundred dollars of the amount assessed.

It is perhaps proper to say that this case arose in Maine, and was tried in 1848.

For the improper treatment of an eye, from which loss of sight in that eye resulted, a Missouri jury gave a verdict of $362.75, evidently a compromise verdict.

For the failure of a physician to discover and repair a serious rupture of the perineum a Maine jury assessed damages at four hundred and fifty dollars. And for improper uterine treatment, whereby the neck of the womb became closed, entailing much suffering and considerable expense, a Wisconsin jury assessed damages at three hundred and fifty dollars.

Illustrations: Exemplary Damages.—Upon the question of exemplary damages, the case of Brooke vs. Clark is instructive. In this case the attending physician tied a ligature around the child's penis, instead of the umbilical cord, at his birth, whereby the glans of the penis came entirely off.

The facts may probably be best gathered from the evidence of the child's grandmother, which was as follows: "Dr. — was the attending physician. He was standing at the foot of the bed and received the child from its mother. Before receiving the child from beneath the bedclothes he tied one cord or ligature, and then removed the cover, tied the second ligature, and cut the umbilical cord, when the child was by Dr. — handed to the witness, who wrapped it in a blanket and sat by the stove trying to quiet it. When the first ligature was tied the child cried out like it was hurt, and continued to cry for about an hour. The doctor then took the child in his lap and examined it, and said the string had slipped off the navel cord. He asked for another string, which I gave him. I had given him one at his request before the child was born; both were common wrapping twine. Mrs. C. assisted Dr. —, and he tied a string on the navel cord and returned the child to me, and I washed and dressed it and cared for it until morning. The child had spells of crying through the night; all the dressing that was done next day was changing its diaper, and that was done by me.

Pith of Current Literature.

Splenectomy for Rupture.—Mr. George Heaton, F. R. C. S. (British Medical Journal, August 19th), in a paper on this subject read before the British Medical Association, thinks that from a study of seven cases recorded in the paper we are justified in arriving at the following conclusions: 1. That a marked leucocytosis follows removal of the spleen in these cases. The leucocytosis follows immediately after removal, and continues gradually to decline; but it exists in a less degree for six months or more. 2. That in the leucocytosis the various forms of leucocytes are increased in number in various proportions, and do not bear the same ratio to each other as in normal blood. 3. That the anaemia produced by the accident is very slowly recovered from after removal of the spleen. 4. That in a certain number of cases (three out of seven) the removal of the organ is followed at an interval of from ten days to three weeks by a train of symptoms characterized by pyrexia, wasting, extreme weakness, anaemia, frequent pulse, pallor, thirst, and headache, which last for a varying period and are slowly recovered from. 5. That the external lymphatic glands undergo enlargement and in some cases a marked hypertrophy.

The Ätiology of Night Terrors in Children.—Dr. E. Graham Little (British Medical Journal, August 19th), as the result of an examination of thirty cases, in a paper presented to the British Medical Association on this subject, draws the following deductions: 1. Night terrors are in the great majority of cases caused by disorders productive of moderate but prolonged dyspepsia. 2. A preponderating number of cases are found in rheumatic subjects with early heart disease. 3. A considerable proportion of cases are due to obstruction of the nasal cavities and faucets. 4. Digestive disturbances do not play the important part in causation that is often assigned to them. 5. The evidence for their causal connection with epilepsy or allied nerves is scanty. 6. The attacks occur in the subconsciously stage of early sleep and are confined to young children under puberty.

Uterine Tuberculosis.—Vassmer (Archiv für Gynaekologie, Band Ivii, Heft 2, 1899; University Medical Magazine, September) believes that tuberculosis of the uterus is of considerable clinical importance, since it is observed quite frequently. The six cases he reports were found at Runge’s clinic within a space of ten months. From a study of these cases and those to be

* Howell vs. Goodrich, 69 Ill., 556.
found in the literature he classifies the pathological anatomy and the clinical characteristics of the disease. All of the forms of tuberculosis which are described as occurring in the cervix (disseminated miliary, endo-
metritis caseosa, and ulcerative endometritis), except the tuberculous new growths, were observed in the six cases. In most instances there was an associated tubercu-
losis of the annexa, there being isolated endometrial tuberculosis in only one case. Anomorrhea was a character-
sitic symptom in all cases where the endometrium was found extensively diseased, and amenorrhagia and menorrhagia when the disease was not advanced. In four cases the diagnosis was made by the micro-
scopical examination of tissue removed by the curette. In the cases of isolated and advanced tuberculosis reported many curettements did not suffice to cure the disease, but when mild, there was always a marked improvement. The possibility of there developing a miliary tubercu-
losis after conception, abortion, or labor, also the pos-
sibility of infection being carried from the placenta (which can no longer be doubted), determines the treat-
ment to be a radical one (hysterectomy) when the pa-

tient is in the period of sexual activity. The presence of pregnancy in a tuberculous uterus must always be 
looked upon as a very serious complication.

Extrarenal Capsule in Eye Diseases.—Dr. W. H. Bates (Archives of Ophthalmology, May), who first called attention to this subject in the New York Medi-
cal Journal for May 16, 1896, says that the aqueous ex-
tract of the suprarenal capsule is a powerful astringent.
When a drop of the aqueous solution is instilled into an inflamed eye, the conjunctiva of the globe and lids is whitened in an average case in one minute. The effect is very decided. In mild cases the whitening may be more than normal. In severe cases of congestion or in-
flammation the eye is whitened to an appreciable degree. No case has been found in which the extract did not act. The astringent effect is increased by repeated instil-
lations or by the use of a stronger solution. The cause of the whiteness has no effect on the result. An eye irritated by a foreign body on the cornea can be promptly whitened by the extract, as well as eyes inflamed from local infection or as a complication of gen-
eral disease. The effect is usually temporary. In most cases after half an hour the eye looks as it did before the extract was used. The extract is not irritating. It generally produces a cooling sensation in the eye. It has no effect on the nervous system directly. The pupil is not constricted or dilated by it, and the accommoda-
tion is never affected. The extract has no anesthetic property, and when pain is relieved by its use the bene-
fit comes from the lessened congestion produced by the extract. A tolerance is never acquired; one patient used the extract daily for six months, and the eye was whitened temporarily by it at the end of that time as in the beginning. No secondary effect was observed; inflamed eyes do not have an increase of congestion or pain after the effect of the extract has worn off. The suprarenal extract does not cause desquamation of the corneal epithelium in normal or inflamed eyes in his experience. Ten experiments were undertaken to deter-
mine this with normal eyes in which the suprarenal ex-
tract was instilled at short intervals for three hours and no desquamation followed. Five cases with purul-
ent keratitis were subjected to the action of the ex-
tract at frequent intervals for one hour without desqu-
amation. A thirty-per-cent. solution did not cause desquamation of the corneal epithelium in a normal eye after one hour's use. The hypodermic administration of the extract is very painful.

It was observed that the instillation of the supra-
renal extract into the eye had an effect on the general circulation as well. Therefore it was necessary to learn that pathological conditions contraindicated the use of the extract. An extensive series of observations showed that the extract might be instilled with safety in the eye in advanced stages of organic heart disease, pneumonia, nephritis, and in other serious conditions. Incidentally it was discovered to be an ideal heart tonic. The author was the first to publish its use as a heart stimulant in various forms of heart disease (Medical Record, Octo-
ber 8, 1898).

The aqueous solution is prepared as follows: Five grains of the dried and pulverized gland of the sheep are mixed with one drachm of water. The mixture stands five minutes and is then filtered. The filtrate contains about one per cent. of the extract. A solution of thirty-
three per cent. can be obtained. It may be sterilized by heat or preserved at a low temperature. It can not be mixed with antisepsics, preservatives, or with any other substances without impairing its astringent prop-
erty in the eye. It is best to prepare it freshly when needed. The dried and pulverized suprarenal capsule keeps indefinitely. It can be obtained from Armour & Co., Chicago, Illinois.

The solution when properly prepared is of a light brown color. One drop in a normal eye should whiten the caruncle more than normal in less than one minute.

The extract is very soluble in water, insoluble in strong alcohol, chloroform, and ether. When dried it is of a light yellow color.

Oliver and Schäfer (Journal of Physiology, 1895) find that the extract increases the tone of all muscular tissue by direct action. When the suprarenal capsule is removed, the heart and muscular system generally are weakened, with great want of tone in the vascular sys-
tem. The author next records cases treated with the ex-
tract. Acute conjunctivitis was cured by its use, but in chronic conjunctivitis the relief was only temporary. Purulent conjunctivitis and trachoma were benefited, but not cured. Keratitis, iritis, and dacrocystitis needed other remedies in addition. The drug, says the au-
uthor, is only astringent and not antiseptic. It has no effect on diseased bone.

The astringent property of the extract is invaluable, distinguishing between strictures of the nasal duct, due to swelling or inflammation of its mucous membrane, and impervious organic strictures. In the former, the extract finds it way into the nose when syringed into the sac through the punctum, and the stricture can be cured by treatment without operation; in the latter, an impervious stricture is usually present when the extract fails to find its way into the nose after repeated trials.

Short operations on normal eyes are usually done painlessly with cocaine alone. But in nervous people, inflamed eyes, eyes congested after recent operations, prolonged operations, and in bloody operations cocaine does not usually secure complete anesthesia. In these cases the extract is of great service.

In a number of cases the absence of reaction after operations on the eye muscles when the extract was used was noted.

For cataract extraction, cocaine is usually perfectly satisfactory in performing a painless operation, but ex-
ceptions occur. In a recent case after the section was
completed, the patient complained that the eye was tender. It was impossible to touch the cornea without pain. Cocaine, four per cent., was instilled frequently for fifteen minutes without producing anesthesia. The patient complained that the drops hurt. The patient had a bad heart and ether was objectionable. A few drops of the suprarenal extract were instilled. The patient's nerve seemed to return. Cocaine now produced anesthesia, and the operation was finished in a few minutes. The author feels certain that he could not have extracted the lens and obtained good vision in this case without the extract.

The extract is valuable in the inflammatory cases of glaucoma in which ether is usually necessary to secure anesthesia for iridectomy. The suprarenal extract lessens the congestion so that cocaine can act. In one case cocaine was instilled for half an hour without producing anesthesia. A drop of suprarenal extract whitened the eye. The cocaine anesthetized the eye immediately, and a painless iridectomy was completed in five minutes from the time the extract was instilled.

Among general uses of the extract, Mullen (American Journal of Ophthalmology, August, 1898) has reported painless and bloodless major operations on the nasal septum with cocaine and the extract. The ossicles and drum membrane have been removed without pain or hemorrhage with the use of the extract (and cocaine). Swain (New York Medical Journal, December 24, 1898) finds that it reduces enlarged tonsils, besides whitening the nasal mucous membrane. Urethral strictures have been opened in the same manner as laryngeal strictures were benefited. Its power of reducing granulations in the eye and hastening repair has been observed also in the treatment of ulcers of the leg.

Dr. A. G. Aldrich (Medical Standard, September) indorses Dr. Bates's experience. He thus sums up his conclusions: 1. The extract of suprarenal capsule is one of the most powerful of vaso-constrictors, and is, in addition thereto, an erectile tissue contractor. 2. As such it allows a deeper and more perfect anesthetic action from the local use of cocaine enabling the surgeon to have highly anesthetized surfaces and tissues for operation. 3. The ischemia from such action is so profound as to act as a prolonged hemostatic, giving thereby a clear field for operation, and preventing secondary hemorrhage. 4. Its action can be depended upon in every case. It is in no way deleterious to tissues operated upon, nor does it interfere with aseptic healing.

Convulsions in Infancy.—Dr. A. M. Gossage and Dr. J. A. Coutts (British Medical Journal, August 1st to 19th), in an exhaustive paper on this subject read before the British Medical Association, arrive at the following conclusions: 1. The frequency of convulsions in infants has been vastly overrated. 2. The immediate danger of a fit has been overrated, while the danger as regards future neurotic manifestations has been underestimated. 3. The predisposing causes are of much more importance than the exciting causes; the slighter exciting causes will not produce convulsions except in predisposed infants.

Interscapulo-thoracic Amputation.—Mr. Mayo Robson, F. R. C. S. (Lancet, July 29th), records two cases of his own of this operation in both of which there was little or no shock, and rapid recovery ensued, the patient being out of bed in the second week with the wound healed by first intention. Mr. Robson points out that the elaborate details for incision and technique given by Berger and others are practically useless, inasmuch as the flaps must necessarily be taken from wherever unaffected skin is available. Mr. Robson's operations were undertaken in the first case for extensive recurrent sarcoma of the axilla, and in the second case for extensive tuberculous disease of the shoulder joint, scapula, and elbow, with osteomyelitis of the humerus. The flaps were taken in one case from the anterior, in the other from the posterior surface of the upper arm. For preventing loss of blood the limb to be removed was Esmarched and a tourniquet was applied at the middle of the arm so as to utilize all the blood in the arm to be removed, this being supplemented in the first case by exposure of the subclavian artery and vein and clamping them with large pressure forceps, and in the second case by pressure on these vessels above the clavicle by means of a well-padded forceps handle. During the course of the operation the vessels were caught in pressure forceps immediately on division and subsequently ligatured, the loss of blood in each case being trifling. As a pocket is necessarily left when the wound is closed the author found an advantage in draining it by means of a stab wound at the most dependent part, the tube being removed in thirty-six hours. The subsequent deformity, says Mr. Robson, is so great that apart from any risk in the operation itself it can only be justifiable where all other means of relief have been exhausted.

The operations in the two cases are described as follows:

In Case I, owing to the condition of the axilla and front of the deltoid, no regular operation could be done. The subclavian vessels were exposed, clamped, and then divided along with the brachial plexus above the clavicle and beyond the growth. The outer half of the clavicle, together with the arm and the scapula, were then removed, a flap of skin having first been dissected up from over the back of the deltoid and upper arm. There was very little loss of blood, as the vessels were seized immediately they were divided. The removal of the scapula was facilitated by an assistant rotating the arm and forcing it forward and outward. The wound was stitched up closely and a drainage tube was introduced through a stab wound. There was practically no shock from the operation, and the patient was up on the ninth day, the wound having healed by first intention.

In Case II ether was given and with the patient lying on his left side an incision was made, the flap being taken from the front of the upper arm. Bleeding was checked by pressure on the subclavian above the clavicle with forceps padded at the end with lint. The flap was first raised, taking only skin and superficial fascia, and the muscles were then divided down to the clavicle, which was divided by bone forceps. The axillary vessels were now clamped and divided. The other vessels were taken up with pressure forceps as they were cut and very little blood was lost. Then by rotating the arm the scapula was forced forward and outward, the muscles attaching it to the trunk were divided, and the limb was removed. The vessels were then tied and pressure was removed from the subclavian. One or two large glands were removed from the axilla. The wound, which had been contaminated with pus from the diseased part, was thoroughly washed with perchloride lotion. A drainage tube was inserted through the flap by a stab puncture in the postero-inferior part of the
The wound. The wound was then closed and a dressing was applied. The flap covered the wound readily without tension. The after-course was quite uneventful and the wound healed by first intention. The patient was up on the eleventh day. When seen four months later he had regained his old weight and color and was well in every respect.

Beri-Beri.—Dr. Albert S. Ashmead, late foreign medical director, Tokyo hospital, Japan (University Medical Magazine, September), says that in a recent issue of the Sun it was stated that beri-beri, a disease of the wet season of India, had broken out among the Filipinos of Cavite, and that there were two deaths a day from it. Dr. Ashmead, who says that he has treated thousands of cases of this disease, calls attention to a suggestion from himself published in the University Medical Magazine for May, 1896.

Dr. Ashmead then said that “Dr. Carrean, of Guadeloupe (Contribution au traitement de la lepre, Pointe-a-Pitre, Guadeloupe, 1892), mentions the case of a Brazilian leper bitten by a rattlesnake. The man succumbed after twenty-four hours. It was observed when he was dead that all his leprous were enfeebled. Dr. Carrean, attributing this effect to the methemoglobinemia produced by the venom, tried to imitate the intoxication in the case of a very sick leper. He gave him enormous doses of chlorate of potassium, a salt which increases rapidly the quantity of hemoglobin of the blood, and may cause death by this same action. The patient swallowed forty-five grammes of this remedy in three doses, the highest being twenty grammes, in sixty hours. He presented the most pronounced symptoms of intoxication; his blood showed the spectroscopic bands of hemoglobin and methemoglobin. During some days he hovered between life and death. He recovered, however, from the shock, and felt a very distinct improvement in all the cutaneous surface attacked; the leonine face smoothed down, the skin, which had lost all elasticity, could again form folds. The treatment continued eight days.”

Dr. Ashmead suggested that a remedy which had such an effect—that is, to increase so rapidly the hemoglobin of the blood—might also be applied to the treatment of beri-beri, a disease whose principal characteristic was the diminution of the hemoglobin.

The author adds a few words generally about this aetiologically mysterious disease. “Beri-beri” means “goat’s gait” or “sheep’s run,” and has reference to the dropping of the toes, or pes equinus, and the labored lifting of the leg and thrusting of it forward. These symptoms, he says, are due to hemoglobinemia paralysis of the peripheral nerves, arising, in his opinion, from carbolic poisoning.

In Japan, and the Far East generally, beri-beri is caused by the fumes of charcoal, the fuel of the stoves. In the wet season these fumes are held down by the moisture of the air. In the dry season there is no beri-beri at all, the dry northwest winds dissipating the gases. The author has examined a number of beri-beri ships in the harbor of New York, mostly from Dutch India and the Philippines, and in every instance the cargo was such as would produce an emanation of carbonic gases—graphite, pure carbon, from Colombo, Ceylon; burned coffee, from Java; fermenting third-grade sugar and crude sugar without fermentation—that is, undetected fermentation—from Iloilo, and wet grain and hemp cargoes. He has never seen or heard of such an afflicted ship that was not carrying a carbon-producing cargo. As to the theory propounded by the Dutch East Indian doctors, that white rice (so largely eaten by all East Asians), being infected with a micro-organism of beri-beri, is the means of propagation of the disease, he says that rice is always eaten well cooked (as the bread of the East), and that therefore a micro-organism, if it existed in white rice, would be destroyed, and consequently could not have anything to do with beri-beri. He adds that for many years Japanese rice has been sold in all American department stores, and, he need hardly say, is imported uncooked. If it contained the “microbe of beri-beri,” that microbe would have been rampant among us for many years. We have never had beri-beri in New York except on ships which had contracted the disease during their voyage.

Eye Diseases and Nervous Breakdown.—Dr. George M. Gould (Journal of the American Medical Association, September 9th) says that there are very many thousands of patients systematically treated for functional diseases of the body that are due to diseases of the eyes.

Out of perhaps a hundred classes the author chooses one small group of cases illustrative of the general thesis. This group is composed of “nervous” hysterical patients, usually women, neurasthenies, whom, when we do not know what is the matter with them, and when we can relieve them by no other means, we call “nervous breakdowns,” and order for them the rest cure. Modern medical practice is made up in too large degree of this sort of work in the dark—with patients whose diseases we may name but can not thoroughly diagnosticate, and the treatment of which we order with a sickening feeling in our own hearts that we are blind and ignorant of any clear reason for our doing. In no class of cases is there such great reason to look after the eyes as in this class of hysteries and neurasthenies, which by a morbid philology we allow to be called “nervous.” Dr. Gould is told that Dr. Spivak, of Denver, has advanced the theory that hyperchlorhydria and other functional gastric troubles are the principal affections relieved by the rest cure. To this he would add that nothing is more certain in his mind than that such functional gastric derangements are frequently the direct result of eye strain.

The author next records three cases in all of which asymmetrical astigmatism was found in conjunction with the symptoms of nervous breakdown, functional digestive troubles, headaches, anaemia, and other nervous phenomena. Proper glasses corrected the troubles, but for some reason glasses were discarded as the troubles began to disappear. Then followed a return of the symptoms, the prescription of the rest cure, with relief consequent on enforced idleness, dissipated, however, the moment the rest cure was abandoned. The only remedy in such cases, according to Dr. Gould, is the adoption of proper glasses and their continued use. The author concludes: “I should be sorry to be misunderstood. I by no means say or believe that in every case, or that in the majority of cases requiring the rest cure, the origin or chief factor of the disease is eye strain. I do not say or believe that the rest cure is unnecessary even in cases of reflex ocular neuritis. What I do believe and wish to emphasize is: 1. It is positively criminal negligence to ignore eye strain in any case requiring the rest-cure treatment. 2. It is not enough to know that the oculist has examined the eyes, especially
if it has been done without a mydriatic. 3. To mydriaticize a pair of eyes for a month or two would often do more good, would certainly be more logical, would be an infinitely better means of differential diagnosis in obscure nerve trouble and functional nutritional diseases than to put the patient's body to bed for the same time.

Proceedings of Societies.

SOCIETY OF THE ALUMNI OF THE CITY (CHARITY) HOSPITAL.

Meeting of May 10, 1889.

The President, Dr. William L. Stowell, in the Chair.

(The conclusion from page 326.)

The Early Recognition of Kidney Disease.—Dr. T. H. Rockwell read a paper on this subject. (See page 446.)

Dr. Barker said that he had been particularly interested in Dr. Rockwell's paper. It had seemed to him that in what Dr. Rockwell had said about the microscopical examination he had perhaps laid too much stress on the finding of casts and not enough on the other appearances. It should be remembered that while every inflammation of the kidney was (from the strict pathological standpoint) a diffuse nephritis, there were many cases in which the inflammation was so largely confined to the connective-tissue stroma that the exudative process played a very unimportant part, and that, therefore, casts were extremely rare or altogether absent. It was quite possible for these cases of interstitial nephritis to reach an advanced stage without any casts being discoverable even with careful search. In such urine, however, there would be found, as a rule, characteristic renal epithelia which were of importance, and familiarity with them was of great assistance in making a diagnosis. Unfortunately, these bodies were too frequently looked upon as leucocytes, which they did resemble unless examined with care. Though they were irregularly cuboidal while in situ in the tubules of the kidney, they became quite spherical when free in the urine and relieved of the pressure of their fellow cells. They were, however, on the average, about a third larger than the pus corpuscles, and as a rule with a single nucleus. Such epithelium were not found in normal urine, as were the squamous epithelia of the lower parts of the urinary tract, but were shed when the underlying connective tissue became inflamed, as it did in interstitial nephritis. The only epithelium found in urine which really resembled the renal epithelium were those from an inflamed prostate or Bartholinian gland and those from the ureters. All of these, however, were somewhat larger on the average than the kidney cells, and, taken in conjunction with the other chemical and microscopical features of the urine and with the clinical history, the diagnosis was not hard.

The speaker presented a specimen of urine from a case that he had seen that afternoon. The patient was a woman twenty-eight years of age, who complained that for several months she had been feeling badly and had suffered from headache almost daily. She was anaemic and slightly puffy under the eyes. The urine showed fully one half per cent. albumin (Esbach), and under the microscope were to be seen pus corpuscles and convoluted tubule epithelia containing fat globules. In four slides examined (without mechanical stage) no casts had been found—nor had they seemed necessary to make a positive diagnosis of chronic interstitial nephritis. The speaker thought, too, that the significance of connective tissue in the urine had not received the attention it deserved. In some cases of chronic interstitial nephritis it was at times possible to detect small shreds of connective tissue where casts could not be found at all or only with great difficulty. Such shreds might not help much with the diagnosis, but they did indicate the severity of the lesion. It seemed odd that the books had not given more attention to it. One heard of connective tissue in the sputum, but in the urine, where it was as frequently found, it was rarely mentioned. In certain conditions of the urinary tract it was possible to find quite large pieces. It was his opinion that even insurance men failed to realize what could be accomplished by careful microscopic examination of urine, and were inclined to make their progress along the line of chemical work, such as the differentiating of the various albumins, rather than in trying to understand more fully the various microscopical appearances. There was room in this direction for some good work.

Dr. Henry II. Schroeder said they were fortunate in having Dr. Rockwell present to speak upon this subject. One with such extended experience and in his position had even a better chance for studying the first signs of kidney disease than the general practitioner, because the first symptoms, as a rule, for which the patient sought advice, were changes in the condition of the heart and pulse; but preceding this there was almost invariably a change in the urine which, usually, was discovered accidentally. For the purpose of illustrating the frequency of albuminuria, Dr. Schroeder had looked over his records and found that about forty per cent. of his declinations and postponements had been for albuminuria pure and simple. No one supposed that all these cases were doomed to Bright's disease. As a matter of fact, he had since accepted many of them for insurance, the albuminuria having disappeared. The point was to find out whether the albuminuria was temporary or persistent; for the latter cases were in danger, and ought to be under the careful supervision of a physician who would insist upon regular habits, appropriate clothing, and abstinence from excesses in diet and stimulants, and who would see that all the functions were properly attended to, and that the patient refrained from overwork and violent exercise. He did not believe that albuminuria could ever be called physiological any more than we could designate the so-called uric-acid diathesis or the heart murmurs of anemia as such. Albuminuria, like many other abnormal conditions, might exist for more or less extended periods of time, and then disappear permanently, leaving the individual practically healthy; but while it lasted the patient could not strictly be said to be in a normal condition. At the same time, however, while observing every precaution, we should be guarded in our prognosis in these cases for we were not justified in fully establishing a diagnosis of Bright's disease until we perceived corroborative signs. A great many persons had albuminuria which recurred at certain times in the day—the so-called cyclical albuminuria; in others, the albuminuria might
be due to unusual exercise, dietetic influences, adolescence, or irritation of the lining membrane of the urinary tract. We could not distinguish the mild from the severe form by the amount of albumin, for in many instances of persistent albuminuria, even when the diagnosis of Bright's disease was positive, only a small quantity of albumin was present, whereas in a considerable number of cases of the transient form the amount was large. After the albuminuria had lasted a year or more, the prospect of its disappearance became very doubtful indeed. It was not uncommon to find an individual in whom albuminuria had persisted for years, without, apparently, any evil consequence. This fact could not be said to militate against the opinion that albuminuria was a condition of disease any more than the fact that patients with a mitral or even an aortic insufficiency, who may have lived for a long time without apparent inconvenience, were in a normal condition. He mentioned the case of a woman, at that time dying, who had contracted Bright's disease during pregnancy sixteen years previously. During this time her urine had been loaded with albumin and casts. Why, then, might not a persistent albuminuria, lasting for years, be the danger signal during all that time of a condition ready at any moment to develop into Bright's disease from some exciting cause? Albuminuria with urine of a persistent low specific gravity was a bad sign, and when albumin in large or small amount was associated with a diminished amount of urea, even though casts were absent, we might safely make a diagnosis of Bright's disease. The question of age was important, for if the patient was over forty years of age the albuminuria was a great deal more significant and less likely to disappear than in a younger person. When it occurred in the very corpulent it was apt to be permanent, even when the individual had not reached middle age. It was unnecessary to say that an albuminuric patient addicted to the use of alcohol was in more danger than others. Albuminuric patients did not stand intercurrent diseases at all well, and an acute trouble like pneumonia, or typhoid, or a surgical operation, or an accident often seemed to start up a condition that had long been lying dormant in the kidneys, and resulted fatally. The speaker had had the same experience as Dr. Rockwell with certificates, and attributed the case with which these statements were obtained to two things: First, the attending physician was anxious not to alarm his patient, and persuaded him that there was nothing wrong with his urine; this was very injudicious, for the patient ought to be impressed with the fact that his condition might lead to something more serious, and that he should keep himself under the care of his doctor. Second, some of these certificates were undoubtedly the result of faulty or careless methods of urinary analysis. The well-known heat and nitric-acid and Heller's tests were the most satisfactory. In analyzing the urine the main points to be observed were care, clean apparatus, and freeing of the urine from precipitates. Otherwise, small amounts of albumin escaped detection. It was not uncommon to see test tubes in the hands of a physician which were practically opaque. The tube that was employed for the sugar test should never be used for albumin. The outside of the tube should always be thoroughly dried before applying the heat, as even a small quantity of moisture left a deposit of salts sufficient to interfere with the transparency of the glass. It was the custom now to attempt to differentiate sero-albumin from nucleo-albumin, and we seemed fairly able to do so. As to whether nucleo-albumin was significant of serious disease or not, was still a matter of opinion. If we could always ascertain the exact source of this substance the question would be easier to solve, for it was manifest to all that it made a great deal of difference whether it came from the neighborhood of the prostate or from the pelvis of the kidney. The presence of epithelial cells was of little practical value, for, notwithstanding the statements in the text-books, no one could absolutely distinguish the epithelium of one part of the urinary tract from that of another. The speaker could believe that nucleoprotein was of comparatively little importance if he had not happened to have found renal casts associated with it in quite a number of instances. For this reason he was unwilling to accept these cases for insurance until a careful microscopic examination had convinced him that casts were absent, and even then, only when the nucleoprotein was small in quantity and the applicant was under middle age. If he had failed to emphasize the value of the microscope sufficiently, it was because he had tried to confine his remarks strictly to the symptoms of the incipient stage of Bright's. He thought that albuminuria was the chief evidence of the incipient stage, and that casts did not occur, as a rule, until later in the disease.

Dr. Laszynsky said he agreed with the previous speaker that physicians as a rule were careless in the examination of the urine. They looked at it, tested it for albumin hurriedly, saw if it was acid with a piece of litmus paper, and if they found no albumin they said it was normal. A great many never made a microscopic examination at all. He thought the paper one of the most instructive he had heard in a medical society for several years.

Dr. A. Rupp said he wished to say only a few words with reference to the lack of respect and exactitude that had been indulged in by the insurance specialists in accusing general practitioners of neglect and carelessness in the examination of urine. Individual instances of carelessness and neglect did not justify the condemnation of a class. Insurance examiners had the interests of their employers, the companies, to look after, and the practitioner was obliged to secure mental and physical welfare and comfort for his patient. These different ends in the two classes of practitioners did not always dovetail; but this did not justify insurance experts making sweeping assertions they did, to the disadvantage of the general practitioner. All general practitioners were not simpletons and incompetents.

Small amounts of albumin in the urine might not signify much in so far as the general health was concerned, or even possibly a happy and long life. The case of a man in the middle fifties was instanced as one in point. This man when about thirty years old had an attack of acute cystitis following a cold and distention of the bladder, and since that time his urine had shown traces of albumin. Six or seven years ago he was rejected by insurance experts. He is apparently as well to-day as he was six years ago. Six years ago he was advised by a urinary expert never to live in New York during the fall and winter, but to seek a warm climate. He had not taken the expert's advice, and apparently he was no worse off for not going South as advised. Dr. Rupp would not say that this slight amount of albumin in this man's urine was of no consequence, but he mentioned the case merely to demonstrate that slight albuminuria might coexist with apparent good health and mental vigor, and for many years, even after the middle period of life.
The President said that a number of years before he had examined large quantities of urine in connection with dispensary work, kept records of hundreds of cases, and considered that he had become reasonably expert at it. Out of large numbers of specimens examined many failed to bear out kidney disease, although the diagnosis of kidney disease had been made, and where he found the presence of albumin or of a few casts, it was not always wise to make a positive diagnosis. The casts simply helped out, because many specimens were sent in with a definite diagnosis of nephritis. On the other hand, he sometimes made a clinical diagnosis of Bright's disease well advanced, when the urine did not show it clearly. The subject seemed to have drifted largely to the early manifestations as seen in insurance work, but he had hoped some one would speak of the albuminuria in pregnancy, because it had sometimes been thought to be physiological, simply due to pressure. On the other hand, it might lead to a septic condition with renal complications. He referred to a case of pregnancy he attended about two months ago in which there was two per cent. of albumin, which appeared for the first time only a week before delivery, and disappeared absolutely two days after delivery, so that for a number of days the kidneys were overwhelmed with albumin, which disappeared as rapidly as any physiological act could take place, and had not recurred. It showed that the kidneys could excrete albumin in very large quantity without any probability of there being organic lesion in them or extensive degeneration.

**Book Notices.**

The Gross and Minute Anatomy of the Central Nervous System. By H. C. Gordinier, M. D., Professor of Physiology and of the Anatomy of the Nervous System in the Albany Medical College, etc. With Forty-eight Full-page Plates and Two Hundred and Thirteen Other Illustrations, many of which are printed in Colors, a Large Number being from Original Sources. Philadelphia: P. Blakiston's Son & Co., 1899. Pp. xxvi–17 to 559. [Price, $6.]

The author's object has been to prepare a text-book which shall meet the needs of medical students and at the same time be of service to clinicians in associating symptoms of nervous disease with anatomical facts. Beginning with the histology of the nervous system, there follow in systematic order chapters on the spinal cord, the medulla oblongata, the cerebellum, and the midbrain and third ventricle regions. Five chapters are devoted to the brain, its membranes and blood-vessels, and the three final chapters treat of cerebral localization, of the embryology of the central nervous system, and of the techniques of macroscopic and microscopic examination of the brain and spinal cord. In view of the constant accessions to our knowledge of the anatomy of the central nervous system, the task which the author set himself is of considerable proportions. He has, however, carried it through successfully. It can not be said that the book is beyond criticism; but that can be said of but few books, and of none which treats of a subject in which an attractive theory may be demolished between the time of writing and that of going to press. Dr. Gordinier's production is what it essays to be—a practical and reliable guide for students, for clinicians, and, to a certain extent, for original investigators in the field. It is hardly large enough to go into the discussion of most questions, and consequently it perforce contains statements which are based on insufficient authority and may some day have to be modified. For example, it is stated that a neuron is a distinct anatomical unit, which is by no means proved; and that Gower's tract is supposed to conduct cephalad impressions of heat and pain, a supposition for which the foundation is entirely inadequate. We note some imperfections in the use of terms, but they become very insignificant when compared with the really great merit of the work. For it represents much painstaking research and bears also the stamp of original investigation. It is unusually well written, and the illustrations, many of which are original, are well chosen. It is destined to take its place among the standard books of its class.

These lectures, which have already been published in full in the *Edinburgh Medical Journal*, were delivered by the grandson of the founder of the lectureship. They treat of an obscure and difficult subject. They are divided into the anatomy of visceral innervation, the physiology of visceral innervation, the pathology of visceral innervation, the disorders of visceral sensibility, and motion, body, and mind, and close with an appendix on the innervation of the intracranial vessels. The newer methods of staining nervous tissue have given us a very much keener insight into the finer anatomy of the sympathetic system than we had formerly, and have, to a certain extent, increased our knowledge of its physiology. The author has well summarized the advances made along these lines and has brought out as far as possible their application to the pathology of the sympathetic. He recognizes the present limitations of the subject, and is commendably conservative in the expression of his views. He is certainly justified in the opinion that further progress in technical methods will make this a fruitful field of investigation. The lectures are suggestive and interesting.

This is a very satisfactory dissertation on syphilitic diseases of the spinal cord. The author presents fully and clearly such facts as are accessible elsewhere, and he also enriches the subject materially by original contributions.

The pathological reports are very good. One of them in particular is of great value, as it throws much light on the obscure points of primary syphilitic disease of the arteries of the spinal cord and sudden paraplegia.
The publishers have hardly done their author justice. The illustrations are poor and the paper and binding not of the best.

Dr. Lewis's book won its reputation ten years ago as being one of the earliest of treatises on mental diseases in English which endeavored to refer the symptoms of insanity to a definite anatomical basis. It stood well as a clinical treatise also, but its special claim to popularity was its pathological and anatomical sections. In this, the second edition, the author has followed out his original plan. More than a third of the volume is given over to anatomy and pathology, and these subjects in this edition have been considerably added to, as was necessary by reason of the advances recently made. The book is especially valuable to those engaged in institution work and to those having the opportunity of seeing the pathological side of insanity.

This series of *International Clinics* is opened by Dr. H. C. Wood, with an article on cold as an antipyretic, which, though short, is written in the usual clear and concise style of the author, and consists in a brief summary of the various means of applying cold to reduce febrile temperature. Enzenburg of Berlin, reviews the treatment of tabes dorsalis in a most interesting way, for he has seen the gradual development of present methods. He speaks highly of Frankel's method of overcoming the ataxia by means of regulated exercises, and gives a warning against too much reliance on specific treatment. Among other articles of interest are Fournier's on the frequency of unsuspected syphilis, the continuation of Grancher's lectures on the treatment of tuberculosis, and the conclusion of Rosenheim's lectures on the treatment of chronic constipation.

**BOOKS, ETC., RECEIVED.**

Report of the Trustees of the New York Hospital presented to the Corporation at its Twenty-sixth Annual Meeting, July 11, 1899.

The Modern Use of Synthetics. By REYNOLD WILCOX, M. D. [Reprinted from the *Medical Porter-nightly.*]

The Record of Four Years (1895-1899) in an Exclusively Electro-therapeutic Clinic. By Margaret A. CLEAVES, M. D.

A Study of Some Conditions that lead to Fibroid Changes. By WILLIS S. ANDERSON, M. D., of Detroit. [Reprinted from the *Physician and Surgeon.*]
the pneumonic process as well as the general typhoid infection are both due to the bacillus of Eberth we still have the term "pneumo-typhoid," the use of which, however, should be subject to these strict limitations. Accuracy in terminology, says the author, is the first step toward a reasonable therapy, and the ill results of calling conditions by wrong names must inevitably lead to a less clear-sighted management of them.

Not to be Beaten.—The Indian Medical Record for August 2d is responsible for the following druggist story: "A gentleman received a note from his lawyer which he was unable to decipher. On his way to his office he met a friend at the door of a chemist's shop. The friend, after vainly attempting to read the note, suggested that they step inside and hand it to the chemist without comment. The chemist, after studying it in silence for a few minutes, stepped behind the prescription case, and in a short time returned with a bottle of medicine, duly labeled, and bearing directions. When the gentleman saw his lawyer he was informed that the note was a notice for him to call at his office between one and four o'clock p.m. of the following day."

Human and Bovine Tuberculosis.—According to the British Medical Journal for September 2d, a special committee of the Cape Town branch of the British Medical Association has submitted a report on tuberculosis in South Africa. There appears to be a general consensus of opinion that the disease is on the increase there among human beings; while as a curious fact it is mentioned that medical and veterinary opinion is practically unanimous in declaring tuberculosis almost nonexistent in cattle there.

A Nine-months-old Child as an Opium Habitué.—W. F. Boggess (Archives of Pediatrics, May, 1899; Medicine, September) reports a child nine months old, small, weighing only eight or nine pounds, but bright and well nourished. Six months before coming under observation the mother had begun administering laudanum for colic. The dose administered varied from four to twenty drops, and the daily quantity was from one to two drachms. While under the influence of the drug the infant was bright and apparently quite comfortable, but as soon as it was withdrawn there were pain and fretfulness. The drug was rapidly reduced in quantity, and the reduction was followed by a prompt recovery. The report is of interest from the fact that it is the earliest case of opium addiction on record, and also by the remarkable tolerance of the drug shown by so young a child.

"Imagino-therapy."—The Maryland Medical Journal for September 9th says in an editorial that all woman is (clinically) divided into four parts—blood, bowels, pelvic organs, and imagination. This is so well known to the profession that a simple statement of the truth suffices. The point at present urged is that the fact that an ailment is cured through the imagination does not prove that the ailment is imaginary. This second fact is not as familiar to the profession as the first; some may even be found to dispute it.

Through the imagination (as is well known) the arterioles of a sensitive woman will contract and relax, producing pallor or a becoming blush, according to the theme presented in her thought. In certain states of illness the whole cutaneous surface may flush and burn from the above cause, much to the distress of the patient, whose public life may be rendered miserable thereby.

As the vasomotor nerves of inward organs are probably subject to like impressions through the imagination, it is not unreasonable to suppose that acute or chronic congestive disorders of these organs may be greatly affected by this agency.

It is not wise that imagino-therapeutics, such as the use of hope, fear, expectation of relief, mental exhilaration, wonder, curiosity, should be pooh-pohed by physicians and left to the quacks.

A Proposed South African Post-graduate School.—According to the British Medical Journal for September 2d, a committee of the Cape Town branch of the British Medical Association is considering the formation of a post-graduate medical school in Cape Town.

A New Free Bath in Hoboken.—It is announced that Mr. Richard Stevens and his sister, Mrs. C. B. Alexander, are building a free public bath in Hoboken, and that it is expected to be ready for use by the 1st of October.

The Evolution of Dental Diseases.—In the Dental Cosmos for August, Dr. Charles H. Ward, in an exceedingly interesting paper entitled The Evolution of the Patient, read before the Seventh District Dental Society of the State of New York, traces in a most interesting manner the evolution of dental diseases as a consequence of the evolution of man himself. Commencing with the antiquity of man as established by paleontological researches, he follows the effect upon the teeth of his varied modes of living in the varied stages of his existence, the invention of weapons, the discovery of fire, the domestication of animals, and the gradual influences of civilization. He further considers the antiquity of the extraction of teeth, and views various tribal customs in which the teeth figure as trophies, badges, symbols, etc.

Yawning as a Hygienic Measure.—Lauder Brunton (Quarterly Medical Journal, January), in his inaugural address to the York Medical Society on Exercise and Overexercises, says: "For the development of the chest there is perhaps no exercise better than that which Nature has pointed out as a relief to fatigue—namely, yawning. For in this action the chest is expanded to the utmost both by the ordinary inspiratory muscles and by the accessory muscles connected with the arms. In cases where chest expansion is deficient, either from arrested growth in children or from disease of the respiratory passages or pleura, the movements of yawning repeated several times tends to increase the chest capacity. But this should be done where the air is clean and fresh and free from germs, because more air is drawn in and is drawn more deeply into the chest than in ordinary breathing, so there is a greater chance of microbes getting deeper into the lungs, if any should happen to be present in the air. Movements like those of yawning, though perhaps less extensive, occur when a skipping rope is used backward, and I do not think there is any better exercise for children with imperfect expansion of the chest than skipping backward. The movement of skipping forward is not nearly so good, as the inspiratory muscles are not used to the same extent, and the action tends rather to contract the chest than to expand it."
Original Communications.

DISPLACEMENTS OF THE HEART
IN LATERAL CURVATURE.
A STUDY IN THERAPEUTICS.

BY THOMAS E. SATTERTHWAITE, M.D.,
CONSULTING PHYSICIAN TO THE ORTHOPEDIC HOSPITAL, ETC.

Displacements of the thoracic and abdominal viscera are natural sequences of lateral curvature, and inasmuch as the deformity is usually most marked in the dorsal region, it is the contents of the thorax that are apt to suffer most. In the early stages of the disease or in slight cases the alterations of position or of function in the thoracic organs may be inconsiderable, but in advanced degrees of the deformity unnatural positions of these viscera may so seriously affect their functions as to disturb both respiration and circulation.

The large experience of Adams * led him to say, in speaking of the effect of lateral curvature on the general health: "While no affection can possibly be more variable as to its general symptoms and its influence upon the health of the patient than lateral curvature of the spine," and while "no symptoms such as would interfere with the general health of the patient may be present, even up to the middle period of life, although the evil day is put off, it nevertheless arrives sooner or later, and the patient suffers from functional disturbance of the thoracic or abdominal organs to an extent which leads to the belief that serious disease of these organs exists."

In regard to the functional derangement of the thoracic organs, he further says: "In slight cases of lateral curvature of the spine, when associated with general debility and occurring in girls, it is by no means uncommon for the patient to suffer from palpitation of the heart, with a disposition to fainting, etc., with feeble and irregular pulse." Adams adds: "The opposite view, however, is generally taken by those who see but few cases of spinal curvature, and the enfeebled condition of the general health, together with the associated functional disturbances, are regarded as the primary and essential affection to which the spinal curvature is merely secondary; but," he continues, "in the more severe cases of lateral curvature of long standing, where the heart becomes displaced and to some extent, perhaps, embarrassed by the contraction and deformity of the chest, palpitation, with some irregularity in its action, may become a more prominent symptom and lead to the suspicion of the existence of heart disease." And Adams quotes John Shaw, of London, who stated that he "had been consulted by several patients who had been treated for disease of the heart, though all the symptoms were caused by distortion of the spine," and adds, "I have known several patients about the middle period of life, afflicted with severe spinal curvature, so impressed with the idea that they were suffering from disease of the heart that the highest medical authorities failed to remove such impression." And he concludes: "Many similar cases, and several in which the symptoms referable to the interference with the functions both of the heart and lungs have been much more severe, have been under my observation in hospital and private practice." As an illustration of the unnatural division of the thoracic cavity in lateral curvature, he alludes to a specimen in the collection of the Royal College of Surgeons in London, where the space between the bodies of the vertebrae and ribs was reduced to three fourths of an inch.

Bouvier * speaks of a case where the heart could scarcely find room for itself in the narrow space left by the lung, and in fact that it appeared forcibly applied to the thoracic wall. Bradford and Lovett † confirm these views by saying: "The lung in the convexity of the curve is compressed and flattened. The aorta is necessarily displaced. The heart is generally found displaced toward the concavity of the curve in severe cases."

These statements from well-known orthopaedists, widely separated in locality and spheres of influence, go to show that there is a common belief in various parts of the world that lateral curvature tends to disturb the functions of heart and lungs.

Indeed, Adams appears to approve of Bouvier's statement that "individuals thus affected rarely live to old age and fall victims either to phthisis or heart disease." How far this is true I am unable to say, but I have seen a number of cases in which it seems to me that the curvature was the principal factor in determining cardiac and, associated with it, pulmonary disease. And conversely, I may add, I have seen improvement in the curves of the spine, and corresponding to it an improvement in the position of the heart, without other remedies, so favorably affect the circulation, respiration, and general health that I am disposed to believe with Adams that the lateral curvature is, in some cases at least, the fons et origo of the functional disturbance rather than the cachexia which is so apt to attend it. My experience has been chiefly, but not altogether, confined to girls between the ages of twelve and twenty-four. Lateral curvature is comparatively infrequent in boys and young men. The chief curve I have usually found in the dorsal region and to the right. The heart has been in all these cases displaced, the apex varying in position from a point three fourths of an inch to the right of the nipple to a point an inch to the left of it. I have found the usual difficulty in determining the causes. Phthisis, pleurisy, especially of the

† Orthopedic Surgery, 1890, p. 14.
suppurative form, post-scarlatinal paralysis, rickets, and the carrying of unusual weights have appeared to be determining causes. While pain is an acknowledged sign of curvature, I have not found it constant or confined to any special locality. It may be referred to the spine or to the parietes of the chest or elsewhere. It is usually on the side of the principal curve. Palpitation and dyspnoea are not uncommon.

My general plan of treatment, varying according to individual cases, has been the employment of—

1. Resistant exercises with forcible pressure.
2. Carbonated brine baths.
3. Massage.
4. Faradisation.
5. Nutrients.

My system of exercises is a little on the lines of the system laid down by Bernhard Roth, of London.* I give his plan in brief in order to compare it with my own. It is as follows:

1. The patient lies on the back, with arms to the sides; hands supinated. Several deep inspirations are then taken.
2. The patient in the same position extends the arms above the head and inspires deeply several times.
3. In the same posture the patient rotates the head and flexes it laterally.
4. In the same position the arm is circumducted.
5. In the same position one hip is circumducted, then the other.
6. In the same position the patient extends the arms forward and backward.
7. The patient lies prone and circumducts one hip, then the other.
8. The patient now sits on the couch and the ankle is circumducted.
9. The same, but the operator resisting.
10. The patient sits astride a narrow bench or couch prepared for the purpose and flexes the trunk, the operator resisting.
11. The patient grasping pegs on a pole, the operator rotates the pelvis.
12. The patient lies on a couch with the head projecting, while the head is flexed by the operator.

These exercises appear to be in the right direction, but are mild as compared with my own. They would be chiefly applicable, I think, in the earlier stages of the disease or in slight curves. I should prefer the more elaborate and scientific method laid down by Dr. R. H. Sayre † to Roth’s system. Assuming that the scheme of exercises will vary somewhat according to the nature and extent of the curve, I now give my ordinary method in the fully developed double curve.

The system is mainly that of Professor Hartelius, of Stockholm, as modified by my associate, Dr. H. V.

---

Barclay, and myself. The first step before each exercise is to make the patient assume a posture that in itself tends to reduce the deformity, and have this position maintained so far as possible during the exercises.

1. The patient, standing with the hands to the side, raises both arms (fully extended) laterally upward, so as to be parallel. At the same time the patient raises herself on her toes. The arm movement elevates the scapula and the ribs, pulls on the spine, and both by virtue of the vertebra, rotates them upward and toward the median line, and in so doing elongates the spine. Put a patient with this special deformity on a measuring block, let her go through this motion, and the spine will be seen to elongate perceptibly. I have seen it elongate two tenths of an inch. This movement of raising the body on the toes tends not only to elongate the whole body, but also to correct the position of the pelvis.

2. The patient, resting against a suitable support, such as the horizontal bar of the gymnasium, applying the front of the pelvis to the bar, extends the arm corresponding to the dorsal concavity upward, the operator resisting. The low shoulder is thus raised, while the dorsal and all compensatory curves in lumbar and cervical regions are more or less straightened out.

3. The patient, standing in the same position and with the same support, places behind her head the hand of the arm corresponding to the dorsal concavity. The other hand grasps the hip of the other side. Now the patient flexes her body at the hip joint and then erects herself, carrying the body a little beyond the vertical line. The operator stands behind, places his hands on the convexity of the dorsal and lumbar curves and makes lateral pressure, resisting the erection of the body.

By this method, the patient having her spine supported and in a measure straightened by the operator, the erectors of the spine, the lumbar and gluteal muscles, are brought actively into play.

4. The patient now suspends herself by the hands from the ordinary horizontal bar, which is raised at one end a peg or two higher than the other, so that when the patient hangs by both hands the low shoulder is raised. The weight of the body is now thrown to the side of the convexity, taking the strain off the muscles over the curvature, while the spine is more or less straightened by the weight of the body and extremities. In this position the patient flexes the head backward, the operator resisting. This latter movement tends to reduce the secondary curve in the cervical region by bringing the muscles of the neck into play equally on both sides.

5. The patient now places herself prone on a flat table with the arm corresponding to the dorsal concavity stretched forward. She then raises the corresponding leg and opposite shoulder. This exercise flattens the “hump” in the back. Under this combined move-
ment the dorsal curve recedes very perceptibly during the exercise in the direction of the median line.

6. Patient lies in a semi-recumbent position on a couch with the legs hanging over the extremity. The arm on the side of the dorsal concavity is placed behind the head; the other hand grasps the opposite hip. The operator now fixes the patient's knees, while she erects her body.

7. No. 7 is a repetition of No. 3, but in a sitting position, the knees being supported in front. This support steadies the pelvis.

8. The patient on the couch, with the upper hand over the head, lying on the side corresponding to the lumbar concavity, raises the leg as far as possible. This movement, which may be resisted, tends to eradicate the lower curve.

9. The patient sitting on a chair with her body bent forward, with spine as straight as possible, extends the arm corresponding to the dorsal concavity upward, while the other arm is carried down. These movements are done simultaneously, the operator resisting each movement. Then the arms resume the original position without resistance. The muscles of the cervical region are exercised by the ascending arm and the dorsal muscles by the descending arm.

10. The patient in the standing position raises the straightened arm corresponding to the dorsal concavity to the perpendicular. The other arm, still straight, is carried backward and inward. These movements, like those of No. 9, tend to straighten dorsal and cervical curves. They should be carried to the limit.

11. Patient suspended from the bar by the hands raises both knees. The abdominal and psoas muscles are brought into play, the body being held in a favorable position.

12. Patient suspended from the bar extends both legs toward the side of the lower convexity. This exercise tends to straighten the lumbar curve.

13. The patient standing with leg of side corresponding to lumbar convexity in front, and leaning forward, carries both arms backward and inward to the limit. This exercise carries the shoulder blades toward the spine and tends to remedy their false position.

14. The patient, lying prone across a narrow table, with the arm corresponding to the dorsal concavity extended, the other hand on the corresponding hip, both ankles being fixed by the operator, erects the trunk several times successively.

15. The patient, suspended from the bar, separates the extended legs under resistance. This movement tends to lessen the lower curve.

16. The patient, lying on a table and on the side corresponding to the lumbar concavity, with the trunk extended beyond the edge of the table, the ankles being fixed by the operator, with the arm of the depressed shoulder extended over the head, carries the trunk upward to the limit. This exercise is very effectual in straightening the lumbar curves, while the extended arm tends to straighten the dorsal curve.

In the beginning, or with feeble patients, these movements may require assistance by the operator.

In the majority of cases there is advantage in using physical force in the reduction of the deformity. The "hump" should be pressed down forcibly when the patient is lying prone on a hard surface. I have never known this method to give pain; in fact, it is agreeable to the patient.

Forcible correction, the redressement forcé of the French, has been recommended and resorted to by various orthopaedists. Indeed, there are, as is well known, appliances adapted for forcible correction. Barwell describes a method which he calls rhachilysis. My experience indicates that if the operator is strong enough, and can give the requisite time, forcible correction can be accomplished with a fair degree of success by manual means without the assistance of any mechanical appliance. But it is not unlikely that mechanical contrivances for forcible correction may be used with advantage in correcting certain classes of these deformities, in conjunction with resistant exercises and manual pressure.

In cases of bony rigidity without complications, it is folly to expect success without using forcible correction. It is astonishing how much double pressure can be borne with impunity.

If there is also Pott's disease, or a reasonable suspicion of it, and such cases will confront us, forcible correction would, of course, be a very improper procedure in connection with resistant exercises.

Forcible reduction rests the overstretched muscles over the convexity and reestablishes their tone. The projecting scapula will sink toward the normal position.

Massage to the muscles of the back is not only a valuable adjunct, but is enjoyed by the patient. It should be given when the patient is lying with the back bared and upon a well-upholstered couch, and at the end of the exercises.

The faradaic current may be applied occasionally during the entire course of treatment. It should be employed for a few minutes only, so as to actively contract the muscles of the back. As in any disease, each patient has to be treated with a view to the individual case, but the methods described are those that are applicable to ordinary uncomplicated cases with the S-shaped curve.

The use of carbonated brine baths is of material aid in the treatment, the results being more rapidly attained when baths and exercises are combined. In private practice they should not be neglected.

I advocate the use of the warm carbonated brine baths of moderate strength during the entire course of

* Lancet, April 27, 1889, p. 531.
treatment. The strength of the brine should be from three fourths per cent. to one per cent., and of the carbonic-acid gas from one fourth to one half per cent.

The stronger carbonated baths applicable for chronic valvular diseases of the heart are not advisable.

In a majority of cases I use (to supplement the treatment) tonics, such as iron and strychnine, and nutrients, such as cod-liver oil and the malt extracts, and I use them for long periods. Some preparation of malt I find desirable in nearly all of these cases.

The following are illustrative cases:

Case I. Spinal Curvature; Anemia; Cardiac Displacement; Corpulence.—Miss II., aged twenty-four years, Havana, Cuba, a young lady of large build; height, five feet six inches and a half, weighing about a hundred and sixty-three pounds, came to me for treatment July 10, 1898, wearing a spinal brace.

September 1, 1898.—On examination it was found that she had, on standing, the usual lateral curve to the right in the dorsal region; pelvis rotated and tilted. Left breast unduly prominent. Pale and anemic. An excess of flesh, chiefly about the waist and hips. Short-winded on slight exertion, with deviation of about an inch and a half from a straight line in the interscapular region, and deviation of an inch to the left in the lumbar region. Apex of heart to left of nipple an inch, and an inch and a quarter below the extended intermammary line. Patient given iron and strychnine and the brace removed.

October 19th.—One half per cent. carbonated baths given twice a week. Resistant gymnastic exercises daily under direction. Massage and electricity to spinal region.

November 11th.—Three fourths per cent. carbonated baths once a week.

December 2d.—Under this treatment, continued for three months, though the course was interrupted by an attack of influenza, the spinal deformity has been so far rectified that the greatest deviation from the normal line on standing was only three quarters of an inch in the dorsal region, and in the lumbar region three eighths of an inch.

January 2, 1899.— Apex three inches from the median line and one from the intermammary line. The patient was now suddenly summoned to Havana. She also lost about fifteen pounds in four months, a little less than four pounds a month, and was greatly improved in her physical condition.

It will be seen by Fig. 1 that while the spine was being straightened the heart (Fig. 2) was gradually carried inward toward the median line.

After treatment had been begun the brace was entirely dispensed with. This case was published without the diagrams and with the omission of some of the details in the Post-graduate for March, 1899.

Case II. Lateral Curvature; Cardiac Displacement.

—J. C., a patient sent me by Dr. E. S. Holt, November 13, 1897.

Age, sixteen years; weight, a hundred and thirteen pounds and a quarter; height, standing, fifty-eight inches and a half; sitting, thirty-one inches; chest, 29–31.5.

Curvature of the spine was noted about five years ago. Has had pneumonia and pleurisy since the curvature began; catches cold easily; has sore throat often, so have her brothers and sisters; was feeble as a child. Finds it hard to sit up; has the common dorsal curve to the right. Left breast prominent. Often has pain in left side of chest; thinks it is from dyspepsia. The left hip is higher than the right. The anterior superior spine of left side is lower and more forward. Is not short-winded; has no thoracic pain, but suffers from insomnia; she wore a brace about two years. Patient is robust. Restraint exercises were given her daily under
my directions for an hour for about nine weeks, and then three times a week afterward. The improvement in the curve and in the position of the heart is shown by Figs. 3 and 4. Patient has broadened the chest under treatment an inch and a quarter, and has an inch and a fifth more expansion. Has lost two pounds in weight, but has improved greatly in physical appearance.

Case III. Spinal Curvature; Moderate Cardiac Displacement.—K. G., aged thirteen years; height, 57.5 inches. Two years ago noticed a crook in her back; thinks it came from carrying an infant, possibly from a fall that caused depressed fracture of her skull. Often has pain in right side. Left breast most prominent. Left hip highest, left anterior superior spine most forward. Wore a brace about six months; wears none now; took it off during the gymnastic treatment and feels better without it. The diagram illustrates the results under resistant exercises. (See Figs. 5, 6, and 7.)

![Fig. 5](image1)

![Fig. 6](image2)

![Fig. 7](image3)

In this case, and in Case IV, the tracings, kindly taken by a well-known orthopedic surgeon of the Orthopedic Hospital, must be studied in connection with other measurements. The tracing of May 8, 1899, shows an apparently excessive deformity, but measurements made in this way, as in fact all systems of measuring these deformities, are more or less misleading, even where they are, as in this instance, quite accurate. In this particular tracing the deformity is exaggerated by the fullness of the muscles, which by exercise, massage, and electricity have been greatly increased in size. But Fig. 5 shows that in this instance the compensatory curves in the lumbar and cervical regions have been improved, and in fact that there has been a progressive improvement in all the curves.

Patient has been under the use of maltzyme for two months and upward. She has gained in weight several pounds, and also in general condition.

Case IV. Spinal Curvature; Rigidity of Spine; Rickets; Debility.—L. F., aged sixteen years; height, 52.6 inches standing; twenty-eight inches sitting; weight, eighty-one pounds. The following history was kindly furnished by Dr. Ethel D. Brown, under whose observation she came, and by whom she was first seen in February 14, 1895. Patient as a baby was weak, and sickly as a young child. At that time the trouble had only been noticed by the family a few weeks earlier. The first symptoms she complained of were pain in the lower part of the spine and a tired feeling. Then the mother noticed that one shoulder was larger than the other. Even at that time, four years ago, the spine was quite rigid. The greatest convexity of the deformity was toward the right, opposite the sixth, seventh, and eighth dorsal vertebrae, the deviation being at the highest point half an inch from the median line approximately. Considerable rotation. Left shoulder slightly lower. The patient was put on tonics and given exercises from the above date until the autumn, three times a week, except for a few weeks when she was in the country. In the autumn she left to go to the country, the parents preferring to have her wear a brace to taking the exercises.

Patient has had scarlet fever. The principal cause of the disease was rickets. Patient had not complained of palpitation, was not short-winded, but suffered from frontal headache. Pelvis rotated and tilted. The crest of the left ilium is about an inch higher than the other, while the anterior superior spine is turned downward and thrown forward. On January 13th patient was wearing a brace. She wore one for a while when tired, but has now totally dispensed with it. The patient was put on maltzyme, and later on maltine, and has been gradually improving in her general health.
May 16, 1899.—Height, fifty-three inches; weight, eighty-two pounds and three quarters. Patient has gained an inch and a half in the chest measurement and two inches and three quarters in expansion.

The diagrams No. 8 and No. 9 show the changes under treatment. The curves are straightening a little, while the heart's apex has moved inward.

This case was selected as a bad one, in which little if anything was to be expected; indeed, such was the deficiency in height, weight, and bodily strength, and so great the rigidity of the spine, and debility with exceeding deformity, that the case was thought typical to test the value of this method in bad cases. In fact, a celebrated English authority, when asked whether his system of exercises would benefit this particular case, replied that he would not think of applying it.

The case is also remarkable in several other ways. No baths were given. The treatment was merely resistant exercises with forcible pressure and nutrients.

These tracings (Figs. 8 and 9) also were kindly taken for me by a well-known orthopaedic surgeon. The third and last tracing (Fig. 10), taken over the tenth dorsal on May 8, 1899, showed that the patient had apparently greater deformity than ever. Undoubtedly at that point the prominence was marked, and indeed increased to a slight degree in the mid-dorsal, but by looking at Figs. 8 and 9 under date of April 24th and 26th, about two weeks earlier, it will be seen that on the whole there was an improvement in both upper and lower curves and in the heart's position—in fact, notwithstanding the extreme rigidity that had existed for years in this case, it was to a degree amenable to treatment. In this connection it must be added that the alteration in the curves of the tracings are in a measure also in this case, as in the previous one, due to the development of the muscles of the back under this special treatment.

In measuring a spinal deformity I let the patient stand with the feet together, hands to the side, and shoulders thrown back, the head and body being held in as erect a position as possible. I then trace the spinous processes, the angles of the scapula, and the levels of the crests of the ilia on the bare skin with a dermographic pencil and take off a tracing with the ordinary vegetable-fibre tissue paper used by artists. Of course, antero-posterior curves do not show by this method. And yet I may add here incidentally that antero-posterior curves are apt to be greatly improved during treatment, as shown by the "popping up" of spinous processes that at first may have been buried out of sight.

But while I have adopted the method of measuring the amount of curves as mentioned, I have not relied wholly on it, but have, as already stated, supplemented it by the lead tracings, as shown by Figs. 7 and 10, and also by photographs and X-ray pictures. From the tracings of the scapula it will be seen that the results of this treatment are that the inner borders are brought nearer the spinal column and assume more nearly the vertical or normal line.

It is quite unnecessary, I feel sure, for me to state here a fact widely recognized by orthopaedists, that every system of measurement heretofore devised has proved more or less unsatisfactory. A few of the objections are as follows: Photography rarely gives one a sufficiently distinct picture of the deformity. X-ray pictures are difficult to make. We have not as yet mastered the technique of them. Lead tracings may exaggerate the deformity, and are therefore deceptive.

The method I employ is also apt to be misleading, I may admit, especially if the patient does not stand as erect as possible. But it is a simple method, and if carefully carried out is reasonably accurate. So, also, I may say with the method I employ in mapping out the heart, as seen in Figs. 2, 4, 6, and 9.

In this latter procedure it is noted that I aim to draw a horizontal line through the nipples and intersect it with a vertical line drawn from the episternal notch to the umbilicus.

In a sound person this first or intermamillary line is practically horizontal; the vertical line is the median line of the body. And the point of intersection of these two lines should furnish us with a good fixed point from which to make cardiac measurements; but in lateral curvature the point of intersection of the two lines is not a fixed but a constantly shifting point during treatment. For, as the spine becomes straighter, the fixed point gradually moves to the right and a little up or down, because the intermamillary line is not horizontal, owing to the bulging of the breast. However, in clinical work we are obliged to adopt certain fixed standards as to the landmarks of the body, and with due allowance made in this case, as in others, the results will, I think, be sufficiently accurate for practical purposes. To avoid confusion, I have inserted only a single vertical and a single horizontal line in each case (see Figs. 2, 4, 6, and 9).

It must not be thought that I am inveighing against spinal supports. I have used them in lateral curvature at various times in my practice, and have been satisfied with the results they have given. But a support is palliative rather than curative. Often the patient finds that he is gradually getting worse, notwithstanding his support. The method I have advocated has, I hold, a much wider application and is more scientific.
It is applicable more or less to all stages of the deformity, and is capable of yielding good results both in remedying the curvature and the displacement of the visera, provided the patient is willing and able to cooperate with the physician. Just how much benefit can be secured by the method in old cases, or where there is considerable rigidity, I am not prepared to say, but I am satisfied that it is capable of doing something for circulation and respiration even in the most advanced cases.

Gymnastic exercises, however, such as are given for lateral curvature in the ordinary perfunctory manner in schools and gymnasiums, will not accomplish much if the patient is a delicate subject, or the case is advancing rapidly. Special exercises adapted to special deformity are requisite. Resistant exercises also are needed, and with them forcible pressure.

Briefly, treatment by the method advocated is the one that gives the largest promise of good results in lateral curvature. Spinal supports are chiefly useful in mild cases as temporary expedients, or as a last resort.

7 EAST EIGHTH STREET.

REMOVAL OF A FOREIGN BODY FROM THE BRONCHIAL TUBE
THROUGH THE TRACHEAL OPENING.
REPORT OF A CASE.*

By A. COOLIDGE, Jr., M.D.,
BOSTON.

The presence of a foreign body below the larynx is a serious accident, and one in which prompt and proper action may be rewarded by saving the patient's life. Such cases commonly come under the care of the general surgeon, who, if there is marked obstruction to breathing, or if he is persuaded that there is something in the trachea, often does tracheotomy at once. The danger from tracheotomy is slight in comparison with the danger from a foreign body impacted in a bronchus. A body loose in the trachea often flies out of the tracheal wound; a body impacted in the larynx can be reached easily from below, but if it is in a bronchus it is only with good luck that it can be got out unless it can be seen.

Reflecting mirrors and angular instruments introduced into the tracheal wound are difficult or impossible to manage. It is possible to introduce a straight speculum into the trachea, and by bending the upper part of the body and head backward and to one side, to push the speculum downward, so that its axis is a continuation of the axis of the lower part of the trachea. This has been described by Schroetter,† and worked out in detail by Picniaczek,* who has removed foreign bodies and also treated locally the mucous membrane of the trachea. By proper light, not only the trachea, but often the whole length of the right bronchus and much of the left can be seen. This is made easier by a modification by Killian † of the methods and instruments of Kirstein. Killian introduces straight specula well into the bronchi, taking advantage of the mobility of the lower trachea and bronchi, which permits considerable straightening, or bringing into line, of the bronchus under investigation. In cases where there has been no tracheal wound he has passed a long straight tube through the mouth and larynx, and even into a bronchus:

The case which I report simply illustrates the ease with which a foreign body, that without this method would be extremely difficult to find, can be removed from a bronchus:

T. J. D., aged twenty-three years, a teamster, was admitted to the Massachusetts General Hospital May 11, 1898, in the service of Dr. A. T. Cabot, who kindly turned the case over to me. The patient had worn a tracheotomy tube for twenty years on account of stenosis of the larynx. His last tube was made of hard rubber, and was several months old. Twelve hours before admission the tracheal tube had become detached from the shield and had been inhaled, causing severe coughing and distressed and noisy breathing, which, although less severe, was still present when he was admitted.

Examination by X ray was negative. The patient was etherized and put on his back with the shoulders over the end of the table and the head held downward and rotated to the right side. The tracheal opening was enlarged downward. Not having any other straight tube of the proper calibre on hand, I used a urethroscope half an inch in diameter and three inches long, a little short for perfect examination. This was passed through the tracheal wound with the stylet in place, turned downward, the stylet withdrawn, and the speculum without any difficulty pushed down the trachea to within about an inch of the bifurcation. For illumination a head mirror was used with reflected sunlight, and this illuminated the field perfectly.

The foreign body was seen in the right bronchus, the upper end about half an inch below the bifurcation; it was seized with a long pair of alligator forceps introduced through the speculum and removed without difficulty. The patient suffered no ill effects from the operation.

During the whole time respiration was carried on easily through the speculum, except for attempts at coughing at first, which soon subsided. There was no inconvenience from secretion.

The trachea in the adult is from four to four inches and a half in length and from three quarters of an inch to an inch in breadth, being distinctly larger in the male than in the female. A low tracheotomy will cut off perhaps an inch, leaving from three to four inches to the bifurcation.

† Münchener medicinische Wochenschrift, No. 27, 1898.
The histories of cases of foreign body in the air-passages treated expectantly show so large a mortality, especially from septic pneumonia, that I venture to suggest the following rules for discussion:

In case of a foreign body of a size large enough to make it improbable that it has got lower than a primary bronchus, immediate tracheotomy and exploration by means of straight tubes, as large as possible, with good illumination, offers by far the safest course to pursue. If the foreign body is of smaller size, and the physical signs point to its presence in a secondary bronchial tube, operative interference is justifiable if there is a good chance of reaching it after illuminating the primary bronchus, as would be the case especially on the right side.

It should always be borne in mind that a body loose in the trachea is much less dangerous to the patient than the same body impacted in a bronchial tube, and consequently everything which excites violent respiration should be carefully avoided. On this account it is much better to do tracheotomy with cocaine than under an anaesthetic. Neither is it necessary that the patient should be anaesthetized for the introduction of the tracheoscope. In special cases it may be possible to avoid tracheotomy by introducing straight tubes through the glottis from above, but if the foreign body is being rattled to and fro in the trachea it would hardly be justifiable to run any additional risk of its being inhaled. Even when the foreign body is in the larynx, in such a position that there is considerable danger of pushing it downward in attempts to get it out, it may be safer for the patient to do tracheotomy and reach it from below than to run the risk of its being inspired and impacted low down.

It should be added that thorough surgical cleanliness is of vital importance where the principal danger lies in septic pneumonia.

A NEW SERIES OF THERAPEUTIC AGENTS.

By KARL SCHWICKERATH, Ph. D.

(Preliminary Report)

Among the oldest and most important remedies of inorganic chemistry belong, without doubt, the salts of iron, mercury, silver, and copper. Compounds of the last three elements have found a very extended application as antiseptics—particularly mercuric chloride (sublimate), silver nitrate, and copper sulphate. The chief objections to the use of these germicides are, however, that they are decidedly irritating, and they lower the vitality and resisting power of the tissues. The reason for such action we must seek in the fact that these compounds possess too great a chemical affinity for animal tissue, or for the constituents of the cell. Therefore, we very often find that the most powerful antiseptic agents, especially when used in stronger solutions, considerably retard the healing of wounds, and consequently the practitioner frequently obtains results just contrary to his expectations.

Concerning the operation of an antiseptic agent we still know very little. Most probably the chief action of germicides consists in this—they influence the soil in such a way that thereby the conditions so essential to the life of micro-organisms become unfavorable. We know that a series of metallic salts enter into peculiar combinations with certain proteid substances, and recent investigations have demonstrated that the leucocytes are the exclusive agents of absorption and transportation through the circulation of mercury, iron, and silver compounds. The multinuclear and uninnuclear leucocytes are principally engaged in this work. If, therefore, a solution of sublimate or silver nitrate is brought into contact with a wound or with mucous membrane, chemical reaction will follow. The metallic base is gradually absorbed, while the acid portion reacts with albuminous substances, which reaction manifests itself, for instance, by coagulation. From this fact the idea suggested itself that possibly soluble compounds of mercury and silver with such substances as have a more intimate relation to animal tissue might be comparatively non-irritating.

The thought occurs at once to consider nuclein; the more so as the theory has been advanced that most probably the nucleins play a very important rôle in the transportation of iron. Hence my task was before me.

The main difficulty, however, consisted in preparing a pure nuclein in large quantities by a process not too complicated. I have succeeded in accomplishing this, obtaining a pure nuclein in the form of an almost white amorphous powder. For crude material I employ yeast, which is comparatively rich in nuclein and is available in large quantities. This pure yeast nuclein, to which I have given the name of nuclein—in order to avoid confusion with certain nuclein preparations of commerce of more or less doubtful origin—is soluble in warm water, but insoluble in alcohol. Its solubility in water is increased by the addition of dilute alkali. If now we add to a solution of nuclein in water freshly precipitated mercuric oxide, the latter is gradually dissolved. This reaction is accelerated by gentle warming. If, to the solution thus obtained, a large quantity of alcohol is added, a voluminous white precipitate is formed, which represents a new chemical compound of nuclein with mercury. The silver, copper, and iron oxides react in a similar way with nuclein.

These new compounds are readily soluble in water, particularly warm water, with neutral or faintly alkaline reaction, and they contain the metals in true chemical combination. They do not precipitate solutions of albuminous substances. Consequently, my purpose was accomplished. I had succeeded in preparing soluble compounds of mercury, silver, copper, and iron with a proteid substance, nuclein, which I expected would have very slight chemical affinity for the tissues—that is, they
should display very little chemical reaction, but physiological action only.

My next task was to determine whether these new compounds were able to take the place of the inorganic compounds, mercury bichloride, silver nitrate, and copper sulphate, in the treatment of infectious inflammations.

Only practical clinical experiments could decide this question. Laboratory experiments, or test-tube experiments, are to my mind almost useless when we desire to establish the value of an antiseptic agent that is intended for the disinfection of any part of the living organism. If the problem is to determine the value of a disinfecting agent for general use outside the body, then, of course, such experiments are a necessity and of the greatest utility. In the case of the animal organism, however, we have to deal with different conditions. As I have already mentioned, with an increased activity of the disinfecting agent there is also generally a greater increase of properties detrimental to the protoplasm. Again, a disinfecting agent might give results in the test-tube experiment with an artificial culture medium, whereas in the treatment of wounds it becomes practically worthless. The following striking example will illustrate this: Iodoform, per se an indifferent substance, becomes a very powerful germicide when brought in contact with wounds. On the other hand, under the same conditions, a watery solution of mercuric bichloride, which displays most powerful antiseptic activity, become more or less inert through the influence of the secretions of the wound and the bacteria.

Clinical experiments with these nuclein compounds have not only fulfilled all expectations, but they have exceeded them. Practical prolonged investigations have shown that these new compounds possess all the therapeutic advantages of the respective inorganic salts, without their disadvantages. As one would naturally expect, the mercury compound apparently displays the greatest activity. In the following paragraphs I submit a few data concerning the different compounds.

Nucleol.—A pure nuclein from yeast. It exists in the form of a whitish powder, readily soluble in warm water; insoluble in alcohol.

Mercurol.—A nucleide of mercury, containing about ten per cent. of the latter in organic combination. It exists in the form of a light brownish-white powder; is soluble in water, especially warm water, with faintly alkaline reaction; insoluble in alcohol. It does not precipitate albuminous liquids and is not precipitated by alkalies. In preparing solutions, instead of plain distilled water, physiological salt solution (one drachm of sodium chloride to one pint of water) should be employed.

Nargol.—A nucleide of silver, containing about ten per cent. of the latter. It exists in the form of a light brownish-white powder; is readily soluble in warm water, with faintly alkaline reaction. It does not coagulate albumin and is not precipitated by alkalies or ordinary reagents for silver. When solution of sodium chloride is added to a nargol solution no precipitation takes place. After standing for a long time, however, a gradual decomposition and separation of silver chloride occurs.

Cuprol.—A nucleide of copper, containing six per cent. of the latter. It exists in the form of a green powder; is readily soluble in warm water. Its solution does not coagulate albumin, and is not precipitated by alkalies, etc.

Ferrinol.—A nucleide of iron, containing about six per cent. of the latter. It exists in the form of a cinnamon-brown powder; is readily soluble in warm water, with neutral reaction; does not coagulate albumin, and is not precipitated by the ordinary reagents for iron. The iron is here present in a stable organic combination, which should render the product valuable when prompt absorption is desired.

More detailed information as to the chemistry of these new products will be published in the near future in some chemical journal. The house of Parke, Davis & Co. will undertake the manufacture of these products.

March 30, 1899.

THE AMOEBA CILIARIA IN DISEASE.

By HENRY GEREON GRAHAM, M.D.,
CHICAGO.

The object of this article is to show the manner of origin of some of the acute infectious diseases. An attempt will be made to show the relation existing between malaria and septicaemia, malaria and typhoid fever, typhoid fever and pneumonia, and typhoid fever and purpura haemorrhagica, although it is usually believed the last two have little in common. Others might be added to this list, but those enumerated will suffice for the present. It will be shown how the typhoid bacillus is sustained until it can reach a new and favorable environment. We shall see why the solitary glands, and particularly Peyer's patches, sustain the brunt of the attack, and why there may be severe diarrhea in one case and none in another. Finally, it will be shown what is the cause of the rose spots in typhoid fever and what that of the minute haemorrhagic spots in purpura haemorrhagica.

The cause of all these will be sought in water.

If only a few drops of water are taken at random and placed upon a slide, few or no organisms will be seen. In order to ascertain the variety and quantity of organic life present in a given water, a comparatively large amount must be taken and the organisms collected into a few drops. A litre is a convenient quantity. If practically all the motile and most of the non-motile organisms in a litre of water are collected so that these are seen in the first few drops placed upon the
slide, a good idea is obtained as to the amount of organic life present in a given specimen.

If a given water is examined in this way it will be noted what organisms are common and what are rare, what are constant and what accidental.

Any one who will take the trouble to do so will find that in the hydrant water as it comes from the lake, the various micro-organisms in order of frequency will be seen to be as follows:

1. A cocccus or diplococcus.
2. A bacillus, the Bacillus proteus vulgaris.
3. The Amoeba ciliaris.

The diatoms and the desmids are not included in the above for the reason that they are probably in no degree pathogenic. However, as they are frequently present in the urine, in diseased conditions, it is possible the siliceous frustules may cause irritation of the uriniferous tubules of the kidney.

Of these organisms, J. H. Wythe says: "Diatoms inhabit the sea, others fresh water. They are so numerous that scarcely a ditch or cistern is free from specimens, and they multiply so rapidly as to actually diminish the depth of channels and block harbors."

The first, or monococcus, is so common that it exists in almost every drop of water. It is the smallest body visible through an ordinary microscope that is found in water. It multiplies by division of the mother cell. When in the process of division, the latter appears as a diplococcus. It is a facultative microoccus, and can exist for at least seven months deprived of air and light. When thus shut in, it grows for the most part in clusters in the form of a circle. The individuals in a cluster may be as few as fifty or less, or they may number millions. A large cluster has a dull grayish appearance. At times some of the diplococci persist, and these, with others, may form chains that look like streptococci, only the chains are short, consisting of four to six up to ten individuals. Many single cocci existing apart from the clusters are always to be found. Most of these are exceedingly active, moving apparently by means of flagella.

The second micro-organism, the Bacillus vulgaris, though frequently met with, is not nearly so common as the micrococcus. It exists in great quantities in water that has become slightly tainted with organic matter, but is not rare in the best hydrant water. Ordinarily it does not form spores, but may do so under certain conditions. When spores form, they are found in the end of the bacillus. In hydrant water they are sometimes seen as delicate and very long spiral threads. These divide transversely to form the bacilli, which usually exist singly. They often, however, form pairs, the connecting substance between two bacilli persisting. They are actively motile whether found singly or in pairs. If a bacillus containing a spore is stained by the Ziehl-Neelsen method, the spore is stained red, the rest of the bacillus blue.

The third in point of frequency are the amoebae. In searching for infusoria in fresh water, four species of amoebae will be found, Amoeba princeps, A. verrucosa, A. diffluens, and A. ciliaris. In almost every cup of water drawn from the hydrant some one of these organisms, in some stage of development, is usually to be found. The last occurs more frequently than all the others combined, and as a morbid agent in the production of acute infectious diseases is a most important organism. Scarcely a litre of hydrant water can be drawn in which this organism, in some stage of its development, is not present. The ovule is the form most frequently encountered. This is usually perfectly round, sometimes slightly elongated, and is a luminous body. A tenacious ovule membrane forms an excellent protection for the young amoeba against mechanical or chemical injury. The young amoeba within this ovule membrane form a sphere, the individuals being ranged upon the surface and anchored to its centre by means of a filament. Between the ovule membrane and surface of the sphere is a clear interval that contains no granules. When the ovule membrane bursts and the sphere is set free, the young amoeba are at once dispersed, they being by this time very actively motile. The filament develops into a protobasid by means of which the young amoeba obtains its food. At this time they may be seen in large numbers gathered about any organic matter that may be present and feeding upon it with great avidity.

It is in the warm summer months that the sphere of young amoebae is broken up immediately the ovule membrane bursts. As the weather grows colder, the sphere remains intact longer, and by October and November it goes tumbling across the microscopic field like the living thing that it is. With the growth of the young amoeba, the protobasid gradually disappears. In its place in the adult is a small opening—an oscule—which serves for a mouth. This is found near the apex, in that part free from granules, and which may be designated the head. Through this oscule the amoeba takes in a small globule of water, or air and water, whatever may be floating in it, and soon expels it again. This globule is sometimes retained for a considerable period. This seems to be the rule when there is floating in it some minute form or fragment of organic life. This is apparently the manner in which the organism procures its food. A number of these globules are often to be seen in an amoeba and appear as vacuoles. It is often noticed that when one is feeding, all are feeding; when one is at rest, all are at rest.

The Amoeba ciliaris is usually colorless, although it may be tinted a very fine green or bluish green. It is a very active organism, moving swiftly by means of numerous cilia which project from every part of its surface, save in the immediate vicinity of the head. In the largest specimens these cilia are easily seen, but in those of average size it is necessary to use a stain.
Loeffler's solution will stain both the ectosarc and the cilia, when the latter may be seen in rapid motion.

In addition to these, a great variety of other organisms are found, some of them in large quantities at certain seasons of the year. A few of these are important because of the part they play in the production of disease, while most of them are probably without any pathological significance.

The *Amoeba ciliaria* is an important morbilic agent because:

(a) It may become a host for parasites.
(b) While a host, it may itself become a parasite.
(c) It possesses a wonderful power to penetrate tissue.

That it may harbor parasites is shown by the following: A litre of water was drawn from the hydrant. Practically all the motile organisms it contained were collected into a few drops. In one drop placed upon the slide was a very large amoeba. The cilia were numerous and were very plainly to be seen without the use of a stain, as its movements were sluggish. It was about twice the size of the average amoeba and measured approximately sixty micromillimetres in length and thirty micromillimetres in width, being elliptical in form. Cilia projected from the entire surface of the ectosarc, save a small area about the head where none could be seen. By racking the microscope tube down upon the cover slip the ectosarc was easily broken, and when racked up again it was seen that at the point where the ectosarc had burst a bacillus had escaped. This was followed by another and another, until quite a number had made their exit from the ectosarc.

This bacillus was short and comparatively thick, had a very lustrous body, and was exceedingly active. Any one familiar with the appearance of the typhoid-fever germ would say at once it was that bacillus. It bore as close a resemblance to the typhoid-fever germ as one typhoid-fever bacillus could bear to another. They would disappear from the field so quickly that it was impossible to follow their movements. Some would reappear only to dart quickly across the microscopic field. Their movements presented that peculiar appearance due to a change in the angle of refraction, and which is seen to the best advantage in the movements in the typhoid-fever bacillus through water. The typhoid bacillus, or another that can not be distinguished from it morphologically, is not the only germ that is found as a parasite in the amoeba. In this same individual were a large number of monads that floated down in the stream that poured from the rent in the ectosarc. Their movements were very similar to those of the monads seen in the blood of persons suffering from malarial infection. Cocci and diplococci were also to be seen. In addition to the bacilli, the monads, and the cocci, were the large number of ovules of the amoeba. All these, together with the contained fluid, had swelled the ectosarc almost to bursting, and instead of the easy, rapid motion characteristic of the adult amoeba, there were the slow, labored movements of this disease-infected organism. The ectosarc with its cilia quickly disappeared, so that in a very short time nothing but what it had inclosed could be detected at the former site of the amoeba.

Many times since, the same phenomena have been witnessed on smaller amoebae, so large a one being rarely encountered. In these smaller amoebae it is difficult to burst the ectosarc by mechanical pressure, and chemicals are resorted to for this purpose. In this way the contents are easily studied, and, while a very large number of observations show the amoeba as it exists in drinking water to be as a rule free from these lower organisms, it is often found to be infected with cocci, monads, and bacilli whose presence distends the ectosarc, inhibits the movements, and finally results in the death of the host.

A distinction is made between coccus and monad, the first changing its shape only to form pairs or groups or chains of bodies morphologically similar to the parent, the second being only one of a number of forms of some higher organism assumed successively in its cycle of existence. "The name of monad has been commonly applied to minute free or fixed, rounded or oval bodies, provided with one or more long cilia, and usually provided with a nucleus and a contractile vacuole. Some are locomotive conditions of indubitable plants, others are embryonic conditions of as indubitable animals, yet others are embryonic forms of organisms which appear to be as much animals as plants, and of others it is impossible to say whether they should be regarded as animals or plants." (Huxley.)

As the cocci and some of the monads—higher organisms in the embryonic form—look so much alike, it is sometimes difficult to distinguish the one from the other. Where no diplococci are present to mark the distinction, it may be necessary to cultivate the germ and watch its development. After the death of the host, these organisms, whether coccus or monad, multiply very rapidly, the ectosarc bursts and the germs are set free. The resting form of the amoeba, removed from cold water into hay infusion at room temperature, is the most favorable for study. This is most conveniently done during the winter months. The amoebae attain a large size and show the ovules plainly within. For the first few days they are very vigorous and feed upon the saprophytes that chance to be present. With the lapse of time, as the alkalinity of the fluid deepens, the latter gain the upper hand, and in the course of a month nearly all the amoeba, little and big, are dead, many of them filled with parasites, some of them bursting, setting the latter free. These parasites are usually cocci, monads, and bacilli, often the *Bacillus subtilis*.

Parasitism among these infusoria is very common. The cocci and the monads, from their small size and wide distribution, are the most frequent victims. It
would seem that these small bodies form a large portion of the food of many of these water organisms, but that after the death of the latter these cocci multiply so rapidly that en masse they present the dull grayish appearance referred to above, when the clusters of cocci must number millions of individuals. It is no uncommon sight to see a dead larva, amoeba, Epistylis nutans, and a host of other organisms teeming with these micrococi.

That this amoeba may become a parasite is proved by the following: Some flowers gathered from the fields, with their stems left long, were put into a vase containing hydrant water. In a course of a week large numbers of the Amoeba ciliaria had developed in this fluid. Numerous larvae found their way into the vase, and were with the amoebae removed from time to time by means of a capillary pipette to a glass slide. The amoebae were fine specimens and were exceedingly active. Most of the larvae were dead; a few were alive. In one large, dead larva over a score of amoebae were found actively swimming to and fro just within the external capsule of the larva and upon its ventral surface. Here they had made for themselves a wide channel in which they moved about with great freedom, the channel extending for almost the entire length of the larva along its ventral surface. The amoebae were very active in their endeavors to effect an escape, but, although under observation for over an hour, not one succeeded in doing so. Of the scores of amoebae that hovered about the larva on the outside, not one effected an entrance, although they endeavored to do so.

Another instance going to show that this amoeba may become a parasite within other higher water organisms is the following: The organic matter in a litre of hydrant water was concentrated into a few drops in the usual way. In one of these drops, placed between a slide and cover slip, was found a Microcodon clavus. Its movements were so rapid that it was impossible to keep it at all times in sight. It was, however, possible to keep it under observation for the greater part of the time. It was perhaps twenty minutes after it had first been sighted, and while in full career across the microscopical field, that it came suddenly to a full stop. From the manner in which the cilia were extended, it was at once seen to be dead. Now a most curious thing was observed. While about half its mass was perfectly motionless, dead in fact, the other half, which was in the form of a sphere, was moving slowly and evenly round in a circle within the dead mass. The organism seemed to be dying by integral parts. The revolving round body within, moving in the line of a perfect circle, brushed throughout its entire periphery against the mass of dead matter without. Within the living sphere were granules in constant motion. Gradually the sphere assumed an elliptical form, the smaller end of the ellipse cleared of granules, and, as it continued to circle round and round, would at intervals be pushed out-ward as if to penetrate the mass of dead matter which formed a barrier that effectually shut in the mass of living matter.

This was kept up for almost half an hour. Suddenly an opening was forced through the wall of dead matter and there passed through it and out into the clear surrounding field a living amoeba! It moved about with all the ease and freedom characteristic of a perfect amoeba, having apparently suffered no injury from its confined position within a host little larger than itself and which had carried it with rapidity through the water on the microscopic field until the microcodon suddenly stopped, dead. The amoeba had left it lying upon the field a mass of disorganized matter. Here it had entered its host while the latter was yet alive. Although this is not proved in the case of the larva, yet it is almost certain that the score or more of amoebae had entered their host while the latter was still alive and had made their way from the alimentary canal outward, to where they were found, having been stopped only when they had reached the external integument of the larva.

The elasticity of the ectosarc enables the amoeba to adapt itself to the form of the cavity in which it may happen to be compressed, no matter how irregular the cavity's walls. If it chances to be surrounded by organic matter with a narrow channel leading from its place of imprisonment, it will force its way through the channel. The head precedes, and, as the body molds itself to the narrow, tortuous passage, it is drawn out to the required length. All parts of the endosarc are constantly shifted all the while, as is seen from the continuous movement of the granules. When the obstruction has been passed, the amoeba immediately resumes its usual elliptical form.

The degree of attenuation the ectosarc is capable of sustaining without bursting was shown by the following: The organic matter in a litre of hydrant water was collected and mounted in the usual way. An amoeba was shifted to the centre of the field, and the tube quickly backed down for the purpose of bursting the ectosarc. So much pressure was used that the slide bent slightly under it. The tube was immediately backed up again for the purpose of noting what had been contained within the ectosarc. Two large-sized ovules and a few granules were all that could be seen. Then a surprising thing occurred. After a considerable time some granules were seen to shift their position slightly.

After a while this was repeated, when it was seen the ectosarc was still intact, but spread out over an area many times that originally covered by the amoeba. When it is remembered that two superimposed capsular layers that had been the ectosarc of so small an organism were spread out over so large an area, it is seen how remarkable was the degree of attenuation of the ectosarc. The contractions were repeated more and more frequently. During the intervals between the con-
The floating writing pose the some strip forms months numerous •double), been the to individual substance. In cocci, anaerobes. paraffin. upon live. site a slide a This growth spec. a Navicular, diplococci, and the amoeba shows them to be aerobic. It is easily shown that they are, at least some of them, facultative anaerobes.

A drop or two of hydrant water was placed between a slide and cover slip. The edges were sealed with paraffin. This specimen was found to contain numerous cocci, numbers of monads, some amoeba still retaining the filament, several fragillaria, a few bacillaria, two small navicule, three Asterionella formosa (one double), and one Vorticella convallaria, the body severed from its stem, but lying in close proximity to it.

This specimen was examined from time to time and the growth of the various organisms noted. The cocci multiplied rapidly, forming clusters of a circular form. In a few months it was seen that in some instances the substance uniting a diplococci would persist, and a number of diplocooci would be joined to each other, forming a chain containing from four to six up to ten individual cocci, the chain appearing like one of streptococi. The rounded clusters bore a marked resemblance to the staphylococcus as it is seen in nutrient media. Seven months after this specimen had been mounted, numerous cocci were alive and as active as ever, showing this organism to be a facultative anaerobe, having been shut in from atmospheric air for that length of time.

The amoeba present were in that stage of development when they still retained the filament. Seven months afterward they were found to be as active as on the day when they were mounted, although the motile forms were fewer in number. Some of them developed a very fine tint of red, blue, or green, although this specimen had been all these months shut in from light in a closely fitting box, except when removed for the purpose of examination.

This specimen was mounted June 1, 1898. At this writing (March 9, 1899) the only water left is a narrow strip near the edge of the cover glass, extending for some distance along the periphery, but not reaching beyond that quadrant. In this narrow strip are now a fragillaria, numerous bacillii, some monads, and several groups of ovules of the **Amoeba ciliaria**. These last are very fine specimens of the amoeba as it is seen after the ectosarc has burst and before the ovules are dispersed. They show that as an anaerobe the amoeba may complete its cycle of existence. They also show that as an anaerobe it multiplies rapidly. It is therefore a true facultative anaerobe:

A principal feature of this specimen at this time is the presence of the baecilli. No baecilli were to be seen as late as December 22d, nor for any day of the two hundred and five days since June 1st. The question as to what they are? An attempt will be made to answer this later on.

The nutrient medium greatly modifies their form. If adult amoebe are put into water slightly aeridified with acetic acid, then neutralized or made slightly alkaline with sodium hydrate, in from a month to two months no adult amoeba will be found. In their place are the young, not of an elliptical but of a much elongated form, the filament not having disappeared but grown into a powerful probosces one third as large at its proximal end as is the body of the amoeba in its greatest diameter, a small cilium having developed at the opposite extremity. These are its locomotive and phr. sile organs, a floating body being quickly seized, the cilia being approximated first on one side, then on the other, with great dexterity. This is the form of the **Amoeba ciliaria** that is found in dysentery.

If adult amoebe are put into a fresh infusion of potato, all motile forms will after a time, as the alkalinity of the infusion deepens, disappear. In their place will be found the ovules. These are of uniform size, of the dimensions and appearance of pus corpuscles, and would be liable to be mistaken for such if found in the urine. A careful inspection will show the very well defined and regular outline of the ovule membrane, the sphere of young amoebe within, and the clear interior free from granules between the two.

**The Amoeba in Disease.**—This organism is found in hydrant water in spring and in autumn, in summer and in winter, in the hot summer months of July and August as well as in the cold winter months of December and January.

It is found every day in the year, and it is not a high estimate to say that the man who drinks a litre of hydrant water for each twenty-four hours, swallows on an average not less than a score of amoebe in various stages of development every day. This statement is based upon a series of observations made almost every day for a year upon the organic matter collected daily from a litre of hydrant water.

In a number of acute infectious diseases, this amoeba has been found in the blood, in the sputum, in the watery evacuations from the alimentary canal, and in the urine. Among these diseases are typhoid fever and purpura hemorrhagica.

**Typhoid Fever.**—In a recent case of typhoid fever,
the amoeba in its resting form was found in the blood
and in the urine. Small round bodies, ovules of the
amoeba, were found in the blood, mingled with the
corpuscles. A more significant find, however, was a
full-sized amoeba, in its resting stage, with well-defined
capsule, an elliptical body of ovules within, and a clear
space between the two. It presented the appearance of
the resting amoeba as it is seen in very cold water,
except that instead of the highly refractive nucleus,
there was the nucleus of developing amoeba, the
individuals of which could already be made out. This
was found in a drop of blood removed from the ear. No
bacilli were found in this body.

In a drop of blood removed from a rose spot some
ovules were found and a few bacilli, but it is not certain
they were the typhoid-fever bacilli, though they bore
a resemblance to them.

From a papule on the back, a drop of blood was re-
moved. This was especially rich in "white blood-corp-
uses." One clump was found that looked as if the
corpuscles had been confined within a capsule and the
latter had burst without their arrangement having been
disturbed.

Amoebae with capsule intact were found in the
urine. Most of them, when the capsule was dissolved,
were found not to contain bacilli, but a few contained
them. The question is, Were they the typhoid-fever bacillus? In size, form, and activity they closely re-
sembled it, but they lacked the highly refractive prop-
ties characteristic of that bacillus. It is probable that
transitional forms are found free in water, but that the
typical bacillus is seen only shortly after it has made
its escape from its host, it being unable to long retain
its capsule free in water.

It probably acquires its peculiar refractive prop-
ties while resident within its host, and then only after
it has been present for a considerable time. It is pos-
sible the typhoid germ enters upon its existence as a
parasite while it is yet a spore. "It is almost uni-
versally believed that, as a rule, typhoid bacilli do not have
any permanent, independent existence outside the
human body." (Strümpell.)

The bacilli present in the specimen mounted June
1st possessed a highly refractive body and were first
seen over nine months after air and light had been
excluded.

Although previous to the attack the patient had en-
joyed robust health, a remarkable feature of the case
was the very large number of white blood-corpuscles
present. It is just possible these bodies were not all
white blood-corpuscles.

The clinical symptoms were those of typhoid fever.
There was the typical temperature curve with its morn-
ing remissions and evening exacerbations, and a maxi-
mum temperature of 105° F. There was excitement
bordering on delirium. There was gurgling in the right
iliac region with tenderness, enlarged spleen, and epis-

taxis. The stools were characteristic, thin, yellowish,
and very offensive. A number of rose spots were to be
seen. The attack lasted three weeks, at the end of
which time there was great emaciation. With recovery
came a voracious appetite.

In the case of a young man who died from typhoid
fever, ovules of the amoeba were found in abundance,
over a year afterward, in a specimen of the urine that
had been preserved. It was strongly alkaline. No
other organisms could be found.

(To be concluded.)

TYPHO-MALARIAL FEVER.*

By CHARLES R. GRANDY, M.D.,
NORFOLK, VA.

I have chosen for discussion to-night a subject
which has often been debated, and which may appear
to some of you rather hackneyed. I refer to the so-
called "typho-malarial fever." It is a subject on which
all of us do not agree, and on which much has been
written in the past year. It especially concerns all
physicians practising in this climate, as the first
American cases described were contracted in Virginia.
As there seems to be a marked difference between the
diseases described in Europe and in America as typho-
malarial fever, I will confine myself to a discussion of
the term as used in this country, along with some refer-
ce to the most recent reports on the subject.

Although a combination of typhoid and malarial fe-
vers seems to have been described in Europe as early
as the beginning of this century, the term was first in-
roduced into America at the time of our civil war,
when it was used to cover a class of fevers from which
the Army of the Potomac suffered a very great deal.
These fevers were most marked in the Peninsular cam-
aign and were likewise designated Chickahominy fever.
The term typho-malarial fever was introduced into medical literature by Woodward in his work on
Camp Diseases (1863).

Woodward's diagnosis was eagerly accepted by the
physicians of the time, and indeed seems to have been
undisputed for twenty years. Flint, for instance, says
in 1866: "Typho-malarial fever is caused by the com-
bined action of malaria and the special cause of typhoid
fever, remittent and typhoid fevers being thus associ-
ated." In Reynolds's System of Medicine (1872) Har-
ley says: "We unhesitatingly conclude that enteric fever
is often a part of intermittent fever, and the converse." Har-
ley, an Englishman, does not claim to have seen
cases of this fever, but makes the foregoing statement
almost entirely on Woodward's authority.

We must remember that the authors quoted wrote
before Koch had made those discoveries which in rea-
lity laid the foundations of modern medicine, and that,

* Read before the Norfolk Medical Society, April 11, 1899.
having nothing more than the general symptoms of the patient to rely upon, they could not prove their assertions; nor, on the other hand, could their assertions be attacked with any chance of success. There were cases which differed from the typical forms of both typhoid and malarial fevers, yet resembled both in many respects; why not call them typho-malarial fever? Thus it remained until, in 1880, Eberth discovered the typhoid bacillus, and Laveran, in the same year, the Plasmodium malarium. These two discoveries formed the point upon which must rest the proof of the very existence of this disease. For if, as Flint says, “it is caused by the combined action of malaria and the special cause of typhoid fever,” we must find in autopsies performed on these cases both the typhoid bacillus and the active malarial plasmodium, together with the changes known to be produced by these two organisms when acting alone—i. e., the typhoidal ulcers and the malarial changes in the blood. Such a case has been, and still is being, diligently sought after, but no such case has yet been reported.

There soon arose a set of men who called for such proof before allowing the existence of typho-malarial fever; while its partisans replied: “If there is no such disease, what then causes these symptoms?” One single autopsy is enough to prove that this disease can exist. But until this positive proof is found no amount of conjecture, no amount of resemblance to the symptoms of the two diseases (malarial and typhoid fevers), can establish its existence. On the other hand, the question propounded by those who maintain that such a disease exists must be answered, its symptoms must be explained, and it must be shown that they can be caused without “the combined action of malaria and the special cause of typhoid fever.”

Before attempting this, let us see how such a confusion arose. Let us look at typhoid and malarial fevers separately. These two diseases, while absolutely distinct when running typical courses, so often vary and so often approach each other in their symptoms that it is at times extremely difficult to make a diagnosis between them. This applies especially to typhoid fever, which has a different form for almost every locality, and which departs most from its recognized form in those very localities in which malarial fever exists. So marked is this, that until quite recently it was denied that typhoid existed in the tropics, while it is now acknowledged to be very common there, only it departs from the typical course laid down for it in the textbooks. Such an atypical typhoid, without the rash, without delirium, with a continued, though not a typical fever curve, and perhaps with some chills and rises of temperature toward the end of its course, can well be, and often is, mistaken for malarial fever. On the other hand, malarial fever, especially the kind caused by the aëtivo-autumnal parasite, which usually is of the remittent or continued type, can be accompanied by diarrhea, vomiting, a dry tongue, and perhaps by delirium. Thus it closely resembles typhoid fever. Can, then, our predecessors, without a full knowledge of the pathology of the two diseases and with nothing but symptoms to guide them, be blamed for shirking the diagnosis, and putting all such forms under one head with the convenient term typho-malarial fever to designate them all? But what applied to physicians twenty years ago does not apply to us now. When we now are in doubt about a fever’s being malarial or not, we search for the plasmodia, which can always be found in the blood of patients with an active malarial fever, though at times several examinations must be made before they are discovered. In typhoid fever, too, we have a valuable aid in the Widal reaction, the chief objection to this reaction being that it cannot be obtained till after the first week of the fever. These two tests should always be tried in suspicious cases, and without them no reported case of typho-malarial fever is of value.

Most cases formerly called typho-malarial fever seem to have been nothing more or less than atypical cases of typhoid fever, all cases of this disease which in their course showed an irregular temperature curve or chills being classed as a mixed infection. But that this is not necessarily the case is shown by the fact that typhoid fever, occurring in countries where no malarial fever is found, very often has these intermittent chills toward the latter part of its course. I may well quote Thayer on this subject. “It is very important to recognize the fact that intermittent fever with chills is not an infrequent symptom in typhoid fever, particularly during defervescence and convalescence. These intermittent chills, however, in the great majority of cases have no connection with malarial fever. They are due to secondary infections or to auto-intoxications of a nature as yet unknown.” There are also cases of malarial fever which run a continued course, being produced by either two or more sets of the tertian parasite or by the aëtivo-autumnal parasites, which do not develop in the same regular way as the tertian. These cases are often called typho-malarial fever, though not so often as the atypical typhoids. They respond to treatment by quinine, often first going into intermittent fever, one set of parasites being killed before the other. They, of course, have no relation to typhoid fever.

On the other hand, we know that the Plasmodium malariae may remain for a long time dormant in the blood, producing no symptoms whatever till the general health of the individual is reduced by some other cause. This is often observed in people who move from a malarious district into the mountains. At home they had not suffered from malarial fever, but the change of climate and fare is enough to bring on an attack. Now, may not typhoid fever in such a subject, by causing loss of bodily resistance, allow the hitherto dormant plas-
modia to develop? If typhoid fever acts in this way, we would be most apt to get malarial symptoms toward the end of the disease, when the patient is convalescent; as time must be allowed for the reduction of the general vigor of the patient, and after that time for the organisms to multiply sufficiently to produce the fever. Such an attack, however, could not be looked upon as a mixed infection, the two diseases being entirely distinct, but as simply a coincidence, the chief and real disease being typhoid fever. Again, if at the beginning of an attack of typhoid fever malarial paroxysms occur, and if the symptoms and the organisms are made to disappear by the use of quinine while the typhoid runs its usual course, we have two synchronous diseases with no direct connection. The two diseases would be no more dependent upon each other than gonorrhoea and phthisis in the same subject, and have no more right to be classed as one disease.

As we mentioned before, the term typho-malarial fever was introduced to explain the disease which caused such havoc during the civil war. Thus the fevers which attacked our armies during the Spanish war have furnished material for a further thorough investigation on this subject. If there is such a disease, it would certainly have appeared among the numerous fever cases in the various camps and hospitals. Here it was searched for by some of the best men in the country, and their reports seem to me to be almost conclusive.

The most interesting of these reports seems to be that of James Ewing, who made the blood examinations at Camp Wikoff. Here he had the soldiers who had been through the Santiago campaign and who presented malarial fever in its worst form, as well as typhoid fever. Altogether he examined eight hundred cases of malarial fever. I think his report is valuable enough to quote from at length.

"Forty cases were reported as cases of typhoid fever in anemic and malarious subjects. In some of these cases the disease began with one or more short rigors repeated on successive days, after which the disease progressed with the usual symptoms of typhoid fever. In one case the usual history of Cuban malaria was interrupted by the development of typhoid fever with all essential symptoms. Plasmodia could not be found in the blood, but in the second week of convalescence tertian chills and fever supervened and tertian parasites were found in the blood. Other cases illustrated the same behavior of the malarial infection during the course of typhoid fever. Two fatal cases of typhoid fever in malarious subjects came to autopsy. No parasites could be found in the blood during life, but in smears from the spleen and marrow diligent search revealed the presence of a few rings and crescents, with much old malarial pigment." The blood from a hundred and fifty-nine cases of typhoid fever with intermittent character of fever was examined. "In no case of undoubted and established typhoid fever were malarial parasites found in the blood in connection with any of those sudden rises of temperature, but only at the onset of the disease or during convalescence.

"On the other hand, many patients whose blood contained numerous parasites were seen in the 'typho-
state,' but there were always some essential symptoms lacking to confirm the diagnosis of typhoid fever, while the subsequent course of the disease, when observed, demonstrated the purely malarial character of the fever.

"In the cases which came to autopsy there was never any doubt of the disease. It was either typhoid fever or malaria, but never both, although microscopic evidence of dormant malarial infection was found in at least two cases of typhoid fever. In short, in spite of painstaking effort, the attempt to find a case of typhoid fever and active malaria progressing simultaneously was unsuccessful."

Ewing's report is corroborated by the observations of other physicians. Thus in the reports on typhoid fever among the soldiers treated in the Philadelphia hospitals, J. C. Wilson states that malarial organisms were found in the blood of typhoid patients, but malarial symptoms did not appear until convalescence. They were then cured by the use of quinine. Tyson found the plasmodia in the blood of two cases convalescing from typhoid fever. Alfred Stengle likewise found the tertian parasite in two cases during convalescence. J. M. Anders examined two hundred and sixty-six patients, but found no combination between typhoid and malarial fevers, though the plasmodium was diligently sought for. Da Costa found the tertian malarial organism in the blood of ten cases of typhoid fever; the malarial symptoms seem to have developed during convalescence.

William H. Thomson, speaking before the New York County Medical Society, said: "The cases of mixed infection with typhoid and malaria ran the usual course of typhoid fever, and were treated without quinine. Two of the patients, after being fairly convalescent from typhoid fever, had an attack of chills and fevers, which soon yielded to treatment. During these attacks the plasmodium had reappeared in the blood."

Gilman Thompson reported seventeen cases of mixed infection. The plasmodium remained quiescent during the course of the typhoid fever or until a few days after the convalescence had begun; the effects of the malarial poison then became manifest. (Some years ago the same authority reported one case in which a malarial chill occurred during the third week of the typhoid fever. This was controlled by quinine, and the typhoid ran its usual course.)

George Dock, in a recent paper on Typho-malarial Fever, so called, says: "I have examined many suspected cases, many of them pronounced typho-malarial fever by physicians of high standing, but so far
have failed to find a case of mixed typhoid and malarial infection. A number of autopsies were made, but without revealing latent malaria. This experience was obtained partly in Texas, partly in Michigan, and more recently in army hospitals at Chickamauga, Knoxville, and Camp Meade, Pennsylvania."

Lyon, in an article entitled Combined Typhoid and Malarial Infection, collects cases reported in this country and abroad, as well as reporting a case of his own. This case shows the malarial symptoms at the beginning and during the convalescence of the typhoid and not during the course of the latter disease. It does not differ from the other cases reported, though this author, basing his conclusions more on possibilities than reported facts, draws rather different deductions from the others.

I will content myself with these very recent statistics, even omitting such men as Osler and Thayer, with whose works you are all well acquainted. I trust you will excuse me if I add a short report on two cases which came under my observation last summer.

**Case I.**—The author saw this patient in consultation with Dr. E. E. Field, to whom he is indebted for the following history:

Patient, a soldier in the infantry, was taken with a chill while working in the trenches around Santiago. Was from his own accounts extremely ill in Cuba, but recovered sufficiently to return to this country. He did not stay in Camp Wadsworth, but after staying a few days in New York city came relatives in Norfolk. He arrived in poor condition and was attacked by intermittent fever on August 27th. There were the chill, fever (temperature reaching 105° F.), and sweating. On the following day no fever. Spleen large and tender. The blood showed pigmented tertian malarial organisms both within and without the red corpuscles. This attack responded to treatment by quinine.

On September 13th I was called again to see patient, who two days previously, after very imprudent eating, had been taken with a chill, followed by fever, sick stomach, diarrhea, and pain in the abdomen. The fever continued with daily exacerbations for several days; he had some delirium and a dry, coated tongue. At this time a blood examination showed two sets of tertian parasites. Quinine was given, but the fever continued, although it now showed a more regular curve. On September 29th a positive Widal reaction was obtained. The fever then ran the course of typical typhoid fever, the rose spots appearing. On October 19th the fever had disappeared. On October 23d patient again had a chill, followed by fever and sweat. The malarial organisms were again found in the blood. Quinine was administered and the patient convalesced without return of fever. The malarial organisms here were active at the beginning of the fever, remained dormant during its height, and again showed activity during convalescence.

**Case II.**—This case, while not so marked as the one just reported, and not so carefully studied, is of especial interest because it was contracted in this section. The patient was not seen once by the author in consultation with Dr. Ruffin.

Four days before, the patient, a healthy young man, had had a slight chill, followed by fever; the next day there was a remission, but not a complete intermission. The fever then became very irregular, but did not in the first few days rise above 103° F. When seen by the author the patient was restless, complained of headache, bowels were constipated, the spleen was enlarged, his temperature 103° F. A blood examination showed pigmented tertian parasites within the red cells. The Widal reaction could not be obtained. Quinine was administered and the fever dropped, but not quite to normal. Afterward it rose gradually, and the patient developed a case of typhoid fever, from which he recovered without a return of the malarial symptoms. I am sorry to say that the Widal reaction was not tried later in the disease. In this case malarial and typhoid fever coexisted at the beginning of the latter disease. But the malarial fever was easily eliminated by the use of quinine, while the typhoid continued its course.

In summing up these reports we find that typhoid fever may occur in an individual who has already dormant malarial organisms in his blood; that these organisms produce symptoms either at the onset or during the convalescence of the typhoid fever; that they remain quiescent during the course of that disease (only one case to the contrary); that the early malarial symptoms may be checked by quinine without influencing the course of the typhoid fever; and consequently that the two diseases should no more be classed as a "mixed infection" than typhoid fever and measles occurring in the same person.

Before concluding, it would perhaps be well to look more narrowly at the term typho-malarial fever, and see what conditions would justify its use. These seem to be only three such conditions possible:

1. A Distinct Disease.—That is, one caused by an organism distinct from the malarial plasmodium and the typhoid bacillus. No one now maintains that such a disease exists.

2. A Mixed Infection.—Here the two diseases must be so intimately blended that they in reality form a new disease. No evidence of such a blending has yet been found, though thousands of cases have been examined.

3. As Two Coincident Diseases.—Here typhoid and malarial fevers simply coexist as two independent diseases. We have seen that this really does occur in some instances. But is this connection sufficient to justify a new name? The malarial symptoms under such circumstances occur either at the beginning or during the convalescence of the typhoid fever, but remain quiescent during the course of the latter disease. They are usually easily controlled by quinine, while the typhoid fever continues its usual course. In this connection, as Dock says, "there is no more reason to speak of a mixed infection than there would be in a simple case of pneumonia to speak of a mixed infection because streptococci were found in the mouth."

We have seen, on the other hand, that the term typho-malarial fever is used here in America to describe no fewer than three distinct conditions or diseases
which have certain points of resemblance. At least two of these uses must of necessity be incorrect. The great majority of such cases seem to be nothing more nor less than atypical typhoid fever, entirely without malarial complications—here the term is absolutely erroneous. The next group of cases is a continued form of malarial fever—here the term is equally erroneous. The third and much the smallest class may well be designated typhoid fever occurring in a malarious subject. Here the typhoid fever, the stronger disease, so conceals the malarial symptoms that they appear only at the beginning or at the end of the typhoid fever. While it would be incorrect to state that the symptoms of the two diseases could not occur at the same time, still the two diseases seldom if ever do run their courses in unison. When they occur in the same person they occur as two distinct diseases, each absolutely independent of the other, and they can not with any degree of accuracy be classed as one disease.

Besides the love of accuracy, which ought to be enough to deter physicians from using an incorrect term, other more practical considerations arise. If one diagnosticates a case to be typho-malarial fever, one is apt to continue the quinine treatment throughout the course of the disease. This in a case of uncomplicated typhoid fever will do no good, and perhaps much bodily harm to the patient. According to the best authorities, this treatment should not be continued more than three days without further evidence that malaria exists. Thayer, for instance, says: "There is no excuse for chinonizing an individual with continuous fever, who after three or four days shows no change of symptoms, while the blood is free from malarial parasites." Then the diagnosis of typho-malarial fever gives the laity an impression that they have to deal with a disease of milder character than typhoid fever, the term implying to them merely a variety of malarial fever. This is certainly not fair to the patient and his family. There seems indeed to be only one excuse for a physician's using the term in its ordinary sense—that is, when he himself, unable to make a diagnosis, wishes, in the slang of the day, to "hedge." No one would commend such a use of the term.

When malarial fever exists with typhoid, it is merely a complication, without intimate connection. One can be eliminated, while the other runs its uncomplicated course. Therefore we must conclude with Thayer that "there is no such disease as typho-malarial fever in the ordinary sense in which the term is used. The term is incorrect and misleading, and should be abandoned."

The St. Louis Medical Society.—At the last regular meeting, on Saturday evening, the 23d inst., Dr. H. C. Fairbrother read a paper on Syphilitic Meningitis, and Dr. Bransford Lewis exhibited genito-urinary pathological specimens.

### A Third Report Relating to The Heated-Blood Treatment of Croupous Pneumonia.

By Carl E. Elfstrom, M.D.

**Case VII.**—Girl, nine years of age.

**January 17th.**—Headache and fever. In the night, between the 17th and 18th, she had some epistaxis; on the 19th, severe bleeding from nose and mouth.

**20th.**—Consolidation of lower lobe on right side; no rales. Leech applied and the blood taken, diluted with salt solution, was heated to 140° F. during two hours; then injected subcutaneously at 4 P.M. The pulse was then very weak, 140; respiration, 54; temperature, 103.2° F.; urine gave slight reaction to albumin test. 9 P.M.: Patient apparently improved. Pulse full and soft, 120; temperature, 101.5° F.

**21st, 10 A.M.**—Temperature, 100° F. The respiratory murmurs weaker over lower lobe; signs of consolidation in the upper lobe. Pulse, 100—110. 4 P.M.: More severe epistaxis. Pulse, 100—110; temperature, 99.5° F.; respiration, 40. Cough loose, with mucopurulent expectoration. Pain entirely disappeared, even when coughing. Tongue clear at apex and edges. 9 P.M.: Very strong epistaxis. Pulse, 100—110; temperature, 97.6° F.

**22d, 9 A.M.**—Pulse, 100; temperature, 101.5° F. Subcrepitant rales: no albumin reaction.

**23d, 10 A.M.**—Temperature, 99.8° F.; pulse, 100. Subcrepitant rales. 9 P.M., temperature, 99.8° F.; pulse, 100.

**24th, 10 A.M.**—Temperature, 98.8° F.; pulse, 100. Rales. Patient looks well and strong.

**25th, 12 M.**—Temperature, 98.8° F.; pulse, 90. No albumin reaction. The disease apparently cured.

**Case VIII.**—Boy six years old. In May, 1898, had measles complicated with broncho-pneumonia; he was taken sick January 26, 1899, with acute croupous pneumonia.

**January 29th.**—Consolidation of right upper lobe. 9 P.M.: Temperature, 100.5° F.; pulse, 120; respiration, 48; no albumin in urine. Leech applied and the blood taken, diluted with salt solution, was heated to 110° F. during two hours; then injected subcutaneously at 9 P.M.

**30th, 10 A.M.**—Temperature, 101.2° F.; pulse, 120; respiration more turbulor; no albumin. 6 P.M.: Well-marked change for the better. Less dyspnea. Pulse, 100; temperature, 103° F. 11 P.M.: Twenty-six hours after injection, temperature, 99.9° F.; pulse, 100. Subcrepitant rales.

**31st, 10 A.M.**—Pulse, 98; temperature, 100.2° F.; numerous subcrepitant rales. 9 P.M.: Temperature, 102.8° F. Consolidation seemed to have increased. Rales less numerous.

**February 1st.**—Temperature, 98° F.; pulse, 72. Numerous subcrepitant rales. Disease apparently cured.

A curious fact in this case was that the disease, which seemed past crisis in the evening of the 30th, that is, about twenty-four hours after the injection, took a fresh start in the evening of the 31st. only to be subdued for good the same night.

* For Cases I to VI see New York Medical Journal, August 27 and October 15, 1898.
Case IX.—Man, aged thirty-two years. He became ill with chills on the morning of April 3d.
April 4th, 12 m.—Congestion of the whole left lung and lower lobe of the right. Cyanosis. Pulse weak, 120; respiration, 39; temperature, 103.3° F. Lecith applied and the blood taken, diluted with salt solution, was heated to 140° F. during two hours; then injected subcutaneously at 4 p.m. At 9 p.m. same day, no change. Temperature, 103.7° F.
5th, 12 m. Consolidation of the lower lobes on both sides. Auscultation still showed a certain amount of congestion over the left upper lobe. Subcrepitant rales over the consolidated parts. Respiration, 20; pulse, 120, stronger; temperature, 103.5° F.; cyanosis disappeared. The change took place about midnight, eight hours after the injection. At 9 p.m., same day, pulse, 110; temperature, 102.8° F.
6th, 12 m.—Pulse, 110; temperature, 102° F.; some albumin. 9 p.m., temperature, 100.5° F.

On the 7th, 12 m.—Beginning consolidation of the left upper lobe. Temperature, 101.2° F. At 9 p.m., pulse, 130; temperature, 103.2° F.; cyanosis commencing.
8th, 9 a.m.—Left upper lobe fully consolidated. Marked cyanosis; respiration, 40; pulse, 150. Condition apparently alarming. Decided to give a second injection. A leech was applied and the blood treated by heating, as before, and injected at 1 p.m. Temperature then 103.4° F. At 9 p.m. slight change for the better. Temperature, 103.2° F.
9th, 12 m.—Subcrepitant rales over the left upper lobe. Respiration, 20; cyanosis disappeared; pulse, 110, strong; temperature, 101.2° F. At 9 p.m., temperature, 100.6° F.
10th, 12 m.—Temperature, 99° F.; pulse, 92.
11th, 12 m.—Temperature, 99° F.; pulse, 90. Albumin disappeared. Normal convalescence.

I wish to draw attention to the large portion of the lungs involved in this case, with the appearance of cyanosis as early as twenty-four hours after the attack, and the promptness with which the fever and the alarming signs were subdued after each injection.

This case is the only one in which I gave two injections, and, judging from this, it seems that Case VIII especially would have profited by a second injection.

Of my nine cases reported, two died. As these latter already before the injections gave unmistakable signs of meningitis, I protest against these two cases being counted (as has been done) in calculating the percentage of cure, which in reality, up to the present, has been one hundred per cent. In each of these two cases the injection was made only to ascertain its action on the lungs, without any intention to cure.

Therapeutical Notes.

Pills for the Headache of Neurasthenics.—The Riforma medica for July 24th gives the following formula:

1. R Zinc phosphide .............. 0.23 grain; Reduced iron .............. 3 grains; Extract of nux vomica ....... 1.8 grain.

2. M. Divide into eight pills. Two or three to be taken daily.

R Zinc valerianate, Iron sulphate, Extract of rhubarb, Salicylic acid
Asafetida,

M. Divide into twenty pills. One to be taken three times a day.

A Powder for Condylomata.—Riforma medica for July 17th gives the following:

R Calomel .................. 30 parts;
Boric acid .................. 15 "
Salicylic acid .............. 5 "

M.
The condylomata to be powdered therewith two or three times a day.

Raw Meat as an Aphrodisiac.—Dr. P. C. Remondino (Pacific Medical Journal, September), in Some Observations on the History, Psychology, and Therapeutics of Impotence, says that he has found a raw-meat diet highly beneficial in some cases of anaphrodisia, especially when occurring in one of a timid or anemic nature.

A Hypnotic.—Dr. F. Marz (Province medicale, September 3d) gives the following combination:

R Trional .................. 15 grains;
Powdered codeine ........... ½ grain.
For one powder. To be taken at bedtime.

For Flatulence.—The Union medicale du Canada for September gives the following:

R Beta-napthol .............. 2 grains;
Poplar charcoal ............. 8 "
The powder should be taken immediately after meals to avoid dyspeptic fermentation.

A Mixture for Cardiac Dyspnoea.—The Riforma medica for July 29th credits the following formula to G. Sée:

R Chloral hydrate .......... 2 to 4 parts;
Potassium iodide .......... 1 to 2 "
Julep ...................... 120 "
M. S.: A tea-spoonful every hour.
A MEDICAL STRIKE.

It is abhorrent that trade unionism in any form should have found shelter within the medical profession, but it seems to have come as a matter of necessity to some of our English brethren. The Lancet, in its issue for August 26th, publishes its special commissioner’s account of certain disagreements between the pit-men of the Wigan and District Miners’ Permanent Relief Society and the Colliery Surgeons’ Association which have culminated in what amounts to a strike on the part of the surgeons composing the association. The miners, it appears, have recently been deprived of their employers’ contribution to their accident relief fund, by reason of legislation making it no longer to the employers’ interest to contribute. It is on this account that they have organized their society, and like societies have been formed in connection with every colliery. They are spoken of as accident clubs, and their object is to provide medical attendance for miners who may be injured in the performance of their work. Each club, says our contemporary editorially, is supported by weekly contributions from the men, and its affairs are managed by a board. Out of the funds, a sum amounting to about sixty-two and a half cents annually for each member is set apart for medical fees. The board appoints as many surgeons as it requires to attend to accident cases, and at the end of the year the entire sum is divided equally among those attached to each pit. In case of accident it is the nearest surgeon who is almost always summoned, so that a surgeon living near the pit has to do the bulk of the work, while his fellow-surgeons get each as much remuneration as is allowed to him. This inequality of payment is the doctors’ grievance. They ask to be paid by the case, at the rate of fifteen shillings a year.

It is for this that the surgeons have been on strike, so to speak, since some time in July; that is to say, they have resolved not to attend any member of the relief society for accident on any terms, unless some satisfactory arrangement is made. In the mean time the society has endeavored to import surgeons who will accede to their terms, payment of about sixty-two and a half cents per annum for each man, but has succeeded in only one instance. Much as we deprecate trade unionism, we join our contemporary in the hope that that one imported surgeon “will, on further deliberation, join the rest of his professional brethren in attempting to right a grievous wrong.”

THE QUESTION OF OUR DANGER FROM THE ORIENTAL PLAGUE.

Appletons’ Popular Science Monthly, in its September number, has done what we look upon as a distinct service to the public by publishing an article by Professor Victor C. Vaughan, of the University of Michigan, entitled Are We in Danger from the Plague? It is because Professor Vaughan’s conclusion is so reassuring, and because the magazine in which it is expressed is so generally recognized as furnishing its readers with nothing on such questions that is not as near authoritative as human opinions concerning the future may be, that we make this statement. The recklessness and mendacity of certain newspapers may arouse anxiety, but the people will always listen to the sober teaching of the experienced observer.

Professor Vaughan starts with a sketch of the outbreak of the present visitation of the plague in Bombay and its spread over practically the greater part of western British India, and describes again the notorious neglect of the most obvious sanitary measures among the native populations of India, alluding to the extraordinary difficulties that beset official sanitation in that country owing to differences of caste and to religious prejudices. From these considerations, together with the practical failure thus far of all forms of curative serum and the great probability that only the intelligent will avail themselves of Haffkine’s preventive inoculation, the author is inclined to think that the disease will prevail in India until it is exhausted by lack of susceptible material to feed upon. Will it find its way to Europe? It would not be surprising, he thinks, if it should reach Constantinople. Thence its spread seems reasonably sure of prevention by carrying out the provisions of the Venice Congress and by the measures that the various European governments, acting individually, are certain to take. At the same time, he questions the sufficiency of relying on the assumption that the period of ten days covers the incubation of the disease, and he gives instances that appear to sustain his objection.

If the plague is to reach the United States, it will, he thinks, be by way of the Pacific coast, proceeding from Hongkong to Manila and thence to our own
shores. But the voyage from Manila to San Francisco is so long that infection on a vessel making the run would be almost certain to manifest itself before California was reached, and, the presence of the disease being known, thorough inspection and disinfection would keep it out of the country. All transports and other vessels plying between Manila and the United States, says Professor Vaughan, should be provided with proper disinfecting apparatus. The government, he adds, should supply the Marine-Hospital Service with every medical equipment, and if this is done, he declares, the plague can enter America only by reason of incompetency in that service—an incompetency, we may say, not at all likely to occur. He closes by pointing out that careful watching of our intercourse with Japan must also be carried out, for that nation controls Formosa, where the plague is now widely distributed.

BILE AS A CORRECTIVE OF THYREOID OVER-ACTIVITY.

The use of bile as a medicine, in the familiar form of inspissated ox gall, is no novelty, but recently Dr. C. M. Allan, of Longton, England (Lancet, August 26th), has given what he considers good reasons for looking upon the secretion of the liver as having other functions than those of a digestive, a laxative, and an intestinal antiseptic, and as a remedy capable, when administered by the mouth or subcutaneously or applied to the wounded thyreoid gland, of counteracting overactivity on the part of that gland and of correcting the action of its secretion when it gets access to the tissues in abnormal abundance. He goes further than Dr. Adami, of Montreal, whose view that "one of the functions of the liver is to arrest the further passage of these [the colon and other] baelli into the general circulation, and to destroy them through the agency of the specific cells of the organ," he cites. These suggestions of Dr. Allan's, though modestly and tentatively offered and not purporting to rest on anything like a demonstration, seem to us far more than speculative. His article is a long one, and we can not do more here than to indicate a few of its notable points; it will well repay reading in extenso.

Dr. Allan tells how he was led to the idea that the bile was in some degree a corrugent of the internal secretion of the thyreoid, and he then relates the results of his use of the biliary secretion in the case of a middle-aged woman who, having for ten years been the subject of occasional attacks of exophthalmic goitre, although her thyreoid gland was not at any time sufficiently enlarged to be noticeable except on examination, suffered with a very pronounced attack occurring as a complication of influenza. There was a striking deficiency of bile in the dejecta, and the opportunity seemed a good one for testing the efficacy of bile as a remedy for exophthalmia and its accompanying symptoms. It was given by the mouth—pig bile in the form of tabloids prepared by Messrs. Burroughs, Wellcome, & Co.—in amounts carried from 1,500 up to 2,350 grains daily, and subcutaneously for a time in doses of the equivalent of from 120 to 360 grains twice a day. The effect was decidedly favorable, and great improvement in the patient's general health followed the further administration of smaller doses for a time twice a week.

In the course of five weeks 48,000 grains of bile were administered, inclusive of 3,610 grains given subcutaneously and more than 1,000 grains injected into the substance of the thyreoid gland itself. Yet there were no symptoms of cholemaemia; on the contrary, the feeling of general well-being was distinctly promoted by the use of the remedy. What became of all this bile the author does not profess to explain; it did the work expected of it, and it did no harm. Evidently Dr. Allan's pioneer work in the direction indicated is worthy of being followed up.

HYSTERICAL SIMULATION OF APPENDICULAR DISEASE.

Of the mimicry of the symptoms of organic disease by hysteria there seems to be no end. H. Nolhagel (Wiener klinische Wochenschrift, 1889, No. 15; Deutsche Medizinal-Zeitung, August 17th) reports the case of a neuroasthenic young man who for two years had seemed to have appendicular inflammation. His abdomen was opened, but nothing abnormal was found, although at the outset a pathological resistance to palpation had been thought to exist. The pains continued to occur, without, however, any fever, any vomiting, or the slightest physical sign, but there was such exquisite cutaneous sensitiveness as is never a feature of genuine perityphlitis. The reflexes were exaggerated, and the visual field was restricted.

RASHES AFTER ENEMATA.

The fact that rashes are occasionally consequent on enemata is not altogether unknown, but it is probable that, owing to its want of mention in manuals of dermatology, it is not so widely known as it ought to be. Dr. T. K. Monro (Glasgow Medical Journal, September) therefore does good service by calling attention to the subject and recording six cases of his own. It is possible that rashes really due to the administration of an enema are occasionally classed among surgical or puerperal rashes, or drug eruptions, hence it is well that the practitioner should bear in mind the enema as a factor in rash production. Such rashes are divided into
three types—scarlatiform, mealy, and small-scaled urticaria—but more than one form may be present. They appear to be more common in women than in men and in adults than in children. They may or may not be associated with burning or itching. The distribution appears to be irregular, the buttocks and then the face being the more common seats, but all parts of the body being liable to invasion. Rise of temperature and acceleration of pulse are uncommon. The production of the rash is variously attributed to febrile absorption from the injected fluid softening the contents of the bowel, the absorbed material being excreted by the skin; or to the use of hard yellow soap, for such rashes have not been recorded as following enema of soft soap. The interval elapsing between the enema and the appearance of the rash is said to be commonly about twelve hours, but may vary between two and twenty-four hours.

**Surgical Instruments Not Dutiable.**

We are glad to learn, through the *Railway Surgeon* for August 22d, of a most important decision which was recently handed down by Judge Colt, of the United States circuit court, reversing the decision of the board of appraisers, which held that surgical instruments imported to this country were dutiable. The court holds that the instruments are not dutiable, being "scientific instruments" within the meaning of the law. The importance of this decision to the profession at large, no less than to the individual practitioner, can not be overestimated.

**The Mississippi Valley Medical Association.**

We look to see the meeting in Chicago next week well attended, and the programme adhered to closely. The profession of the entire country, not merely that of the valley of the Mississippi River, is deeply interested in the association's proceedings, and probably many physicians who are not members will be present at the meeting.

**Brain Trouble from Ligation of the Internal Jugular Vein.**

Ligation of the internal jugular vein of one side is for the most part not followed by serious consequences. Kummer, however (Revue de chirurgie, April; Centralblatt für Chirurgie, August 12th), relates a case in which death in coma took place in five hours after an operation in which such ligation was resorted to because the vessel was wounded. Venous engorgement was found in the pia and in the choroid plexus, there were two circumscribed foci of hyperemia in the frontal lobes, and there were extravasations of blood into the ventricles. He refers also to a case occurring in von Bruns's clinic, but in that instance there was hyperplasia of the opposite jugular and death was slower in occurring.

**Phimosis and Organic Stricture of the Urethra.**

Guyon's dictum that inflammatory strictures of the urethra are always of gonorrheal origin meets with an obvious exception in the case of traumatic strictures, but P. Comte, of Lyons (Archives provinciales de chirurgie, 1899, Nos. 3 and 4), takes the ground that this is not the only exception. He thinks it is not very

common for a deep organic stricture to form in consequence of the irritation of urine retained habitually between the prepuce and the glans or behind a stenotic meatus urinarius externus. P. Stolper, of Breslau, whose abstract of Comte's article appears in the Centralblatt für Chirurgie for August 26th, remarks that narrowing of the meatus is not rarely the result of a defective operation for phimosis. In cases of simple incision of the prepuce, he says, if it is not thoroughly separated from the glans, a perversion of the shape of the latter is apt to occur, with cicatricial stenosis of the urethra, from contraction of the incised prepuce.

**The Poisonous Dogwood of Victoria.**

Occasionally we hear of new plants that, like the various species of *rhus*, are capable of producing an irritating effect upon the skin. One of these, the Cassina (or Cassinia) aculeata, known in Victoria as dogwood, is reported by Noyes (Intercolonial Medical Journal, July 20th) as having caused dermatitis in a number of cases that he has observed. He gives brief notes of seven instances of its poisonous action.

**Christian Science from a Physician's Point of View.**

In the October number of Appletons' Popular Science Monthly is a remarkably clear and logical exposé of this gigantic imposture by Dr. John B. Huber. It is not only of argumentative value, but it is eminently readable. The author's closing sentences are well worth quoting with commendation: "The observer," he says, "will find in Christian Science much charlatanry (by which many honest fanatics are deceived), much to surprise reason and common sense, to offend good taste and the proprieties, to outrage justice and the law, and to mortify the pious. And in the last degree reprehensible will appear this cult's ghastly masquerade in the garb of Him that prayed in the Garden of Getsemane, 'the pale, staggering Jew, with the crown of thorns upon his bleeding head,' the tenderest, the divinest, the most mankind-loving personality the world has ever known."

**Items.**

An Honor to a New York Physician.—We learn that the King of Greece has conferred on Dr. Achilles Rose the silver cross of the Knights of the Royal Order of the Saviour.

Changes of Address.—Dr. Samuel M. Brickner, to No. 136 West Eighty-fifth Street, New York; Dr. Carl E. Elfstrom, to No. 437 Pacific Street, Brooklyn.

Marine-Hospital Service Health Reports.—The following cases of small-pox, yellow fever, cholera, and plague were reported to the surgeon-general during the week ending September 23, 1899:

### Items.

**GILL, Charles R.**, Acting Assistant Surgeon, United States Army, will proceed to Fort Hamilton, New York, for medical treatment at that place.

**GREENLEAF, Charles R.**, Colonel and Assistant Surgeon-General, United States Army, will proceed to Honolulu, Hawaiian Islands, for the purpose of inspecting the medical department and the sanitary condition of the post and camps in that vicinity.

**HALLWOOD, J. B.**, Acting Assistant Surgeon, United States Army, will proceed to Matanzas, Cuba, for duty with the depot battalion, Tenth Infantry, to accompany it to Fort Crook, Nebraska.

**KELLOGG, P. S.**, Acting Assistant Surgeon, United States Army, is assigned to duty on the transport Centennial during the voyage of that vessel to Manila.

**KIEFFER, Charles F.**, Captain and Assistant Surgeon, United States Army. The leave of absence granted him is extended twenty-three days.

**KIRKPATRICK, T. J.**, First Lieutenant and Assistant Surgeon, is granted sick leave for one month, with permission to apply for an extension of two months.

**PORTER, Elias H.**, Acting Assistant Surgeon, United States Army, will proceed to Fort Hancock, New Jersey, to relieve GLEMAN, Louis L., Acting Assistant Surgeon, United States Army, who will proceed to New York for duty.

**ROSS, John**, Surgeon, United States Navy, retired, is assigned to duty in connection with municipal hospitals and charities as an assistant to the chief surgeon, and will be prepared to relieve Dr. C. L. Furbush.

**SIMMONTON, A. H.**, Acting Assistant Surgeon, United States Army, will proceed to Cienfuegos Barracks, Cuba, for duty with the depot battalion, Second Infantry, to accompany it to Fort Thomas, Kentucky.

**STUART, S. MacCandless**, Acting Assistant Surgeon, is assigned to duty attending all enlisted sick men in quarters in Manila, whose organizations are in the field, relieving LOWELL, CHARLES H., Acting Assistant Surgeon, United States Army.

**TAYLOR, Hugh L.**, Acting Assistant Surgeon, United States Army, will proceed to Vancouver Barracks, Washington, for duty with the battalion of the Thirty-ninth Infantry.

**WARE, ISAAC P.**, Captain and Assistant Surgeon, United States Army, will proceed to Benicia Barracks, California, for station at that post, awaiting result of retiring board.

**WHITE, George Reeves**, Acting Assistant Surgeon, United States Army, will report for temporary duty at the United States General Hospital, the Presidio, California, awaiting transportation to the Philippine Islands.

**WILSON, James S.**, First Lieutenant and Assistant Surgeon, will, upon his arrival at Manila, report to HALL, WILLIAM R., Major and Surgeon, United States Army, for examination as to his fitness for promotion.

**WILSON, William H.**, Captain and Assistant Surgeon, United States Army, will proceed to Angel Island, California.

**ZAUNER, Robert H.**, Acting Assistant Surgeon, is assigned to the Twentieth United States Infantry, Fort Santiago, Manila.
Naval Intelligence.—Official List of Changes in the Medical Corps of the United States Navy for the Two Weeks ending September 23, 1899:

BALDWIN, L. B., Surgeon. Placed on the retired list.
BARBER, GEORGE H., Passed Assistant Surgeon. Detached from the Monongahela and ordered to duty at the Naval Academy.
BLAKEMAN, R. S., Assistant Surgeon. Ordered to the Naval Hospital, Newport, Rhode Island, on completion of preliminary examination for promotion.
LOVERING, P. A., Surgeon. Detached from the recruiting rendezvous, Buffalo, and ordered to proceed home.
LUMSDEN, G. P., Surgeon. Detached from the Richmond and ordered to the recruiting rendezvous, Buffalo.
MARSTELLER, E. H., Surgeon. Detached from the recruiting rendezvous, Buffalo, and ordered to the Richmond.
ROTHGAGER, GEORGE, Passed Assistant Surgeon. Ordered to duty at the United States Naval Hospital, New York.
SNYDER, J. J., Assistant Surgeon. Detached from the Naval Hospital, Newport, Rhode Island, and ordered home to await further orders.
STONE, M. V., Assistant Surgeon. Detached from the Brooklyn and ordered to the Asiatic Station.

Marine-Hospital Service.—Official List of Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the United States Marine-Hospital Service for the Seven Days ending September 21, 1899:

BANKS, C. E., Surgeon. Granted leave of absence for one day.
Pleckham, C. T., Surgeon. To proceed to Eagle Pass and Laredo, Texas, as inspector.
McINTOSH, W. P., Surgeon. To proceed immediately to Meridian, Mississippi, and report by wire to Surgeon H. R. Carter at New Orleans for special temporary duty.
WENNEBARGER, C. P., Passed Assistant Surgeon. Leave of absence extended sixteen days on account of sickness.

FRICKS, L. D., Assistant Surgeon. Directed to assume temporary charge of the service at Key West, Florida, relieving Assistant Surgeon McDAM.
McADAM, W. K., Assistant Surgeon. Relieved temporarily from the hospital at Key West and detailed for special duty in connection with the yellow-fever epidemic at Key West.
Hallett, E. B., Acting Assistant Surgeon. Granted leave of absence for one day.
DavIs, H. E., Hospital Steward. Upon the arrival of Steward WarHANIc, to rejoin station at Boston.
WarHANIC, C. T., Hospital Steward. Relieved from duty at Chicago and directed to proceed immediately to Baltimore for temporary duty and assignment to quarters.

Appointment.

W. J. W. Woolgar, of Ohio, to be acting assistant surgeon for duty at Cleveland.

Society Meetings for the Coming Week:

MONDAY, October 2d: New York Academy of Sciences (Section in Biology); German Medical Society of the City of New York; Morrisania Medical Society, New York (private); Brooklyn Anatomical and Surgical Society (private); Corning, New York, Academy of Medicine; Utica, New York, Medical Library Association; Boston Society for Medical Observation; St. Albans, Vermont, Medical Association; Providence, Rhode Island, Medical Association; Hartford, Connecticut, Medical Society; Monmouth, New Jersey, County Medical Society (Freehold); South Pittsburgh, Pennsylvania, Medical Society; Chicago Medical Society.

TUESDAY, October 3d: Mississippi Valley Medical Association (first day—Chicago); New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Elmira, New York, Academy of Medicine; Ogdenburg, New York, Medical Association; Syracuse, New York, Academy of Medicine; Medical Societies of the Counties of Broome (annual), Columbia (semiannual—Chatham), Orange (semiannual—Goshen), and Washington (semiannual), New York; Hudson (Jersey City) and Union (quarterly), New Jersey, County Medical Societies; Androscoggin, Maine, County Medical Association (Lewiston); Chittenango, Vermont, County Medical Society; Baltimore Academy of Medicine; Medical Society of the University of Maryland (Baltimore).

WEDNESDAY, October 4th: Mississippi Valley Medical Association (second day); New York Academy of Medicine (Section in Public Health); Society of Alumni of Bellevue Hospital; Medical Microsociological Society of Brooklyn; Medical Society of the County of Richmond, New York (New Brighton); Penobscot, Maine, County Medical Society (Bangor); Bridgeport, Connecticut, Medical Association.

THURSDAY, October 5th: Mississippi Valley Medical Association (third day); New York Academy of Medicine; Brooklyn Surgical Society; Society of Physicians of the Village of Canandaigua, New York; Washington, Vermont, County Medical Society; Boston Medical-psychological Association; Obstetrical Society of Philadelphia; United States Naval Medical Society (Washington); Medical Society of City Hospital Alumni, of St. Louis; Atlantic Society of Medicine.

FRIDAY, October 6th: Mississippi Valley Medical Association (fourth day); Practitioners' Society of New York (private); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society.

SATURDAY, October 7th: Manhattan Medical and Surgical Society, New York (private); Miller's River, Massachusetts, Medical Society.

Births, Marriages, and Deaths.

Married.

DANIELS—CUSHMAN.—In Pensacola, Florida, on Tuesday, September 19th, Mr. Henry S. Daniels and Miss Kate Gordon Cushman, daughter of Dr. H. C. Cushman.

WHITE—CLAPP.—In Wellesley Hills, Massachusetts, Dr. George Rantoul White and Miss Irma May Clapp.

Died.

CUSACK.—In Orange, New Jersey, on Wednesday, September 29th, Dr. T. George Cusack.
Zimmer.—In Rochester, New York, on Monday, September 18th, Minnie Wolff Zimmer, wife of Dr. John Zimmer.

Special Articles.

THE LAW IN ITS RELATIONS TO PHYSICIANS.
By ARTHUR N. TAYLOR, LL.B.

(Continued from page 404.)

XXXVIII.

CRIMINAL LIABILITY.

Criminal Liability arises when Conduct becomes a Public Menace.—The liability of the physician resulting from the improper or wrongful exercise of the functions of his profession which has heretofore been the subject of examination is that of a civil nature, which was satisfied with a payment of an adequate compensation to the particular patient who was thereby injured. Usually in such cases of nonfeasance or malfeasance, the injury produced and the resulting right of prosecution is a matter affecting only the immediate parties to the transaction—viz., the physician and the patient—and is one in which third parties generally, or, in other words, the public or State, have no concern whatever. It is evident, however, that there may be cases in which the act complained of is so grossly unprofessional as not only to cause an injury to the patient for which he is entitled to compensatory damages but to amount as well to a serious menace to the peace and safety of the public. Such an act will, in addition to the civil liability heretofore considered, give rise to another and more important liability in favor of the public or the State, known as a criminal liability.

Common Law and Statutes Regulate the Subject.—Our criminal law, like our law relative to civil matters, came from England as a part of the common law. To this many alterations and additions have been made in the several States by statutes, and in some few jurisdictions the common law relative to criminal matters is so abrogated by statutes that only those acts are considered as criminal which their legislatures have expressly declared so to be.*

The criminal law in its relation to the practice of medicine is in its nature very largely statutory, and differs in detail in the several jurisdictions; yet as a whole it is sufficiently uniform to render practicable a general treatment of the subject applicable to the several States.

Criminal Intent Presumed.—The civil liability of the physician, it has been observed, is based upon his failure to possess ordinary knowledge, or to exercise the usual or proper degree of care and diligence in applying the same. Such an act ordinarily lacks the essential element of a crime—viz., malice or a criminal intent—and can, therefore, be considered only in the light of a civil injury affecting the individual patient. That malice or criminal intent need not always be shown to exist, but may be implied from the character of the acts complained of, is, however, a well-recognized principle of the law, it being held that one is presumed to contemplate the natural consequences of his acts, and, if these consequences are so disastrous or so fatal as to justify a presumption of malicious intent, the act will be deemed criminal even though it is in fact the result only of negligent or reckless conduct.

Gross Ignorance and Reckless Negligence; English Doctrine.—Whether or not the ignorance of a physician may be so gross, or his conduct so grossly and recklessly negligent, as to render him guilty of homicide where the patient dies from his maltreatment is a question that has been several times before the English and American courts. The doctrine established by the English courts seems to be that if the ignorance or the neglect is gross, then the criminal intent will be implied. Chief-Justice Parker says: "I call it acting wickedly when a man is grossly ignorant, and yet affects to cure people, or when he is grossly inattentive to their safety." Some light is thrown upon the question of what degree of ignorance or what amount of negligence an English court considers gross by the words of Justice Miller, who says: "If a man knew that he was using medicine beyond his knowledge, and was meddling with things above his reach, that was culpable madness. Negligence might consist in using medicine in the use of which care was required, and of the properties of which the person using them was ignorant. A person who so took a leap in the dark in the administration of medicine was guilty of gross negligence."†

Early American Policy.—The policy of the American courts, as manifested in the earlier cases, was that of much greater leniency, their policy being to hold the defendant guilty only when an evil or mischievous intent could be shown. In more recent cases, however, our courts have followed the English precedents, and it is thought probable, will continue to do so, this doctrine being more in accord with the ever advancing spirit of medical and surgical science and better calculated to relieve the medical fraternity of those quacks and charlatans whose presence is a reproach upon the profession.

The earliest American case of any importance, and one which is doubly interesting because it not only illustrates the policy applied by our courts for over half a century, but also throws light upon the source of a system or school of medicine which enjoyed more or less patronage in this country for a number of years, is that of Commonwealth vs. Thompson. In this case, which was tried in 1809, Dr. Samuel Thompson, founder of the Thompsonian system of medicine, sometimes referred to as the botanical system or steam system, was tried for murder. The report of the case, it is thought, presents matter of sufficient interest to the medical profession to justify a liberal extract therefrom.

"On the trial it appeared in evidence that the prisoner, some time in the preceding December, came into Beverly, where the deceased then lived, announced himself as a physician, and professed ability to cure all fevers, whether black, gray, green, or yellow; declaring that the country was much impressed upon by physicians, who were all wrong, if he was right. He possessed several drugs, which he used as medicines, and to which he gave singular names. One he called coffee; another, well my-aris-tile; and a third, ramrods. He had several patients in Beverly and in Salem previous to Monday, the 2d of January, when the deceased, having been for

† Reg. vs. Markus, 4 F. and F., 356.
‡ Commonwealth vs. Thompson, 6 Mass., 184.
The evidence showed that the "coffee" was a decoction of marsh rosemary mixed with the bark of the bayberry bush, which was not supposed to have injured deceased. The emetic powder, upon which the prisoner said he chiefly relied in his practice, and which was so frequently administered to deceased, was the pulverized plant commonly known as Indian tobacco, or the Lo bella inflata of Linnaeus.

The prisoner in this case had been indicted for murder, but under the practice the jury could have found him guilty of manslaughter had they determined that the offense amounted to that crime only.

The court instructed the jury that to constitute the crime of murder the killing must have been with malice, either express or implied; that there was no express malice, and that they could not infer malice without being satisfied that the prisoner was willfully regardless of his duty and determined upon mischief.

Upon the question of the prisoner's guilt of the crime of manslaughter the court laid down the doctrine that the killing must have been a consequence of some unlawful act to constitute such a crime. This doctrine, it will be hereafter seen, has been distinctly repudiated by the supreme court of the same State in a recent decision. The court in this case continued: "Now, there is no law which prohibits any man from prescribing for a sick person with his consent, if he honestly intends to cure him by his prescription. And it is not felony if, through his ignorance of the quality of the medicine prescribed, or of the nature of the disease, or of both, the patient, contrary to his expectation, should die. The death of a man killed by voluntarily following a medical prescription can not be adjudged felony in the party prescribing, unless he, however ignorant of medical science in general, had so much knowledge or probable information of the fatal tendency of the prescription that it may be reasonably presumed by the jury to be the effect of obstinate, willful rashness, at the least, and not of an honest intention and expectation to cure." The court, after observing that if the evidence showed the administration of like remedies to have previously caused similar injurious or fatal effects, then the jury might have found the prisoner guilty of manslaughter, concluded its opinion as follows: "It is to be exceedingly lamented that the people are so easily persuaded to put confidence in these itinerant quacks, and to trust their lives to strangers without knowledge or experience. If this astonishing infatuation should continue, and men are found to yield to the impudent pretensions of ignorant empiricism, there seems to be no adequate remedy by a criminal prosecution, without the interference of the legislature, if the quack, however weak and presumptuous, should prescribe with honest intentions and expectations of relieving his patient."

Following this decision is one from the supreme court of Missouri, decided in 1844.* Here the prisoner was also a botanic physician. The patient, who was to be treated for "sciatica," was in the family way and lacked about six weeks of having completed the period of gestation. The patient's husband informed the accused of the patient's condition and told him that he had been cautioned against giving her vapor baths and emetics while in that condition. The accused declared his ability to treat the patient with perfect safety, and promptly began steaming and giving her lobelia. A few repeti-

* Rice vs. State, 8 Mo. 561.
tions of this treatment brought on a miscarriage, from the effects of which the patient died.

The court applied the doctrine enunciated in the case of Commonwealth vs. Thompson, and said that as no improper motive or knowledge of the fatal tendency of the treatment applied was shown the accused could not be held guilty.

The case of Hounard vs. People presents a question rather of fact than of law. The patient, who was five months advanced in pregnancy, was suffering from bilious fever; the accused was attending her and, as the evidence shows, was extremely careful about giving her strong medicine, and was in no way responsible for her miscarriage. After the labor pains commenced the accused was sent for. The patient's labor being ineffectual, the doctor undertook to remove the fetus by force. Of the first and, apparently, only presentation he succeeded in bringing away all but the head. Having no forceps, he undertook to improvise a substitute by the use of two spoons, but whether he used them to any extent is doubtful. Being himself ill, he gave up his endeavors to bring away the head and, going away, sent another doctor. The patient was then given ergot and, after a little time, the head and another fetus besides came away. The patient from that time had no physician for about a week—why, the evidence does not show—when puerperal fever set in, from which she died in about two days. The court, in considering the criminal liability of the accused, said: "He may not have acted with either the best judgment or even ordinary skill. But no unprejudiced person can read the evidence without being convinced that he acted with good motives, and the evidence wholly fails to show that the puerperal fever, of which the patient died, was caused by anything done or omitted to be done by the accused.

If physicians and surgeons can be convicted of manslaughter, and sent to the penitentiary, upon such evidence as this record contains, there would be witnessed a frightful devastation of their ranks. . . . There is wanting in this case every element of the crime of manslaughter, but that of the mere death of a human being."

In the case of State vs. Schultz, in which the accused professed to be a Baunscheidtist, the evidence showed that the accused treated the deceased by using an instrument consisting of fine teeth or needles all over her body and applying oil; he also gave eight drops of the oil internally as a cathartic. In regard to the oil, the accused testified: "Do not know what the oelum Baunscheidtii is made of; it is a secret of the inventor."

Upon the trial the court instructed the jury that "a party, whether he be a physician or specialist, has no right to hold himself out to the public as competent to treat diseases, and induce the public to employ him, unless he knows what the medicine is he uses, and its reasonable effect upon the human system; and to do so, and administer internally poisonous medicines in sufficient quantities to ordinarily produce death, and death is produced thereby, he would be guilty of murder. And if the defendant in this case, through gross ignorance of the medicine used, or its reasonable effect upon the deceased as she was at the time, caused her death by an overdose of poisonous medicine, he would be guilty as charged."

The supreme court, in reviewing the case, held that this instruction was not the law, and that the physician could not be held guilty unless in prescribing and treating the patient he had so much knowledge of the fatal tendency of the prescription that it might be reasonably presumed that he administered the medicine from an obstinate, willful rashness, and not with an honest intention and expectation of effecting a cure. Thus following, it will be observed, the cases of Commonwealth vs. Thompson and Rice vs. State.

Present American Policy.—Upon the other hand, a disposition to follow the English doctrine and hold the profession to a more strict criminal accountability was first manifested by the supreme court of Arkansas in 1889.*

Here the question arose upon a point of law as to the sufficiency of the facts alleged in the indictment. These facts alleged in brief were that the accused unnecessarily administered to the patient, who was undergoing pains of childbirth, a large quantity of morphee, by reason of which the labor pains were retarded; that he then administered to her large and excessive quantities of fluid extract of ergot, by reason of which she had convulsions, and that he then bled the patient in the arm. That he then improperly and carelessly attempted to deliver the child with forceps. That he then improperly and carelessly administered excessive quantities of chloroform, and then, improperly, etc., punctured the head of the child with a pocket knife, unnecessarily killing it; that he inserted his finger in the mouth of the child and forced its head out of the mouth of the vagina, then tied a rope around its neck, and with force and violence, and without due caution, delivered the child; and that without delivering the afterbirth he abandoned the patient, from the effects of which she died in about six days.

The court, after reviewing all the principal authorities, English and American, said: "The court is of the opinion that the indictment in this case is sufficient. Whether the appellees are criminally responsible for the death of Mrs. S—must depend upon the evidence. A felonious want of due care and circumspection in her treatment must be proved as alleged. For a mere mistake of judgment in the selection and application of the remedies and appliances named in the indictment, they would not be criminally liable. Were they grossly ignorant of the art which they assumed to practise? Did they manifest gross ignorance in the selection or application of the remedies? Were the remedies unusual, inapplicable, or rashly applied? Were appellees grossly negligent or inattentive? These are all questions of evidence."

The next case in point of time seems to be that of Commonwealth vs. Pierce,† passed upon by the same court that decided the case of Commonwealth vs. Thompson, but with quite a different result. Here the physician caused the patient to be wrapped in flannels saturated with kerosene for three days, from which her flesh became so burned and blistered that she died.

The counsel for the accused urged that if he made the prescription with an honest purpose and intent to cure the deceased, he was not guilty of the offense charged, however gross his ignorance of the quality and tendency of the remedy prescribed, or of the nature of the disease, and that to prove his guilt it must be shown that he had so much knowledge or probable

information of the fatal tendency of the prescription that the death may be reasonably presumed to be the effect of obstinate, willful rashness, and not of an honest intent and expectation to cure. This, it will be remembered, is the doctrine enunciated by the supreme courts of Massachusetts and Missouri in the cases of Commonwealth vs. Thompson and Rice vs. State. The supreme court of Massachusetts, however, in the present case, denied the correctness of this doctrine and declared that recklessness, in the moral sense of indifference as to the result of one's actions, could not be applied as a test of criminal responsibility. That in criminal matters, as in civil, there must be an external standard of what would amount to moral recklessness in a man of reasonable prudence. That if the prescriptions used were dangerous, according to common experience, one who made use of them could not escape responsibility upon the ground that he had less than the common experience. The court said: “Common experience is necessary to the man of ordinary prudence, and a man who assumes to act as the defendant did must have it at his peril. When the jury are asked whether a stick of a certain size is a deadly weapon, they are not asked further whether the defendant knew it was so. It is enough that he used and saw it such as it was.”

The principles laid down in this case have been followed in the late case of State vs. Gill,* and it is believed will be recognized by other courts as the correct law.

*(To be continued.)*

**Pith of Current Literature.**

**Iodide of Potassium as a Diagnostic Agent in Pulmonary Tuberculosis.**—Dr. Edward F. Wells (Journal of the American Medical Association, February 4th) says that when iodide of potassium is administered it is eliminated, in part, by the bronchial mucous membrane, and it has long been known that, as the result of such elimination, the bronchial mucus is increased, mainly by the addition of water; cough may occur or be increased, and rales may develop or be accentuated. These effects are especially prone to occur when the doses of the iodide given are small or moderate. Stricker suggested that the drug might be useful for diagnostic purposes in pulmonary tuberculosis, and Vetlesen put the suggestion to a practical test. He used the iodide in three-grain-and-a-half doses three times a day for two or three days in twenty-seven cases, obtaining a positive reaction in eight, and negative results in nineteen cases. In the cases in which the reaction was positive, expectoration and rales were increased, the tubercular foci being readily located by the exaggerated rales heard in the vicinity.

As soon as the author's attention was called to Vetlesen's paper he began a series of observations for the purpose of determining, if possible, whether we had in the iodide of potassium an agent of diagnostic value in pulmonary tuberculosis, and, if so, defining so far as practicable its limits of clinical usefulness.

As a result of a large number of investigations, he found that, generally speaking, it might be affirmed that in cases in which tuberculosis was proved to exist, but with inability to locate the lesion, the locality and extent of the affected area might be made evident by the development of rales; that in cases with rales and an apparent ability to demonstrate the extent of local involvement, the observer would be gratified with the clearness of the auscultatory evidence, and astounded at the revealed extent and distribution of the deposit, and that in suspected tuberculosis rales and bacillary expectoration might be obtained earlier than was possible by any other means. The rales were induced or intensified in the consolidated area because the fluid in the bronchi accumulated there, and, with coughing or deep breathing bubbling was produced. In the author's experience a reaction had been obtained in about two thirds of the cases in this class. The reaction varied with the individual; in some cases the rales present were simply intensified; in others distinctive rales were developed in localities where they were before absent; in some of these, and in others, fine bubbling sounds were diffused all over the chest, but with a distinct accentuation and definiteness of the rales in the consolidated areas; in yet others no changes were produced.

After reporting five illustrative cases the author concluded as follows: “I believe the iodide-of-potassium test, as described, to be free from danger and serious objections; that it lends itself readily to the exigencies of routine practice; and that in the early diagnosis of pulmonary tuberculosis and in defining the location and extent of the lesion, it is a useful addition to our diagnostic resources.”

Several speakers, commenting on the paper, suggested that, owing to the fact of the iodide admittedly inducing an increase in the catarrhal condition, its use at least demanded the greatest caution.

**An Early Symptom of Actinomycosis.**—Besnier (Lyonn médical; Revue médicale, August 30th) reminded the Society of Dermatology of the aphorism of Poncet: Every patient who without any ascertainable reason is unable to open the mouth is attacked by actinomycosis. The remark had reference to a patient who had great difficulty in opening the mouth, yet in whom the most minute examination revealed no cause. Five or six months later an abscess formed; pus containing the characteristic yellow grains appeared.

**Loss of Memory in Alcoholic Insanity.**—Dr. Savage (Clinical Journal, August 30th), in a clinical lecture on Alcoholic Insanity delivered at Bethlem Royal Asylum, London, said that with the loss of memory, which is not uncommon in alcoholic paranoias, there is loss of desire for alcohol in nearly every case. Regarding the patient in the North, to whom he had already referred, when Dr. Savage visited him he went after dinner into the billiard room and played billiards. Whisky and brandy and soda water were on a side table. The patient would go up and take a bottle of soda water, and would not touch the stronger drink; he had no desire for it. If he had begun to recover his memory, however, he would have begun to regain his desire for drink. Dr. Savage was asked some time ago to see a lady, the wife of a leading solicitor, who had drunk herself into temporary weakness and complete loss of recent memory. The husband said to him, “Do you think my wife will ever recover?” He replied, “She will probably recover her memory, but I advise you not to pray...”

---

PROCEEDINGS OF SOCIETIES.

for it, because if she gets back her memory she will also get back her desire to drink.” The husband said, “Oh, no; when she was comparatively well I dared leave a decanter of spirits about and she would never touch it.” Dr. Savage replied: “If she gets well she will take to drink again.” The next he heard of the case was that the lady had recovered her memory and also her desire to drink. So loss of memory in alcoholic cases may be a blessing in disguise.

**An Undescribed Pupil Phenomenon.**—A. Westphal (Neurologisches Centralblatt, February 15th; British Medical Journal, September 9th) refers to the contraction of the pupil when the orbicularis palpebrarum muscle is energetically contracted. It is necessary to ascertain beforehand that the pupil is not in a contracted state (necrosis) before testing. On asking the patient to close the eyelids firmly, and at the same time forcibly keeping the eyelids from closing, the pupil is seen to contract in the normal eye. In the case of eyes, however, whose reaction to light is feeble or absent (as in the case of Argyll Robertson pupil), the contraction of the pupil referred to as associated with the energetic contraction of the eyelids is in abeyance. This phenomenon—namely, the failure of contraction in association with that of the orbicularis—is the new phenomenon of Westphal. It has been found by him in tabes, in cerebral syphilis, and in paralyses, but could not be obtained in healthy subjects.

**Operative Measures for Gallstones.**—Dr. Ranrohff (Journal of the American Medical Association, September 16th), in a paper on Gallstones, says that while his experience in the surgery of the biliary ways is far from large, he feels warranted in submitting the following propositions for consideration: 1. The gallstones found in a gall bladder are generally formed together—that is, about the same time. Their removal will not be followed by recurrence unless a refection of the biliary ways occurs. 2. Cholecystotomy with drainage should be regarded as the normal operation. 3. Save in exceptional cases, the operation should be done at one time. 4. Ideal cholecystotomy or cholecystolysis is not to be recommended. 5. Cholecystectomy is rarely indicated in acute processes. It is more dangerous than cholecystotomy. Since most stones are formed in the gall bladder, cholecystectomy is the more radical operation. It should be reserved for chronic cases in which a restitution of the gall bladder to the normal can not be expected. 6. Cystostomy is a safe supplement to incision of the gall bladder for stones of the cystic duct. 7. Cholecystostomy with suture and drainage should be considered the routine procedure in common-duct stones. Incision of the duct through the duodenum or from an incision in the loin (Tuffier) will rarely be needed. 8. Cholecystenterostomy has a limited but distinct field of application—i.e., obstruction jaundice from malignant disease or impermeable cicatrical common-duct stenosis.

**Etiology of Night Terrors.**—Rey (Archiv für Kinderheilkunde, Bd. xxv, Heft 3 u. iv; American Journal of the Medical Sciences, September) has found in all of thirty-two cases of night terrors that adenoid vegetables were present. After removal the terrors subsided. He therefore believes that adenoids are the most frequent cause of this disturbance, acting by the production of a carbonic-acid poisoning produced by interference with respiration.

**Removal of a Foreign Body from the Bronchial Tube through the Tracheal Opening, with a Report of a Case.**

—Dr. A. Coolidge, Jr., presented a paper on this subject. (See page 475.)

Dr. T. A. de Blois, of Boston: I was very much interested in Dr. Coolidge’s paper, in which he intimated that this first operation for the removal of a foreign body in the trachea was successful. I desire to relate an accident which occurred a good many years ago at the City Hospital in Boston in which the foreign body was not removed. It was a case of a child in whom the tracheotomy tube was retained. It seemed as if the vocal cords had become very flabby, and whenever the tracheal tube was removed the dyspnœa would increase. It was therefore suggested that an O’Dwyer tube be placed in the larynx. This was done, and the child got on very well, but the tracheal wound was still kept open. It seemed as if the O’Dwyer tube was rather small, for the reason that it did not stay in place well, and the next larger size O’Dwyer tube was inserted in its place. The nurse had left the room, when the child appeared to be easy, but had not been gone three minutes after the second O’Dwyer tube was put in before they were alarmed by the coughing of the child, and on examination the tube had disappeared. I made an examination, first with a probe, the child being only half etherized and tossing about a good deal, so that it was impossible to differentiate the sensation of the probe’s touching the tracheotomy tube, or whether it touched the O’Dwyer tube in the trachea, because on percussion dullness was elicited about the bifurcation. An eosophageal forceps was introduced, but it was impossible to bend it at a sufficiently acute angle to go through the tracheotomy tube and to get down to where the object was supposed to have lodged; and we were not at all sure that the O’Dwyer tube was in the trachea. The child grew weaker and weaker until efforts at removal were abandoned. The child was about two years old. It rallied a little; pneumonia came on, and death followed at the end of twenty-four hours. It was a very distressing case to me. I believe if the proper instruments had been obtainable and a careful search had been made for the foreign body in the trachea the life of the child might have been saved. I am very glad indeed to hear of the successful removal of a foreign body through the tracheal opening, as in this case of Dr. Coolidge’s.

Dr. Henry L. Swain, of New Haven: I am personally very much obliged to Dr. Coolidge for enlightening me on a matter so important to us, and especially to the individuals who are brought to us for our opinion in this line of accidents. We are called upon to
Upon the Day of Dr. Coolidge

Dr. C. E. Bean, of St. Paul: Upon hearing the case cited by Dr. Coolidge, I am reminded of the case of a child, three years of age, that I saw two years ago, who had inhaled half of a peanut. I was called in consultation forty-eight hours after the accident and found pneumonia had already developed. The peanut had evidently lodged in the second division of the right bronchus. I performed a tracheotomy, searched for it to the best of my ability, and was unable to find it. I left the tracheal wound open, and treated the resultant pneumonia in the ordinary way. The child had quite a severe attack of pneumonia, which lasted for two weeks, at the end of which time expectoration began rather freely, and one day the piece of peanut suddenly came out. The child made a good recovery. From my experience with two similar cases just before this I had given an unfavorable prognosis to the parents, stating the child would die in probably twenty-four hours after the operation. There has been no recurrence of the pneumonia, and no appearance of any foreign body.

Dr. F. E. Hopkins, of Springfield: If it is in order to report cases in which no operation was done, I will mention that of a child, three years of age, who came under my observation three months after the supposed inhalation of a foreign body, a fragment of a chestnut shell. No one had observed the accident, and the presence of a foreign body was doubted by the medical attendant. The history, however, pointed pretty clearly in this direction; and physical examination located the obstruction in the left bronchus. I advised tracheotomy, to which the parents would not consent, and nothing was done. Four months later—that is, seven months from the date of the accident—the fragment of shell was coughed out.

Dr. John O. Roe, of Rochester: On writing an elaborate article on foreign bodies in the air-passages a short time ago, I started out with the generally accepted belief that a foreign body in the trachea was a very serious thing. But after studying the results in a great many of such cases I came to the conclusion that a foreign body in the trachea was not such a very grave thing after all, and that when it was causing no active or alarming symptoms nor in danger of leading to serious conditions, the best results are generally obtained by letting the foreign body alone, allowing Nature to expel it. This rule holds good in those cases where a body is smooth and round and not of a corrosive nature, for in a short time the foreign body almost always becomes loosened and expelled during the act of coughing. The parts also frequently become very tolerant of such foreign bodies. I found records of cases where foreign bodies were lodged in a bronchus for twenty-five or thirty years, and expelled at the end of that time without any ill effects to the patient whatever.

I recall an interesting case that I saw some time ago, where a child had swallowed a PUNCH-and-JUDY whistle, which became impacted at the lower part of the trachea. It was not small enough to enter a bronchus, and every time the child breathed it blew the whistle. I performed tracheotomy, and with a long curved forceps fished out the whistle.

Dr. M. R. Ward, of Pittsburgh: I wish to emphasize the statement made by Dr. Roe, that the best results in these cases are often obtained by non-operative treatment. I recall a case in point that came under my observation at the Mercy Hospital, Pittsburgh, during the Christmas holidays, a year ago. A child, six years
of age, had placed in its mouth a small, hollow glass ornament, globular in shape, such as is commonly used in the decoration of the Christmas tree. By accident it was drawn into the trachea, and in spite of the most violent paroxysms of coughing it could not be dislodged. The foreign body could not be located either by laryngoscopic or physical examination. As there were no urgent indications for an operation, the patient was kept under close observation, when on the third day after admission, much to our surprise and delight, the foreign body was expelled in one of the paroxysms of coughing. I am sure we would have experienced great difficulty in extracting, by operative procedure, such a fragile body from the trachea or bronchi, even had we been able to locate it.

Dr. A. W. de Roaldes, of New Orleans: Dr. Ward has just made a remark that I cannot agree with—namely, in calling our attention to cases getting well generally without operative intervention for the removal of the foreign body. I do not think we should advocate this let-alone policy. I perfectly agree with him in the case of certain foreign bodies which may be so situated that we know a priori they will be difficult to remove; but in a number of cases opening the trachea immediately after the accident gives excellent results. I must confess that in an experience of eight cases I have never failed but once to remove the foreign body. This child had broncho-pneumonia, and the chances were the foreign body could not have been removed by surgical measures. The patient died. The seven other patients were operated upon immediately and made good recoveries. Sometimes it is astonishing how, in a sudden spell of coughing, objects will be thrown out through the tracheal wound by keeping the lips of the trachea opened with threads passed on each side maintaining it wide open. I do not think we ought to place ourselves on record as advocating non-intervention in these cases. I understand very well, and can agree with Dr. Roe and Dr. Ward, that statistics show that a great many patients left alone have recovered; at the same time, when we remember the anxiety of the family, the excitement all around, when a child is brought to us after having inhaled a foreign body, I think it is more prudent to make an effort to remove the foreign body by surgical measures, if necessary, even if the attempt is followed by failure. I really believe now that with the aid of such means of examination as Dr. Coolidge has presented, with which I am not very familiar, an attempt should be made to extract the foreign body, if possible.

Dr. E. Fletcher Ingals, of Chicago: I rise particularly to emphasize the statement made by Dr. de Roaldes, because it seems to me that it would be a great misfortune if this society should place itself on record as favoring the do-nothing policy in cases of a foreign body in the trachea. It seems to me that the laryngologist who does not attempt to remove the foreign body is not doing his duty by his patient, unless the body is very small and smooth. In the case of a small, smooth but ton, or something of the kind, there would be a good excuse for delay. But in the majority of cases I think that laryngologists should adopt the general surgeon's precepts and open the trachea as soon as possible.

Dr. John O. Roe, of Rochester: I do not wish to be misunderstood in reference to this matter. I do not believe in letting all foreign bodies in the trachea alone. I had reference in my previous remarks to small, smooth foreign bodies not irritating or corrosive and not producing active symptoms. Almost invariably such objects are sooner or later expelled, resulting in no harm to the patient. Of course, in a case like that which Dr. Coolidge has reported, the foreign body should be removed by surgical interference, and I desire to congratulate the doctor on his skill.

Dr. M. R. Ward, of Pittsburgh: Like Dr. Roe, I do not wish to be placed on record as being unqualifiedly opposed to surgical intervention in the removal of all foreign bodies within the trachea. The remarks of neither of us could be interpreted in that light. We simply have counseled conservatism, and I wish to reassert that meddlesome surgery is not unknown to this portion of the anatomy. My own case, and that reported by Dr. Swain, will bear me out in the statement that the best interests of the patient are often submerged by non-intervention. The idea of resecting two or three ribs, and wholesale mutilation of the lung, in the fruitless search of a foreign body that could not be located previous to operation, does not appeal to the judgment of a conservative and conscientious physician.

Dr. G. V. Woollen, of Indianapolis: Dr. Ingals brought out the essential idea in this discussion—namely, what are the indications for operation?—and this appertains to any department of our calling. I had a case just about this time last year of a child who swallowed a grain of corn, the foreign body being lodged in the right bronchus, and, excepting paroxysms of violent coughing with some dyspnoea, there was no disturbance. I was called by a competent surgeon who had all the arrangements made for performing tracheotomy and attempting the removal of the foreign body. I opposed operative intervention, founding my opposition upon three facts: First, there were no immediate symptoms; second, the foreign body would probably be expelled sooner or later; third, we could operate if indications developed demanding it. I therefore declined positively to operate. The child carried the grain of corn six weeks. One argument advanced in favor of operation was that the corn would germinate and swell from moisture and heat and would impact itself more strongly and set up septic trouble. I could not agree to that, although I do not know what the experience of the profession is as to sprouting corn in the larynx. At the end of six weeks the corn was expelled. The germinal portion of the corn had melted, otherwise the grain was as perfect as it ever was. An interesting feature of the case, predicted by me, was that the patient was threatened three times with broncho-pneumonia, but it was easily controlled. I do not believe, however, in the do-nothing policy in all these cases. This point was emphasized by Dr. Ingals. A substance such as Dr. Coolidge removed in his case could not, I think, be expelled by any coughing efforts.

Dr. G. A. Leland, of Boston: I should like to ask Dr. Coolidge if he could see beyond the bifurcation, so that if he had a small foreign body to deal with he could locate it by his instrument.

Dr. G. Hudson Makuen, of Philadelphia: I should also like to ask if the tracheotomy was a recent one, if there was hemorrhage connected with it, or whether he did it through the old tracheotomy wound.

Dr. John W. Farlow, of Boston: Perhaps I can answer the question of Dr. Leland, as I saw the patient before he came under the observation and care of Dr. Coolidge. I saw the larynx plainly, and with a small mirror could see through the tracheal wound. A tracheotomy had been done many years before, and through
the tracheal wound with a mirror I could see down into the left bronchus. Without a tracheal tube, such as Dr. Coolidge advocates, it is hardly possible to see beyond the bifurcation. The patient had no symptoms of a foreign body at the time I saw him.

Dr. Coolidge: In this case the tracheotomy was an old one, and for that reason it was perhaps easier to extract the foreign body through the wound; but I see no reason why a tracheotomy done just previously to the exploration should much increase the difficulty or danger. In most cases it could be done deliberately, the bleeding stopped, and everything done aseptically.

(To be continued.)

Book Notices.

This book is in some respects unique. Its author is the senior member of a great Chicago firm of instrument makers, but the work is by no means a catalogue of the firm's wares; indeed, it presents many illustrations and descriptions of appliances not produced by Messrs. Truax, Greene, & Co.

Mr. Truax gives accurate descriptions of individual instruments, but for the most part he restricts himself in this respect to those that are representative of some essential idea. More than that, he gives general descriptions—and most admirable ones they are—of classes of instruments, with excellent definitions of the names by which they are known. In many instances also he gives lists of the instruments and other appliances that may be required in the performance of particular operations, a most useful feature for the inexperienced practitioner. As he is very clear and careful in his language, his meaning is quite obvious, and this is a rare excellence in writings descriptive of mechanical contrivances.

The preparation of the book has evidently cost Mr. Truax a vast amount of time and labor, but we do not doubt that he will be rewarded by many an expression of appreciation by the medical profession. He has produced an attractive and valuable work.

A NEW ENCULATION FORCEPS.

By George F. Sucker, M. D., Toledo, Ohio.

The following figure is practically self-explanatory. However, a word or two concerning the advantages of the forceps may not be amiss.

Heretofore we have had no suitable enculation forceps for grasping the eyeball which was intended to be preserved intact for pathological examinations or sections. Then, too, we have had no forceps which would obviate the rupturing of the globe when that was imminent during an enculation; for the ordinary encula-

tion forceps only grasped the anterior section of the eye, and its teeth usually pierced the sclera, at the same time offering no uniform support, while this one offers just the reverse effects.

This forceps is based upon the principle of an obstetric forceps—i.e., one blade is inserted at a time and then the two are locked, as can be seen in the illustration.

After the eyeball has been freed, as is customary in an operation for enculation, one blade is introduced as far back as possible, then the other is likewise applied and both are locked. This being done, the eyeball is
lodged between the blades and the optic nerve extends
beyond the aperture as represented in the cut. The
scissors are now passed along the curve of the forceps,
and everything beyond its grasp is severed.
With this instrument one exerts uniform pressure
and can obtain considerable traction, thus enabling one
to sever the optic nerve well back and not close up to the
sclera, as is usual with the old enucleation forceps.
The inner surfaces of the blades are corrugated, thus
allowing the globe to remain firmly fixed.
The joint A is a set screw, thus allowing the blades
to be locked at any angle desired.
The points B are mouse-toothed, thus firmly fixing
the points when the forceps is locked at the handle.
The distance between the blades C is equal to the
greatest diameter of the eyeball. D is a catch on the
handle.
Various sized blades can be made for either very
large or small eyes. However, an average distance
of twenty-four millimetres is sufficient for all purposes.
The mechanism is very simple and permits the instru-
ment to be perfectly sterilized. The blades are very
thin, hence occupy very little space when inserted.

**Miscellany.**

The Mississippi Valley Medical Association.—The
twenty-fifth annual meeting will be held in Chicago, on
Tuesday, Wednesday, Thursday, and Friday, October
3d, 4th, 5th, and 6th, under the presidency of Dr. Dun-
can Eve, of Nashville. In addition to the president's
address, the programme includes, besides an address
in medicine, by Dr. J. A. Witherspoon, of Nashville,
and an address in surgery, by Dr. Lewis S. McMurtry,
of Louisville, the following titles: Enzymes and Immu-
nity, by Dr. Charles T. McClintock, of Detroit; Recent
Physio-chemical Researches as to the Physiological Ac-
ction of Lechithin and other Organic Phosphorus Com-
ounds, by Dr. L. H. Warner, of Brooklyn; Communal
Hygiene, by Dr. Ernest B. Sangree, of Nashville; Some
Phases of Malaria; Quinine in, by Dr. William Britt
Bruns, of Deckerville, Arkansas; The Treatment of
Cystitis, by Dr. M. F. Lee, of Columbus, Ohio; Diabetes
and its Constitutional Treatment, by Dr. Elmore S.
Pettyjohn, of Alma, Michigan; The Treatment of Pul-
monary Tuberculosis by Inhalation of Antiseptic Nebu-
las, by Dr. Homer M. Thomas, of Chicago; The Manage-
ment of Cases of Pulmonary Phthisis at Health Resorts,
by Dr. Charles F. McGahan, of Aiken, South Carolina;
The Treatment of Acute Lobar Pneumonia, by Dr.
Ramon F. Garcein, of Richmond, Virginia; The Art of
Diagnosis, by Dr. E. L. Larkins, of Terre Haute, Indi-
ana; The Successful Treatment of a Case of Graves's
Disease as an Auto-intoxication, by Dr. Charles L.
Minor, of Asheville, North Carolina; Do we Need to
Think? by Dr. William O'Neal Mendenhall, of Rich-
mond, Indiana; The Evils: their Causes, and the Rem-
edy that will Edify Medicine in the United States, by
Dr. A. M. Osness, of Dayton, Ohio; Two Cases of
Typhoid Fever with Unusual Complications in very
Young Children, by Dr. E. B. Montgomery, Quincy,
Illinois; Further Observations on the Treatment of the
Abdominal Viscera through the Colon, by Dr. Fenton
B. Turck, of Chicago; A Report of a Case of Complete
Hernia of the Pregnant Uterus, by Dr. W. V. Anderson,
of Toledo, Ohio; Leptomeningitis, by Dr. Frank Par-
sons Norbury, of Jacksonville, Illinois; The Pathogene-
sis of Functional Nerve Diseases and its Prophylactic
Indications, by Dr. John Punton, of Kansas City; The
Association of Hysteria with Organic Disease of the
Nervous System, by Dr. Philip Zeuner, of Cincinnati;
The Clinical Psychiatrist in General Practice, by Dr.
C. H. Hughes, of St. Louis; Temperament and its In-
fuence, by Dr. Albert E. Sterne, of Indianapolis; Ob-
struction and its Radical Treatment, by Dr. Thomas C.
Martin, of Cleveland; Intestinal Auto-intoxication; its
Prevention and Treatment, by Dr. William F. Barclay,
of Pittsburgh; Indigestion in Infants and Children,
by Dr. James H. Taylor, of Indianapolis; Lithiasis,
by Dr. Alexander Bate, of Louisville; Nephrolithiasis,
by Dr. A. H. Cordier, of Kansas City; The Therapeutics
of Infectious Conjunctivitis, by Dr. Dudley S. Rey-
nolds, of Louisville; Suprapenial Gland as a Therapeu-
tic Agent in Ophthalmology, Otology, and Rhinology,
by Dr. Flavel B. Tiffany, of Kansas City; Introversi-
on of the Iris, by Dr. L. W. Beardsley, of St. Louis; A
Contribution to the Study of Lung Reflexes, by Dr.
Marion K. Bowles, of Joliet, Illinois; The Treatment of
Dysentery, by Dr. J. W. Knowlton, of Paint Rock,
Alabama; Vesico-rectal Anastomosis, by Dr. J. Frank,
of Chicago; Intolerant Ulceration of the Rectum, with
a Report of Five Cases, by Dr. Sterling B. Taylor,
of Columbus, Ohio; The Modern Surgical Treatment of
Hæmorrhoids, by Dr. Gustavus M. Blech, of Chicago;
Haemorrhage from the Rectum and its Varied Impor-
tance as a Symptom, by Dr. Leon Straus, of St. Louis;
The Treatment of Certain Ocular Diseases by Excision
of the Cervical Sympathetic Ganglia, by Dr. James
Moores Ball, of St. Louis; Urethral Endoscopy, by Dr.
W. R. Blue, of Louisville; Inflammation of the Veru-
montanum, by Dr. J. Rilius Eastman, of Indianapolis;
The Techniques of Abdominal Incision, Peritoneal and
Extraperitoneal, by Dr. S. E. Milliken, of Dallas, Texas;
Mammoth Ovarian Cysts; Report of a Tumor weighing
Two Hundred and Forty-five Pounds, by Dr. James B.
Bullit, of Louisville; Some Causes of Death after Ab-
dominal Section, by Dr. Louis Frank, of Louisville; The
Value of Prostatic Examination, by Dr. J. Leland
Boogher, of St. Louis; Intestinal Obstruction from
Gallstones, by Dr. J. Wesley Bovée, of Washington;
Obstructive Growth of the Pylorus, with a Report of a
Successful Case of Pyleroectomy, by Dr. J. E. Allaben,
of Rockford, Illinois; What becomes of the medicinally
treated Cases of Appendicitis? by Dr. Louis Schoeller,
of Des Moines, Iowa; Appendicitis from a Medical
Standpoint, by Dr. I. N. Love, of St. Louis; A Plea for
Early Operation in Appendicitis, by Dr. A. M. Hayden,
of Evansville, Indiana; The Surgical Features of Appen-
dicitis, by Dr. Hal C. Wyman, of Detroit; A Study of
Twenty-seven Cases of Appendicitis, by Dr. Frank T.
Merriwether, of Asheville, North Carolina; Certain
Special Features in Hernia of the Female, by Dr. T. H.
Manley, of New York; The Surgery of the Turbinated
Bones, by Dr. J. A. Stucky, of Lexington, Kentucky;
Nasal Stenosis due to Defective Sæpta and its Treat-
ment, with or without Thickening of the Convex Side,
by Dr. John J. Kyle, of Indianapolis; Mastoid Opera-
tion, with a Report of Cases, by Dr. George F. Keiper,
of Lafayette, Indiana; Beta-eucaine as an Anesthetic
in Eye Surgery, by Dr. W. H. Poole, of Detroit; The
Surgical Treatment of Chronic Frontal Sinusitis, by
Dr. Richmond McKinney, of Memphis; Observations on
MISCELLANY.

The International Congress on Tuberculosis.—Science for September 15th states that the report of Sir Herbert Maxwell, M. P., F. R. S., and Dr. Pye-Smith, F. R. S., the delegates of the British government at the International Congress on Tuberculosis held at Berlin between May 24th and 27th last, has been issued as a parliamentary paper. The report states, as abstracted in the London Times, that the congress, which was opened by the Herzog von Ratibor, in the presence of the German Empress, consisted of a hundred and eighty delegates, appointed by and representing different states and universities and other public bodies. A number of papers were read, chiefly by German delegates, but nothing in the nature of a general discussion took place. The proceedings when printed will form a valuable corpus of scientific opinion on the subject.

Dr. Pye-Smith adds a memorandum on the medical aspect of the results of the congress. After giving in some detail the most important conclusions which were recognized—that consumption and other tuberculous diseases are caused by the presence and multiplication of the specific bacillus discovered by Professor Koch; that tuberculosis, as a condition directly transmitted by inheritance, is extremely rare; and that phthisis, or pulmonary tuberculosis, in particular, is not catching,—Dr. Pye-Smith goes on to describe the following practical points in the prevention of tuberculosis as a widespread and destructive disease which were inculcated by various speakers at the congress:

A. The primary importance of free ventilation and wholesome and abundant food. Improvement in the dwellings and the food of the poorer classes in this country and their increasing cleanliness and sobriety have not only diminished sickness generally, but have directly reduced the number of deaths from consumption until the mortality from this cause is less in London than in any other large city. (It is, however, important to notice that the death-rate of young children from disease of the bowels has little if at all diminished. See Sir Richard Thorne’s Harben Lectures.)

B. The prevention of infection of the lungs by the bacillus of tubercle depends chiefly on the rational treatment of the spuita of consumptive patients, or rather, for practical purposes, of the sputa of all those affected with cough and expectoration. The phlegm should never be deposited on the ground or on a handkerchief, where it can dry up; it should be kept moist until it can be destroyed by heat, and the vessel used to receive it should contain phenol or some other antiseptic solution.

C. The prevention of infection by tuberculous milk may be accomplished either by boiling all milk given as food to children or by inspection of dairies, so as to prevent tuberculous milk cows being used.

D. The prevention of infection by meat can be secured by careful and thorough inspection of carcasses, or by diagnostic testing of cattle with tuberculin. This, the only undoubtedly useful application of the so-called tuberculin, has the drawback that after the effect of the inoculation has passed off a tuberculous animal becomes immune to it for a time, and so may be passed as healthy. (It is said that cattle suspected of tubercle are thus rendered immune to the tuberculin test before being sent over the French frontier.)

Though the question of the treatment of phthisis was only a supplementary part of the work of the congress, Dr. Pye-Smith gives the following facts, which are, he says, “important for the people as well as their governors to be aware of”:

a. That tuberculous disease of the bones and joints, of the glands and skin and abdomen, though dangerous, is not incurable, and, by the modern methods of operative medicine, is in most cases successfully cured.

b. That tuberculosis of the lungs (phthisis, or consumption) is frequently cured, and probably more often now than formerly. (Cursehmann, of Leipsic, fourth day of congress.)

c. That there is no specific drug which has direct influence upon consumption, but that many, both old and new, have valuable effects upon its complications.

(On the Action of the New Tuberculin, see Briger’s paper, on the second day of congress, and Dr. C. T. Williams in the Royal Medical and Chirurgical Society’s Transactions for the present year.)

d. That abundant food, particularly of a fatty nature, and a life in the open air, are no less valuable in the treatment than in the prevention of phthisis, and that the hospitals and asylums for providing these essentials, which are now numerous in Germany, and far from rare in England, Austria and Hungary, France and the United States, are of essential value. That the “open-air treatment” has been long known and practised in the United Kingdom was handsomely acknowledged by Professor von Leyden, first day of congress. Compare papers by Kaurin (Norway), Westhoven (Ludwigshaven), J. B. Walters (London), Desider Kuthy (Budapest), Schmidt (Switzerland), Domene (Spain), fourth day.

e. That the influence of climate, altitude, temperature, and dryness of the air and soil, of traveling and of sea voyages has been very differently estimated at different periods, and that, while each is in various degrees important, popular opinion probably exaggerates their power. (Herman Weber, of London, fourth day of congress.)

f. That the prospect of improved success in the treatment of tuberculosis in general, and of pulmonary tuberculosis in particular, by the advance of pathology and the progress of surgery and medicine, is a hopeful one, almost as hopeful as that of limiting the spread of the disease by preventive measures.

Primitive Surgery of Dislocations.—According to an editorial in the Medical Age for August 25th, some of the nomadic tribes inhabiting the interior of Afghanistan, living as they do hard and isolated lives, entirely away from the scientific and medico-surgical progress of the world, maintain to this day some of the most primiti-
tive of practices for righting themselves whenever they suffer from accidents involving a dislocation of bones. The method commonly employed by them for the reduction of dislocations is certainly original, and naturally more successful than similar operations upon European or American subjects would be. For the dislocation of the thigh, the unfortunate patient is sweated and starved for three or more days in a dark room, the atmosphere of which is heated by fires kept burning night and day; and the effects of this high temperature are further increased by drenching with copious draughts of warm rice water or thin gruel. While this treatment is being enforced, a fat bullock or buffalo is tied up and fed ad libitum with chopped straw flavored with salt, but is rigidly denied a drop of water or other liquid. Usually on the third day the patient is made to ride the animal astride, a felt alone intervening between him and the hide, his feet being drawn down and fastened tightly under the animal’s belly by cords passing around the ankles. These preliminaries arranged, the animal is led out to water, where it is allowed to drink so greedily and inordinately that its belly swells to nearly double its former size. The stress produced by this upon the dislocated limb is sufficient to bring the wandering bone back to its socket, or else it produces more serious results, liable to render the sufferer a helpless cripple for life.

The method of reducing a dislocated shoulder is quite as curious and interesting. It is managed thus: The hand of the dislocated member is firmly fixed as closely to the opposite shoulder as it can well be, by cords tied around the wrist. Then between the bend of the elbow and the chest is placed an empty goatskin bag, in common use throughout Oriental countries as a means for carrying water, which is gradually filled. The slowly increasing weight suffices to overcome the resistance of the muscles before they have borne it very long, and, as in the previous instance quoted, either betterment or further injury soon results. These water bags, when full, weigh close upon a hundredweight, and occasionally more than that. For a reduction of dislocation of the ankle joint, the injured extremity is placed in a hole dug in the ground and covered over with soft earth, firmly pressed down. The limb is then pulled out by force, and with a fair chance of the joint returning to its former shape and position.

McGill University proposes, according to Science for September 1st, to erect at the cost of seventy thousand dollars a building for its departments of hygiene, pharmacology, and medical jurisprudence. In the medical department of this university Dr. T. J. W. Burgess has been appointed professor of mental diseases.

Experience, Judgment, and Luck.—Dr. Nelson W. Wilson (Buffalo Medical Journal, September) tells the following trenchant stories:

"When a new doctor begins practice he takes his first lesson in experience—judgment follows as a matter of course. If the Lord is with him, and his patient has fighting powers, his judgment is apt to be good. In other words he has luck. Three cases will illustrate the triple title of this article.

I. "In the days of the first flush of college weaning, when the faculty had signed themselves down on my diploma, and the great State of New York, through the regents, had officially certified to my ability to practise medicine and surgery, and given me a legal right to charge for my services, I was called to see a young woman who had come to Buffalo from the Queen’s colony across the river, full of shame and a story of wrong. She had all the preliminary requirements for membership in a mother’s congress, save a marriage certificate and a ring. Being naturally sympathetic and anxious to show my interest in the fortunes and misfortunes of my patients, I listened to her long story of how it all happened.

"Still, as a sort of reward for my sympathy and services to be rendered, I was informed that the gentleman who was at fault in the matter was willing and ready—nay, anxious—to pay all expenses of her illness. This and the fact that I was practising with all the earnestness, if not the ease, of a ‘real paid doctor, who carries a bag,’ enthused me. How I discovered that the young lady was also suffering with gonorrhea is quite as long and quite as sad as the story of her life. Truly, the gentleman, secure under the protecting folds of the red cross of St. George, was lavish with his favors. I can not truly say that he killed two birds with one stone, but it seemed, figuratively speaking, to amount to that.

"At any rate, I went to work. Twice a day I visited that woman for days and days and days; I irrigated her carefully and conscientiously, and happy was the day when the discharge had ceased and she was rid of one trouble with the other looming up in the near future.

"I saw her, then, every few days after that for a few weeks, sympathizing with her, cheering her, and looking wise. And one morning I called and found that she was free from trouble and that her baby had been born in the early morning hours, without any discomfort to speak of, and that a neighboring physician had been called in after the birth of the baby and had taken charge of the case. While I was there he came in. He was an oldish man, with a supernaturally wise look and ragged whiskers. En passant, always get to windward of a supernaturally wise-looking man who wears his whiskers ragged. He had assumed charge, and he had a snap lock on that case. He could not relinquish the care of that baby nor that woman. He always ‘saw a labor case through,’ he said. And he did. Oh, yes, I would be recompensed for my share of the work.

"He saw the case through, and the gentleman in Canada paid forty dollars, good United States dollars, to my friend with the supernaturally wise look and the ragged whiskers. I was, to use a racing term, among the ‘also rans.’ I felt for a long time like that ‘fore-and-aft’ regiment Kipling wrote about, which was stalked and potted from out the dark by the heathenish, knife-wielding Parthians. That is experience.’"

II. "I’ve had four children, an’ I’m not goin’ to have any more, doctor, not if I can help it, for th’ old man’s got a bad habit of drink, and the rent comin’ due every thirty days, an’ me doin’ a full day’s washin’ every day for six days out of seven, to keep the sheriff out of th’ house. I’m near four months gone now, an’ can you gimme somethin’ to help me?"

"That was the opening statement of her whom I call my judgment patient. I used, in answering her, the words of an old practitioner who had given me the benefit of his years of wisdom in many a comfortable hour’s talk.

"‘You want to get rid of it?’ I asked.

"‘I do,’ she said.

"‘If you will do as I say, I will guarantee that you won’t have any trouble. You go home and live as you
have been living. Take care of yourself. Don't overwork and in five or six months you will be all right.'

"She came of a quick-witted race and she saw the point. She was good-natured about it, too. Two weeks later, I was sent for. It was Sunday, at eleven o'clock in the morning. I found her in bed.

"'It came,' she said, pointing vaguely at the bedclothes. She turned back the coverings and there between her thighs, wrapped in a piece of sheet, lay a foetus, probably four months, dead and dry, the clothes stained and hardened, the foetus attached to the cord, which passed into the vagina.

"'When?' I asked.

"'Last night, about eight o'clock,' she answered. That dead foetus had been there fifteen hours. Then I was strucken with a dash of judgment.

"I covered up the little corpse and sat down and wrote a note to my old doctor friend, asking him to come. He came at once. While awaiting him I gathered the history. The previous Tuesday, 'after a hard day's washing,' she had pains. They continued all Tuesday night and Wednesday. They eased up on Thursday; on Friday there were more, and still more on Saturday. On Saturday afternoon at six o'clock she went to bed, and at eight o'clock the foetus had come away dead. It was attached. She waited an hour or so for the placenta, and as it did not come, she had tugged on the cord, but could not budge it. All Saturday night and early Sunday morning she had at different times tugged at the cord and, failing to get it clear, had sent for me. I had recently delivered a woman in her sixth confinement in the house where she lived. The case was perfectly normal and things went along with neatness and dispatch. This woman was present, and I presume she looked upon me as a sort of a boy wonder.

"When my old doctor friend came, I caused her to repeat the story to him. He saw the condition of affairs and after cutting away the foetus, tried to clean out the uterus with his fingers. He could not, and so finally he curedtted her. She was in anything but good shape. She recovered ultimately, however, under my old doctor friend's care. She probably would not have had I plunged ahead on my own responsibility, and then there would have been all sorts of ugly aspects to the case. I consider that my judgment centre was working full time when I sent for assistance and a man of years and irreproachable standing. He found things as I found them and he assumed charge. It was a charity case and that made me feel content at his compliment: 'You showed great judgment in sending for me in a case like this.'

"III. "The luck case came to me recently with this history: Six weeks previously she had a miscarriage. She was employed on a lake vessel, and believing that everything had come away continued her duties. She flowed considerably for a week. Then the flow lessened for a few days, only to begin again. This kept up for four weeks. She had lost considerable blood, evidently, for she said she was very weak. She went to a doctor in one of the cities at which the boat stopped, and he put pincers in and took out the afterbirth. That was two weeks previous to her visit to me, and she had been flowing most of the time since. She was very anemic and weak. Her legs were edematous and she was, as she expressed it, 'not a bit of good for anything.'

"I found the cervix dilated sufficiently to admit my index finger, and I felt and removed a piece of placenta the size of a silver dollar. The uterus was thoroughly cleaned out and irrigated. Her urine was examined and found to be albuminous. She was instructed to rest, was put on Basham's mixture and strychnine, and she sailed away in her boat on its next trip out a few days later, her duties being assumed by another woman. When the vessel touched Buffalo on its return trip I saw her. She reported that there had not been any flowing whatever, her urine had cleared up, the oedema was about gone, and her lips were getting toward their natural color. She was feeling better, too, and stronger.

"'If there is an element in this case more predominant than another, it is luck. Here was a woman who had every opportunity of entering upon a long and a dangerous siege of sepsis. I don't pretend to figure out how she escaped. I only know that she did, and I attribute it to luck.'

The Air of the "Black Hole of Calcutta."—The Indian Medical Gazette for August says that recent experiments in regard to the processes of respiration show that poisonous leucamines, allied to the alkoide, and the pionama of putrification arise within the body, respiratory oxidation and are expired in a volatile form. The deadly effects of the atmosphere of the "Black Hole" of Calcutta were doubtless largely due to these poisonous leucamines, and not merely to the expired carbonic acid, as has hitherto been supposed.

To Remove the Odor of Iodoform.—Dr. Edwin Ricketts, of Cincinnati (Lancet-Clinic; Buffalo Medical Journal, September), says that to do away with the smell of iodoform that comes to the hands of the surgeon from handling it, he finds that after use of soap and water, a teaspoonful of vinegar (found in every household), rubbed on, does away promptly with the very disagreeable odor.

From a Practical Point of View.—A writer on extrauterine pregnancy, in a contemporary, describes the patient in his first illustrative case as a "widow, though practically married." Some people might consider this description as suggestive of a blemish. On the contrary, it signalizes the tact of its author, for "practice makes perfect."

Indirect Newspaper Advertising.—The Georgia Journal of Medicine and Surgery for August concludes with the following excellent remarks a sensible and praiseworthy editorial against newspaper notices of physicians and their work, such as are commonly seen, we regret to say, nowadays in the sensational journalistic prostitutes of the present day: "It is mere subterfuge to say that we can not help what the reporters do. We certainly can help it if we wish to do so. Let them report the cases we have attended if they wish to. Let them lead our work to the skies if that is their desire, but let us beg of them to mention us as Dr. X, Y, or Z, and not by our proper names. Let us refuse to supply them with our pictures, and to tell them for publication of other great deeds we have done, or volunteer the information of where we were born and where we studied. All that any medical man can do in this age of collective discovery is to act on knowledge he has acquired from others. To take the credit to ourselves in these newspaper puffs of some operation done or cure accomplished is to claim for ourselves individually what belongs by right to the whole profession. Render unto Caesar the things that are Caesar's and an ethical command of undoubted validity."
THE NEW YORK MEDICAL JOURNAL, October 7, 1899.

Original Communications.

A REPORT OF FIVE CASES OF SCOLIOSIS AND ONE CASE OF FLAT FOOT TREATED BY THE TESCHNER METHOD.*

By LOUISE ERICH, M.D., Baltimore.

The five cases of scoliosis described in this report were treated by the system of physical exercise which was originated by Dr. Teschner, of New York. It is founded upon the belief that the want of equilibrium of the muscles on either side of the spinal column in scoliosis is caused by a weakened or rudimentary condition not only of the muscles of the back, but of the muscular system in general; and that to benefit such patients it is therefore necessary that the muscles of the entire body should be developed, educated, and strengthened to the fullest extent.

In all cases which are amenable to treatment, all supporting or immobilizing appliances should be dispensed with, as they interfere with mobility, and thus, by weakening the muscles of the back, chest, and abdomen, counteract the good effects gained by treatment.

All movements should be performed before a mirror in a tightly fitting Jersey suit, so that the slightest error in attitude can be immediately detected by the patient. In this way an habitually correct position is cultivated.

In a paper published in the New York Medical Journal, May 23, 1896, Dr. Teschner says:

"Taking the standpoint that (1) lack of strength and lack of muscular development, (2) habitual faulty position with superimposed weight, and (3) lack of coordinating power or lack of muscular control are the more potent etiological factors in producing deformities, it is and has been my aim, and I believe I have succeeded, in correcting deformities by reversing these conditions—that is, (1) by developing the muscles and their strength; (2) by acquiring an habitually corrected position with superimposed weight; and (3) by educating all the muscles to proper coordination and to complete control.

"A pair of dumb-bells, weighing from half a pound to five pounds, are used in a series of twenty-six exercises for the development of the muscles.

"In addition to the development exercises, I give the patients work with heavy bars and bells at each visit to my office. The weight of the bars and bells, and the number of times that each heavy weight or pair of weights is handled, depend upon the strength, capacity, and upon the endurance of the individual. It is my practice to put each patient to his or her indi-

* Read before the Clinical Society of Baltimore, May 19, 1899.
"When a patient, lying supine upon the floor, raises a heavy bar above the head so that the arms are perpendicular to the floor, the weight of the bar, the position and weight of the body, and the action of the muscles tend to broaden the entire back and shoulders, and a slow downward movement tends to widen the entire chest, and most markedly at the shoulders. The frequent repetition of the upward and downward movement plays an important part in the rapid development of the chest and back. Pushing the bells above the head, swinging them with each hand, separately and with both hands together, raising a bar above the head, standing and lying down, and the exercises before enumerated constitute one day's work.

"As the amount of work performed by a patient depends upon the last previous record of that patient, that record must be improved upon at each succeeding visit, unless there be a good and sufficient reason to the contrary. Most patients can well stand three treatments a week. In mild, habitual cases improvement in deportment is noticed by the patients' relatives and friends and by the patients themselves within the first two weeks. In those cases two months' treatment usually suffices to effect a complete cure. In the more severe cases it is not and can not be expected to attain such rapid results, but a certain appreciable improvement is effected, and the amount of improvement depends upon the persistent continuance of the treatment. Where there is a fixed rotation of long standing, with bony and ligamentous changes, the prospects are not so good: but even in those cases I am sure I have shown considerable improvement in their conditions.

"In closing, I wish to call your attention to certain facts which I have observed in the treatment of my cases, and which should commend this system to the preference of all other methods.

"1. It is rapid, improvement being noticed by the patients, their relatives, and myself within a week or ten days after treatment has begun.

"2. The improvement in general health and the increase of weight.

"3. The wholesome effect upon the nervous system by the cultivation of muscular precision and endurance.

"4. The marked increase in lung capacity.

"5. The beneficial effect upon the heart's action, as shown by the diminished frequency of the pulse and the increase of pulse pressure after each treatment, as shown by Basch's sphygmomanometer.

"6. That all patients continue to improve generally and muscularly long after active treatment has ceased.

"In defending this heavy work against the adverse criticisms of those who might condemn it, either from hearsay knowledge of its baneful effects or from their own observations of athletes who have been 'trained down' for special work, I cite the following facts, viz.:

"The general health has been good. The heart's action has become more vigorous, as shown by the diminished frequency of the pulse and the increased pressure indicated by Basch's sphygmomanometer.

"The weights, chest capacities, chest depths, girths, breadths, and strength tests are generally increased, the abdominal depths are decreased, and the feet, the foundation of correct posture, are improved, inasmuch as all flat feet become shorter and the normal feet grow.

"All this should prove that they are not overworked."

This lengthy quotation gives an accurate description of the method as used by Dr. Teschner. I have followed his directions with two exceptions—viz.:
1. My patients have never, with one exception, used a bar weighing over sixty-one pounds, and rarely dumbbells weighing over twenty-five pounds.

2. They are not required to lift more at each succeeding treatment, and are never permitted to lift an amount which causes discomfort.

As a result, it requires a much longer time to detect improvement than by the more vigorous measures used by Dr. Teschner. My patients do not, as a rule, show marked improvement in less than six weeks. By comparing Dr. Teschner's photographs with my own, it will be found that his patients gain as much in three weeks as mine do in two or three months.

I feel justified in using the method thus modified, however, as I believe that in the end my results are quite as good as Dr. Teschner's, with the advantage of never causing the slightest discomfort at any time and not overworking the patient's heart. On one occasion I had reason to believe that my patient's heart was somewhat overworked after one of the heaviest of the exercises, and I consider it far better to go slowly than

![Fig. 3 — Case II. December 5, 1896.](image)

...to run the slightest risk. And the patients do not progress as slowly as might be imagined from this very lenient manner of conducting treatment. They invariably become very much interested, and there is always a spirit of friendly rivalry among them, each one trying to outdo the others. In fact, they often beg to be allowed to lift more than I am willing to permit. In this way their strength gradually increases day by day, until finally they are able to lift what would ordinarily be considered enormous weights with very little apparent discomfort. Not only this, but they have remarked again and again that about ten minutes after the conclusion of each treatment they are so much stronger that they feel as if it would be possible to do even more than the amount just accomplished, could the treatment be repeated immediately.

**Case I.** — Colored, aged ten years, September 17, 1896. Her mother first noticed a curvature of the spine at four years of age, which became rapidly worse between the seventh and tenth years.

Examination revealed a very severe S-shaped curve, which is well shown in the accompanying photograph. The patient was a small, delicate mulatto, living under all the disadvantages of extreme poverty; but, in spite of this, she improved rapidly between September 17 and October 13, 1896. After this the gain was very much slower; and, although not cured, the deformity was sufficiently reduced at the end of the first year not to be noticeable through her clothing.

When this child came under my care she had been wearing a plaster jacket; and, as she was one of my first patients of this class, I had not the courage to order it removed, as I would surely have done later. This is the only case which I have ever allowed to wear a support of any kind.

**Case II.** — Aged nine years, December 1, 1896. This patient was taken by her father to Dr. Edith Eareckson because of continual pain in her back for two weeks, which became very severe at the end of that time. Dr.  

![Fig. 4 — Case II, May 10, 1897.](image)  

![Fig. 5 — Case IV, February 22, 1898.](image)
Eareckson found a C-shaped curve in the lumbar region, and referred her to me for treatment.

The patient's general health was poor, and she had been suffering from chorea for eleven months. After exercising two months, from December, 1896, until February, 1897, the spinal column became perfectly straight, but there was still a slight inequality in the shoulders and hips, which finally yielded. She was discharged cured in June, 1897, and up to the present time has had no indication of a return.

It is interesting to note in connection with this case that the choreic twitching ceased after a few weeks of treatment. It was not a severe case, it is true, but the twitching was too pronounced to escape the notice of even a casual observer.

Case III.—Aged fourteen years, September 17, 1897. The mother of this child first noticed the curvature of her spine about a year before consulting me. Examination revealed a severe S-shaped curve, convexity right in dorsal, left in lumbar region.

This patient was delicate during childhood, but had good general health after her ninth year. At about five or six years of age she had an attack of rheumatism, leaving a mitral systolic murmur as the result. For this reason it was necessary to use the utmost care in giving the necessary treatment, all heavy exercises being performed by the patient supine upon a table. As a proof that she was not injured by it, her family physician pronounced her heart in better condition at the end than before beginning the treatment.

She improved most rapidly during the first five weeks. After this, although the improvement continued steadily, it was very much more gradual. The change was so great, however, that in eight months the deformity was scarcely perceptible through her clothing. At the end of this time the patient left Baltimore permanently. I can therefore not say what her condition is at present, not having seen her for nearly a year.

Unfortunately, I have no good photographs of this case.

Case IV.—Colored, aged twenty-six years, February 20, 1898. This patient does not recollect when her spinal curvature began, but never felt inconvenienced by it until two years before consulting me. During the said two years she occasionally had pain in the right side, which was diagnosed muscular rheumatism, and treated as such. About six weeks before I saw her this supposed rheumatism became a continuous pain, from which she was not relieved at any time.

Examination revealed a well-marked C-shaped curve, convexity left, in the lumbar region, ilio-costal curve obliterated on the right side; carriage poor.

The patient began treatment February 20, 1898, and continued until she left the city, May 28th. She returned November 23d of the same year, has improved steadily, and does not suffer with pain in the right side any longer.

It is interesting to note that, in addition to curvature of the spine, this patient had perfectly flat feet, which were never free from pain, according to her statement, for ten years before she came under my care. This pain persisted more than three months after she was under treatment for scoliosis, when, to my surprise, it left both feet November 29, 1898. The light foot exercises, which are a part of the Teschner method, had evidently strengthened them sufficiently to remove the pain, although they had not improved the shape at this time.

This happy result suggested the thought: As the cause of scoliosis and flat foot are identical, why not give both the same treatment? I immediately began foot exercises gradually increasing in severity until she was finally able to rise on her toes fifteen times without intermission, holding a hundred-pound bar in her hands, and go through other exercises seated on a high stool with a twenty-five pound dumb-bell suspended from either foot.

The result has been most gratifying. After November 29, 1898, the pain did not return until December 25th. Between December 25, 1898, and January 22, 1899, the feet were painful again at times, although
not so severe as formerly. After January 22d until her last treatment before leaving the city, May 18th, the right foot was absolutely painless, while the left was slightly painful occasionally at long intervals. In addition to this, March 9, 1899, the arches of both feet, especially the right, began to rise, and the improvement in shape has steadily continued since that time.

Case V.—Aged seventeen years, May 10, 1898. The mother of this patient first noticed her deformity at thirteen years of age. From that time until she came under my care she had been constantly under treatment with very little, if any, improvement, according to the statement of her mother.

Examination revealed a slight C-shaped curve, convexity right in dorsal region. Distance from left scapula to vertebrae, two inches; right scapula to vertebrae, three inches. Front view, cartilages of floating ribs more prominent on left than right side.

Right leg half an inch shorter than left. The patient was ordered to wear a half-inch cork sole in her right shoe.

This patient was under my care six weeks, during May and June of 1898, when she left the city for the summer, and returned October 11, 1898, not quite so well as when she left; the curvature increased slightly during her absence. She continued treatment until May 11, 1899, and the result has been gratifying, as shown in the photographs.

ACUTE SUPPURATIVE PROCESSES IN THE FAUCIAL TONSILS.*

By J. L. GOODALE, M. D., BOSTON.

In January, 1899, the writer read before the Boston Society of Medical Sciences a preliminary communication concerning a pathological lesion found in four out of sixteen cases of acute amygdalitis, characterized by the presence of intrafollicular abscesses, occurring as complications of the usual proliferative changes. Since then four additional cases have come under personal observation. In the paper referred to the histological lesions alone were described in detail. The purpose of the present communication is to review the eight cases that have thus far come to hand with regard to their main clinical and pathological phenomena. It was hoped that a study of them might throw some light upon the following subjects:

I. The aetiological relationship of these intrafollicular abscesses to special micro-organisms.

II. Their relationship to peritonsillar inflammation.

III. Their prognostic significance and the possibility of recognizing their presence from clinical appearances.

In each case notes were made with regard to the following points:

1. The clinical history.

2. The macroscopic appearance of the tonsils.

3. The micro-organisms cultivated from the surface of the tonsil previous to excision.

4. The histological phenomena, with special reference to (a) the intensity of the proliferative phenomena, (b) the number and size of the suppurative foci, (c) the amount of fibrinous exudate in the crypts, and finally (d) the number and character of the leucocytes in the interfollicular lymph channels and connective-tissue spaces near the base of the organ.

Technique.—The tonsils, after excision, was immediately cut vertically to its base into a series of slices, each of about five millimetres in thickness. Each slice was laid between two strips of paper in order to preserve its outlines during the process of hardening. The

* Read before the American Laryngological Association at its twenty-first annual congress.
slices were then placed alternately to Zenker's fluid and alcohol. The Zenker specimens were stained by eosin and alkaline methylene blue, which differentiates the various cells better than any other stain known to the writer. The lymphoid cells become deep blue; the endothelial cells of the reticulum and the endothelial cells of the blood-vessels are stained a pale pink; the epithelioid phagocytes are conspicuous through their digestive vacuoles, incorporated substances, and deeper pink cytoplasm. An abscess in the centre of a follicle can be immediately recognized by the bright red color of the cytoplasm of the polynuclear neutrophiles, forming a sharp contrast with the light pink cytoplasm of the surrounding endothelial cells. If, however, alcohol or corrosive hardening be employed in place of Zenker's fluid, the cell outlines are so altered and the selective affinity of the cells for the stain rendered so poor that it is often difficult to recognize small abscesses or even to differentiate the endothelial cells and the epithelioid phagocytes. In staining for bacteria by Gram's method, alcohol hardening remains preferable, since Zenker's specimens do not permit a satisfactory decolorization of their nuclei.

Case I.—A lad, twenty years of age, amygdalectomy of six days' duration, with moderate constitutional disturbance. Tonsils moderately reddened and enlarged with considerable exudate in the crypts. Circumtonsillar region showed no reddening or swelling. Cultures showed streptococci and staphylococci equally abundant. Histologically one of the tonsils exhibited a marked proliferation of the endothelial and lymphoid cells, an occasional small intrafollicular abscess, and a slight amount of fibrinous material in the crypts. The interfollicular lymph channels and the fibrinous-tissue spaces near the base of the tonsil showed an increased number of lymphoid cells and polynuclear eosinophiles, but few or no polynuclear neutrophiles.

Case II.—A lad, twenty years of age, came with acute reddening and swelling of the tonsils, associated with moderate constitutional disturbance of two days' duration. A small amount of exudate was present in the crypts. The peritonsillar region was normal. Cultures showed numerous colonies of *Streptococcus pyogenes*, with a few of *Staphylococcus pyogenes aureus*. Histologically, the tonsil exhibited marked proliferative lesions, with an occasional supplicative focus in the interior of a follicle. A moderate amount of fibrin was present in the crypts. No multinuclear neutrophiles were seen in the interfollicular lymph spaces or in the connective-tissue spaces near the base of the organ.

Case III.—A man, twenty-five years of age, subject to recurrent and severe attacks of amygdalectomy, came with fever, joint pains, and general prostration of two days' duration. The tonsils were enlarged, reddened, with dilated crypts filled with exudate. The peritonsillar region appeared normal. Considerable swelling of the angular cervical lymph glands was present. Cultures showed numerous colonies of *Streptococcus pyogenes*. Histologically, the tonsil exhibited marked proliferation of the endothelial and lymphoid cells, with a considerable number of small intrafollicular abscesses. A moderate amount of fibrin was present in the crypts. No multinuclear neutrophiles were seen in the interfollicular lymph spaces or connective tissue near the base of the tonsil.

Case IV.—A girl, fifteen years of age, with fever and constitutional disturbance of several days' duration, showed considerable reddening and enlargement of tonsils, with exudate in the crypts and several subepithelial white streaks and spots. The circumtonsillar region was normal. Considerable acute cervical lymphadenitis was present. Cultures showed colonies of *Streptococcus pyogenes* and staphylococci. Histologically, the tonsil showed marked proliferative changes, with a moderate number of intrafollicular abscesses. The crypts contained unusual numbers of streptococci and considerable fibrin. The lacunar mucous membrane showed extensive necrosis. No multinuclear neutrophiles were seen in the interfollicular lymph channels or in the connective-tissue spaces near the base of the tonsil.

Case V.—A girl, fifteen years of age, came with fever and sore throat of two days' duration. The right tonsil showed considerable swelling and reddening, with much exudate in the crypts. The circumtonsillar region was normal. Cultures showed colonies of *Streptococcus pyogenes* and staphylococci. Histologically, the tonsil exhibited marked proliferation with numerous small foci of suppuration in the follicles. A moderate amount of fibrin was present in the crypts. No multinuclear neutrophiles were found in the interfollicular lymph spaces or in the efferent lymph channels.

![Fig. 1](Zeis, planar objective, twenty millimetres. No eyepiece. Section through tonsil near base in a case of simple proliferative amygdalectomy. The interfollicular lymph channels and connective-tissue spaces contain small numbers of lymphoid cells, but no multinuclear neutrophiles.)
Case VI.—A boy, twelve years of age, came with constitutional disturbance of four days’ duration, and showed reddened and swollen tonsils, with exudate in the crypts and subepithelial white spots. The peritonsillar region was normal. Cultures showed numerous colonies of Streptococcus pyogenes and staphylococci. Histologically, numerous intrafollicular abscesses were seen, some small and others discharging their contents into the crypts. The crypts contained a large amount of fibrin. No multinuclear neutrophiles were found in the intrafollicular lymph spaces or efferent lymph channels.

The two following cases showed in addition to the amygdaritis also circumtonsillar inflammation:

Case VII.—A man, twenty-five years of age, came with pain in the right tonsillar region of five days’ duration, associated with constitutional disturbance. The right tonsil was much enlarged and reddened, with exudate in the crypts. The circumtonsillar region was reddened and slightly swollen. The right angular cervical lymph glands were enlarged. Cultures showed numerous colonies of Streptococcus pyogenes. Histologically, the tonsil showed numerous foci of suppuration within the follicles, some small, others discharging into the crypts. The efferent lymph channels contained a considerable number of multinuclear neutrophiles in addition to the lymphoid cells and multinuclear eosinophiles ordinarily found there.

Case VIII.—A man, twenty-four years of age, came with pain and swelling in the tonsils of four days’ duration, associated with constitutional disturbance. The circumtonsillar region on the left was reddened but not distinctly bulging. The left tonsil was markedly reddened and swollen, with a moderate amount of exudate in the crypts. In the centre of the exposed surface of the tonsil was a circular excavation about five millimetres in transverse diameter, with ragged, gray, necrotic-looking margins, containing much puriform fetid material. The left cervical lymph glands were swollen. Histologically, the left tonsil showed marked proliferative changes, together with a number of intrafollicular abscesses. In the region corresponding to the macroscopic excavation was a collection of polymuclear neutrophiles, lymphoid and plasma cells, with much unrecognizable detritus extending from the free surface of the tonsil to its base, bordered laterally by the greatly swollen endothelial cells of the reticulum. In the deeper portion of the tonsil, and communicating with the area just described, was a dense collection of multinuclear neutrophiles. The condition appears to be a deeply seated intratonsillar abscess of considerable size, discharging chiefly externally into the throat, but also
suppuration the *Streptococcus pyogenes* was found to be more abundant than forms of staphylococci.

II. The intratonsillar abscesses were found in two cases with and in six cases without circumtonsillar inflammation.

III. The cases represented clinically a severe infection, as shown by the fever, constitutional disturbance, joint pains, and acute cervical lymphadenitis. They unquestionably showed as a whole more disturbance than was present in twenty cases of simple proliferative amygdalectomy observed by the writer.

IV. The tonsils in most cases presented no clinical appearance that would enable one to determine the presence of the intrafollicular abscess. In a few cases subepithelial white spots were seen, which were conjectured to be abscesses situated immediately beneath the epithelium of the exposed surface.

V. Histological phenomena:

1. The suppurative foci were few in some tonsils and numerous in others. They varied often in size in the same specimen, being in some follicles small and barely recognizable, in others occupying most of the interior of the follicle, while in still others the abscesses were seen to have already broken through the lymphoid ring and to have discharged their contents into the adjacent crypts.

2. The amount of fibrous exudate in the crypts was more marked in these cases than generally exists in simple proliferative amygdalectomy.

3. In the six cases not attended by circumtonsillar inflammation, the interfolllicular lymph channels and connective-tissue spaces near the base of the tonsil contained few or no polymorphonuclear neutrophiles. On the other hand, in the two cases accompanied by peritonsillar inflammation the connective-tissue spaces and adjoining reticulum were crowded with polymorphonuclear neutrophiles, and in one of these cases these cells were seen to extend in direct continuity from an abscess situated in the interior of the tonsil toward the base of the organ.

The number of cases thus far observed is too small to justify definite conclusions regarding their etiology or significance. Nevertheless, the following hypotheses suggest themselves as possessing a reasonable degree of probability:

I. The pyogenic infection of the follicles is probably secondary to a previous infection of the crypts by the *Streptococcus pyogenes*. This assumption is based upon the results of the cultures, upon the different age of the abscesses, as observed in the same tonsil, and also upon the fact that a marked proliferative inflammation may exist for several days and the tonsil show on excision only a few incipient abscesses. If the follicular infection were of embolic origin we should expect the abscesses to be more nearly alike in size and to antedate the proliferative inflammation.

II. In the two cases accompanied by circumtonsillar inflammation this complication may have been due to the discharge observed of an abscess into the efferent lymph channels.

My thanks are due to Dr. J. H. Wright, director of the laboratory of the Massachusetts General Hospital, where the histological portion of this work was done.

**TONSILLAR AND CIRCUMTONSILLAR ABSCESS.**

*By GEORGE A. LELAND, M.D., Boston.*

In the spring of 1893 it was my privilege to present a paper to one of the medical societies of Boston on Recurrent Tonsillitis,† in which was elucidated a method of reduction of the tonsils, and especially of the large (or small) lacunal (B. Fraenkel) variety, by the method of “dissection,” first suggested by Hoffmann, who performed the operation by means of a stiff probe. One of the cases there reported was of recurrent abscess, in which for many years the patient, a woman of

* Read before the American Laryngological Association at its twenty-first annual congress.
† *Boston Medical and Surgical Journal*, October 12 and 19, 1893.
thirty or thirty-five years, had suffered untold misery lasting over a period of weeks at every attack. After having reduced the tonsils by the above-mentioned operation to the normal size, at about the regular expected time, another attack occurred. A large crypt, evidently not previously reached, was involved and the tonsil was slightly enlarged in a circumscribed area. This crypt offered some resistance to the right-angled knife, but a small amount of pus was evacuated. Nine hours after a messenger appeared, saying that the old trouble seemed to be coming on. The incision was found but partly open, with a very little pus exuding, the whole region taking on more marked inflammatory action. The incision was enlarged, and with some persuasion the patient allowed me to introduce my finger into her mouth for the ostensible purpose of determining the extent and consistence of the swelling. The opening was found with the tip of the finger, which with some pressure made its way into a cavity as large as a filbert, whose walls were hard and resisting, like those of a small rubber ball. On withdrawing the finger, the opening was torn downward as much as possible and thus greatly enlarged, and the contents of the cavity thoroughly evacuated, much to the distress of the patient, it may be added.

Judging from her former experiences, she expected several weeks of dire illness, and insisted that she be visited on the following morning; when, instead of finding her in bed with saliva drooling from open mouth, muffled voice, and great constitutional disturbance, she was up and about, attending to her household duties as usual, having slept well during the night, and very comfortable. And she has not had another attack from that day to this—i.e., since May 31, 1893.

The experience in this case has led me to use this instrument of Nature, the sterilized index finger, to make many clinical observations in cases of tonsillar or circumtonsillar suppuration, with observations which, in the absence of autopsies in such cases, where death does not often occur and where the lesions are in such a locality that careful dissection can not easily be made, not only appear to be interesting, but which may be turned to valuable account.

This method of digital exploration has thrown some light on the etiology of this affection; it seems to show conclusively that circumtonsillar inflammation most frequently starts from within the tonsil, in one or more of the lacunae, and is an extension of the suppurative process in the direction of the least resistance, as is the case with abscess formation in other localities. This conclusion I had arrived at some years ago, and am glad to see it confirmed by Moritz Schmidt in his edition of 1897,* lately come to hand, where he says that, according to his experience, it (peritonsillitis) arises almost only from tonsil plugs; that these take on suppuration from streptococcus infection, and that the products find their way outward into the peritonsillar tissue.

This process is further elucidated by Dr. G. Finder, of Berlin,* in his article Zur pathologische Anatomie der Tonsille, when he shows that by swelling of the epithelial lining of one or more of the crypts and by other changes the outlet may be closed, so that it may not be found even by microscopic examination; that the contents of the crypt, consisting of epithelia, lymph corpuscles, mucus, and micro-organisms, go on increasing till the crypt becomes an encysted abscess. The disease first appears then as a tonsillar abscess, which may burst or be evacuated inward into the faucial space, or it may extend outward into the peritonsillar tissues.

In the case mentioned at the beginning of this paper, the extreme severity and long duration of the attack, extending through a period of many weeks, make it certain that from tonsillar it became circumtonsillar, and this course is described by A. Rosenberg.†

Formerly, and even now, exposure to cold, rheumatism, etc., were, and are, mentioned by most English-speaking writers as the principal cause of this disease, but since bacteriology has opened up its new fields and given new aspects to pathological processes the septic origin is recognized as the proper explanation and the former causes put down as simply reducing the resistance of the tissues.

Now, by the use of the finger tip after the tonsil has been split by the sickle knife, the enlarged and distended crypt can be frequently made out and the sinus followed upward and outward through the tonsil into the circumtonsillar cavity, which may be found either to be small above it or enlarged downward outside of the tonsil and even below it. And I have frequently been able to determine the exact size of the abscess cavity in this way; and in large ones to pass the tip of the finger down outside of the tonsil to its lowest limit; and then, in order to give proper exit for the pus at its lowest level, to complete the operation by tearing through the tonsil inward into the throat, thus passing the finger nearly around and through the organ. Of course, if the cavity has not begun to bag downward, such a large wound is not necessary, the exit being made only large enough to empty the abscesses from the bottom. I have tried a blunt stiff probe for this purpose, but have not been so well pleased with it.

After having repeatedly punctured the velum palati, according to the universally-recommended method, many times in the vain search for pus (in one case twelve times), much to my own embarrassment and the patient’s discomfort, the success of this method in finding the pocket, be it small or large, has given me the great-

---

* Die Krankheiten der oberen Luftwege, p. 289.
est satisfaction. With it there is no danger of wounding the branch of the ascending pharyngeal artery in the anterior pillar of the fauces, the carotid lying outside of the abscess cavity not being within reach.* To be sure, this method is productive of a great deal of pain, though its addition to that already being suffered by the patient may not be great. And when desirable or demanded by the patient, a whiff of ether may be given, in the proper (Rose) position, to relaxation of the jaws (an important consideration), when the operation may be conducted without pain even before complete primary anesthesia has been attained.

Another advantage may be alleged for this method—viz., that it drains the abscess from the bottom. The usually advocated method of opening at the place of pointing, even though the incision be enlarged by the probe, as advocated by Bosworth and others, or by the finger, as mentioned by Stoerk (which Max Tornier says is certainly a very painful procedure †), must frequently, if not always, open the cavity at or near the top. This operation may sometimes leave an objectionable scar, but especially does it leave problematical the complete granulation of the cavity from the bottom, which may be an aetiological factor in the recurrence of this distressing affection. In the cases operated upon which I have been able to follow there has been no recurrence, and though their number is too small for definite conclusions, and the time since operation too short, still it is a satisfaction that with some the usual period has elapsed without an attack.

Another advantage possessed by this method is the very quick recovery. True, the evacuation of pus is the turning point in almost every case by whatever method; but, as a rule, the patients thus operated upon are able to swallow liquids in six hours and solids in twelve, and some of them have been well enough to be discharged from the hospital the next day. This saving of time is of much value to those in all walks of life where time is of importance, not to mention the suffering entailed on waiting for several days or even weeks for the abscess to burst, when numerous and frequent proddings have failed to locate pus.

A newsboy, sixteen or eighteen years of age, came to the clinic last fall presenting the unmistakable facies and attitude of a sufferer from this disease. He was a Hebrew from the White Czar's dominions, and so prone to make a great disturbance. The tonsil was quickly split under illumination, and the patient placed in a firm chair. One assistant was stationed at each extremity to be ready to hold it firmly, and one behind to get on to his shoulders and hold him in the chair. I then got his head in chancery, and, the mouth being held open with a gag, the finger was made to thoroughly traverse the course of the suppuration and was then torn out through the tonsil. Considerable pus and blood were evacuated. After gargling freely with hot water, he left the clinic expressing himself as much more comfortable.

The second morning after I met a lively boy on the street corner, unrecognizable as the patient of two days before. He came up and said, "Good morning, doctor. Throat all right to-day. Have a paper?"

A student, G. T. S., twenty-three years of age, came to my office on November 10, 1897, with the unmistakable attitude of fascial phlegmon, this being the sixth attack since he was fourteen years old. The previous March an attack involved both tonsils, each lasting a week. Both tonsils were found enlarged, the left, the seat of the greatest swelling, with pus bathing the inner surface and exuding from the lacunae. The attack began three days before; the patient was much reduced, and the jaws could be but very slightly separated. Hence the left knife was used to enter the tonsil, and the right knife to enter this incision and to cut upward into the substance of the velum between the pillars, where it seemed to enter a cavity, from which and from the tonsil a moderate amount of pus was evacuated. Instead of waiting two or three days for the subsidence of some of the swelling, as advised, he appeared the next day to have it thoroughly opened up. The tonsil was then split from top to bottom, and the left index finger introduced into the incision passed upward and outward into a large cavity which extended downward outside of the tonsil, seemingly below its inferior boundary. The finger was then twisted inward through the substance of the tonsil into the throat and all the tissues torn through down to the bottom of the cavity. Haemorrhage was quite copious, perhaps two or three ounces, and from four to six drachms of pus evacuated.

The patient expressed himself as much pleased that for once the abscess had been thoroughly opened, saying that it never had been before, though it had often been punctured and although it was somewhat severe at the moment, that he felt immediate relief and could open the mouth much wider than before.

On the fourth day after he again appeared, the change in his appearance being most marked, and said that he had never had such a quick recovery. The other tonsil had also subsided. On the ninth day after the operation the cavity was nearly obliterated, it having been treated by application of equal parts of tincture of iodine and glycerin. Sometimes this after-treatment is of service to insure healing from the bottom, the application being made with a stiff cotton-wound probe well into the bottom of the wound.

A gentleman of forty-five (?) years of age, in a hotel near my office, had an alveolar abscess from a dead tooth. His dentist, in treating it, found also antrum disease. During a course of syringing of the antrum by the dentist a circumtonsillar abscess developed. After a week or ten days of extreme suffering from pain, starvation, and insomnia, till he was a perfect wreck, I was called. The faucial space was nearly obliterated by the swelling of a right-sided peritonsillar abscess. The jaws could scarcely be separated. Under illumination the sickle knife evacuated through the tonsil a large quantity of foetid pus. The finger was then introduced, and the cavity extending far outside of the tonsil was torn through from the bottom. He slept considerably that night, went out to get a shave

---

† Article on Acute Pharyngitis, Burnett's *System*, vol. ii, p. 264.
the next day, and rapidly recovered; and a month afterward the parts had healed so that there was no sign of the disease or operation; and it sometimes seems strange how so much destruction can be so completely repaired.

Sometimes, after passing through the tonsil, the finger brings up against a tensely filled cavity, which it is impossible to enter; this, however, may often be opened in the same way the next day or so, or the probe point of the knife can be forced through by pressing it upward and outward. This starts the pus, which makes subsequent procedure easy, and the pus may be reached before the extreme swelling usually seen is attained. One case of fatal termination should be mentioned in this connection:

Five or six years ago I was called in consultation to a case of this nature of extremely aggravated type in a large, strong Irishman, who had suffered about a week. With his attending physician’s help he was etherized, the tonsil split, and the finger introduced. It was impossible to break through the abscess wall. He was much more comfortable afterward, probably from the depletion and reduction of the tonsillar swelling. Against orders, he was removed from his boarding house to a suburb, out of our reach. The next night, twenty-four hours after our operation, he retired, expressing himself as very comfortable and thankful for what had been done. About an hour afterward a relation entered his chamber and found him breathing heavily. Five physicians were summoned: death ensued before they arrived. There was no autopsy. I am perfectly confident, in the light of subsequent cases, that the sac could have been entered the morning after we saw him.

In a series of cases at the hospital treated by this method, the house officer, Dr. Fitzgerald, finds that if opened at the start they were discharged as “well” on the following day, and that other cases averaged two days; while in those cases treated by the old method on other services, four opened spontaneously, and one case is mentioned where, after prodding by the old method, it yet opened spontaneously—all after days of tedious and painful waiting.

It is not asserted for this method that it is new or original, for one of our older surgeons, Dr. W. P. Boles, told one of my volunteer assistants that the surgeons of fifty years ago always used to open circum-tonsillar abscesses with the finger, in all likelihood not through the tonsil, however; but it is maintained that it is thorough, that it can be made painless under slight general anesthesia, that the opening is made through diseased tissue, that the pus tract and cavity can be found earlier than by the old methods, and that thus much time and suffering are saved.

The St. Louis Medical Society.—At the last regular meeting, on Saturday evening, September 30th, Dr. H. C. Fairbrother reported a case of syphilitic meningitis, and Dr. John Young Brown presented specimens illustrating some points in the pathology of appendicitis.

THEAMEBACILIATAINDISEASE.*

By HENRY GERON GRAHAM, M. D.,
CHICAGO.

(Concluded from page 492.)

We have seen in the experiment with the infusion of potato, which had become strongly alkaline, that the ovules kept indefinitely. Such ovules are not affected by a saturated solution of potassium hydrate, but are broken up into minute lustrous bodies by chemically pure sulphuric acid.

On being taken into the mouth in drinking water, most of the amebe, of course, pass out again with the excreta, but it is possible, from their constant presence in water, that some few may be at all times present in the tissues even in health.

Once in the mouth, the structures the amebe might successively enter are the ducts of Rivini, Wharton’s duct, and Stenson’s duct, the ducts of the serous glands at the base of the tongue, and the orifices leading to the follicles in the substance of the tonsil. Their transitory passage through the mouth renders it improbable that they should enter any of these, though possibly they may do so. The same is true of the Eustachian tube, which water ordinarily does not reach, but here, too, there are probably exceptions. Thus, in the case of a little girl who had had an attack of dysentery, suppuration of one middle ear immediately followed and was attributed to the general infection.

After the Eustachian tube, the next large orifice to be encountered would be the larynx, and, as the ovules are sometimes found in the mucous-pus coming from the larger bronchial tubes, it is possible they may enter here. The next large orifice would be that leading to the ductus communis choledochus. It is possible that this organism may find its way into the canal of Wir- sung, but it is almost certain that it frequently enters the hepatic and cystic ducts, especially the former. Then come the solitary glands and Peyer’s patches, which are the gateway for the entrance of the typhoid bacillus. We should also expect the appendix vermiformis to be a favorite resort for the amebe.

In order to ascertain whether or not an organism measuring on an average about ten to twenty-five micro-millimetres in diameter may enter one of these glands, it is necessary to look into their structure. Gray says: “They (the solitary glands) are now recognized as lymph follicles,” and that they are “closely packed with lymph corpuscles.” From Landois and Sterling: “They (the solitary glands) consist of small masses of adenoid tissue loaded with leucocytes.... Peyer’s

* In the first part of Dr. Graham’s article, published last week, the word *ellaria* was erroneously printed instead of *elativa*. These further errors are to be noted: Page 478, second column, twenty-second line from the foot, for “probosces” read filament; page 480, second column, seventeenth line from the foot, for “backed” read racked; page 481, second column, ninth line from the foot, omit “almost.”
glands, or agminated glands, consist of groups of lymph follicles like the foregoing. The masses are often more or less fused together, their bases lie in the submucosa, while their summits project into the mucosa, where they are covered merely by the columnar epithelium of the intestine. The lymph corpuscles often pass between the epithelial cells. That is sufficient for our purpose. An ameba can pass through a narrower channel than that through which a leucocyte can pass. While amoebae are often larger than a leucocyte, most of them, as they are found in hydrant water, are smaller, and the cilia would enable an ameba to escape where a leucocyte of the same size would be held fast. Their great penetrative power would probably enable the largest amœba under favorable conditions to enter the solitary glands and Peyer's patches. Once inside, the same thing would happen that always happens when numbers of them are found within an inclosure. The eotosarc of the more fragile would burst, setting the contents free, the hardier individuals passing on with the lymph current. This would leave large numbers of typhoid bacilli free within the solitary glands and Peyer's patches. Repeated experiments have shown that when this bacillus is injected beneath the skin or into the peritoneal cavity of animals, inflammation results, an abscess forms, and suppuration is followed by an ulcer. This is exactly what occurs in the solitary and agminated glands in typhoid fever. But in the one case the bacilli are transferred from a culture medium into tissue where the surroundings are unfavorable, while in the other the bacill pass directly from the fluid of one host into the fluid of another host, in both of which they have repeatedly been found alive. From the solitary and agminated glands they are quickly disseminated throughout the lymphatic and vascular systems, thus making the infection very speedily general.

From a comparison it is seen that we could no more expect to nourish a patient by injecting a little gruel beneath the skin than we could hope to produce a general infection from the typhoid bacillus by the same methods.

The amœbe once within the solitary glands have no difficulty in reaching the entire lymphatic system, for "the interspaces of the retiform tissue are continuous with larger lymph spaces at the base of the gland through which they communicate with the lactic system." (Gray.) That this is the principal source from which they are disseminated is shown by the early infection of the mesenteric glands. "It penetrates at first into the follicles and Peyer's patches, and thence goes on into the mesenteric glands, the blood current, the spleen, and other organs." (Strümpell.)

The susceptibility of the eotosarc of the amœba to mechanical pressure, varying as it does from one extreme, where it is burst by the dropping of a cover slip upon it, to the opposite extreme, where it can not be ruptured by pressing it between a slide and cover slip, would seem to indicate that while perhaps most are ruptured external to the alimentary canal, near the point of exit from it, some may reach the integument, and that others are ruptured at intermediate distances.

It is probable that a few may reach the skin, and, being unable to pass through it, as they were unable to pass through the external integument of the larva, rupture here, setting free the bacilli, which produce a local inflammation resulting in a circumscribed inflammatory area. Ovules of the amœba and bacilli have been found in the same rose spot. It is therefore more than possible that a few individuals that have succeeded in penetrating the corium to a greater depth than the others may be the cause of the rose spots seen in typhoid fever. When the eotosarc bursts and the bacilli are set free, the latter would naturally be found in a body. "They are found for the most part lying together in little clumps—foci of bacilli—in the organs." (Strümpell.) "The bacilli are not uniformly distributed, but usually lie in clumps in the tissue." (Ziegler.)

At the point where the eotosarc bursts we would also expect to find large numbers of ovules. "In the first of these localities, solitary and agminated follicles, they—the typhoid bacilli or their spores—cause an inflammatory infiltration of the mucosa and submucosa that is extraordinarily rich in cells." (Ziegler.)

"There is a great increase and accumulation of cells of the lymph tissue" in Peyer's patches and in the solitary glands. "The cells have all the characters of ordinary lymph corpuscles. Some of them, however, are larger, epithelioid, and contain several nuclei." (Osler.)

The first is a good description of the ovules of the amœba, the second of the amœba itself in its resting stage.

Why most individuals escape infection and the few are attacked is not more difficult to explain than why one larva should be attacked and the many go free in a medium teeming with amœba; or why one microcodon in a thousand should meet its death in so extraordinary a manner and the others escape, although the same danger constantly threatened.

In this case of typhoid fever, a drop of blood removed from the ear was placed in sterilized hay infusion. In this there developed large numbers of the amœba. In a control experiment, with the same hay infusion, no amœba developed.

Malaria.—In a number of cases where men employed on the drainage canal contracted malaria, ovules of the amœba were found in the blood. Here two kinds of amœba were usually to be found. In what appeared the less important variety, the ovule was large, circular, with dotted lines radiating from the centre, and other similar lines in the form of concentric circles intersecting the first series of lines. As differentiation progressed, the individual embryos could be made out, the two series of lines forming the lines of cleavage. As the agglutinating substance which held the mass intact
disappeared the embryos were set free, and could not then be distinguished from monococci, save that some of the latter are more active. These embryos were found inside the red blood-corporcles and free in the blood current. Their color was similar to that of the red blood-corporcles, from which it was probably derived. However, similar monads found in hydrant water often present this same red appearance.

The other organism, and apparently the more important of the two, found in these cases, was the Amoebe ciliata. This organism carried with it the monococcus as a parasite. These monococci were very actively motile, and, while some of them were found inside the red blood-corporcles, most of them were free in the blood plasma. The cocci multiplied within their host, for numerous diplococci, some of them exceedingly active, were to be seen. On entering the corpuscle they pass direct to the centre, leaving in their wake a track free from the coloring matter of the corpuscle, so that when two or more enter, it can be seen what part of the corpuscle each has traversed. Usually all will be found at or near the centre, where they remain until the corpuscle is broken up.

These micrococci are probably the same that can, by successive cultivation on proper media—e.g., the lymphatic and vascular fluids—be made so virulent as to produce septicaemia. This would be suggested by:

(a) These cocci are facultative anaerobes, having subsisted for over seven months shut in from air and light, many individuals at the end of that time being as active as ever.

(b) They may form short chains in imitation of the streptococcus.

(c) Most of them, when growing as anaerobes, form circular groups in imitation of the staphylococcus.

(d) The culture medium has a marked influence upon the morphology of these water organisms. The same is probably true of the degree of virulence of the pathogenic forms.

(e) Cases of severe malarial infection present some symptoms common to both malaria and septicaemia—mixed infection. It is possible that the principal difference between malaria and septicaemia is that the monococcus grown in the amoeba is not nearly so virulent as the same micro-organism grown in human blood. It is probable that the amoeba is in itself a comparatively benign organism, but that it owes its importance as a morbid agent to the parasite it carries.

(f) Organisms that in hydrant water are actively motile are, as a rule, when found in the blood, less so or non-motile. In this respect they often resemble the same organism as it is seen in very cold or in hot water.

(g) This coccus being constantly present in water, it follows that so small an organism is constant in the urine, for the frustules of various diatoms, organisms many times larger than this coccus, are frequently present in the urine. It multiplies very rapidly if the urine, after being voided, has access to air. But we have seen, too, in the above-mentioned experiment that it multiplies very rapidly if it does not have access to air. This coccus is probably identical with the Micrococcus ureae, the larger size of the latter being due to the peculiar properties of the culture medium.

**Chronic Hypertrrophic Rhinitis.**—If the nasal mucous membrane is copiously irrigated with an irritating solution, so as to bring away large numbers of epithelial cells, among the latter will be found embryonic forms of the amoeba. It is probable they are in some degree responsible for the hypertrophy. This condition is often a sequence to malarial infection.

**Dropesy.**—In a little boy who died at the age of seven from a general dropy, in ascorbic acid removed an hour before death were found some ovaules of this amoeba.

**Pneumonia.**—If a small circumscribed abscess forms under the mucous membrane of the cheek or lip as the result of a cold, the pus from it usually contains a diplococcus. As the result of an insignificant trauma or of a cold, there is a slight abrasion or fissure in the mucous membrane. From what we now know of its great penetrative power, it is probable that an amoeba enters, and at some distance from the surface the ectosarc bursts, setting the micrococi free. They have found a new and more favorable environment, begin to multiply rapidly, and form diplococci. They are exceedingly active and are not long in setting up a focus of suppuration. These diplococci appear very like Fränkel’s pneumococcus minus the capsule. How does the pneumococcus obtain its capsule? We have seen how in all probability the typhoid bacillus develops the capsule that makes it so highly refractive by long residence as a parasite within its host. The probability is that Fränkel’s pneumococcus obtains its capsule in the same way. It is well known that in ordinary culture media it is without a capsule. When two or more of these diplococci without the capsule are united they look exactly like the short chains formed by the diplococci grown as anaerobes and which have been referred to above. This capsule is not found in all cases of pneumonia, and when found is probably seen in diplococci that have not long been set free by their former host. It is scarcely necessary to repeat that the monococcus or diplococcus, which probably becomes the pneumococcus, is a frequent parasite of the Amoebe ciliata.

Staphylococci and streptococci are often present in pneumonia, and are frequently the cause of death in cases that result fatally. It is not difficult to account for their presence later on in the attack if the pneumococcus has but to lose its capsule to become the staphylococcus or the streptococcus.

It is not surprising that a number of germs have at various times been brought forward as the specific cause of pneumonia, seeing that the parasites in a large number of amoebae are often protean in their morphology. Thus the bacillus of Friedländer and of Frobenius was
at one time believed to be the exciting cause. This bacillus "has also been found in the nasal secretion and in inflammations of the middle ear." (Ziegler.) It is probable that the amœba must not only invade the pulmonary tissues, but that they must reach them in sufficient force in order to set up a true pneumonia. Where a few reach the middle ear, circumscripted, local inflammation follows; had they passed on to the appendix vermiformis, there would have been an appendicitis.

In a typical case of pneumonia that occurred in the winter of 1897 and 1898, during convalescence an abscess formed on the plantar surface of the foot—meta-

In the pus that escaped through an incision was found the pneumococci of Fränkel.

In a recent case of pneumonia, the amœba was found in the urine.

**Malignant Óedema.**—In a case of malignant œdema, the amœba was found in the blood and in the urine. The parasite was probably the bacillus of malignant œdema and formed spores. Only once were these spores seen when every bacillus seemed to contain one. The spore was not in the centre, but in the end of the bacillus, and was stained red, the bacillus blue.

**Purpura Êemorrhagica.**—The finest specimens of the amœba seen in any disease were found in the urine in a case of purpura hæmorrhagica. This was really almost pure blood, and the quantity, together with the concentration of what amœba it contained into a few drops, probably accounts for the large number seen. But they were at the same time larger than the average amœba as it is seen in the fluids of the body. A saturated solution of potassium hydrate was used to destroy the ectosarc. This was also used as a means of differentiation to distinguish amœba from leucocyte. The amœbe possessed a distinct capsule, elliptical in form, and would burst on coming in contact with the potassium hydrate solution and disappear, leaving the contents to be dispersed. The leucocyte was irregularly rounded, composed of a stroma inclosing irregular spaces, and after it had been in contact with the same solution for some time, would suddenly and evenly expand, expel a portion of its contents, and as suddenly again resume its former dimensions, the stroma remaining intact.

When the ectosarc of an amœba was destroyed, a mass of bacilli large enough to have almost filled the ectosarc, and held together by an agglutinating substance, was exposed. There was a constant, rapid, vibratory motion of the entire mass of bacilli, such as is sometimes seen within amœbe found in hydrant water. The bacilli were held in such a compact body that individual movement was impossible save at one end of the mass where the agglutinating substance was deficient. When there was a cleavage of the mass resulting in its division into two or more parts, each part would continue the same vibratory motion. These bacilli contained no spores. While some of the amœbe contained a bundle of bacilli, in many there were only a few. Some of these contained spores and were stained—the spores red, the bacilli blue. This last was the same bacillus as that found in the case of malignant œdema.

Many bacilli were floating free in the urine, or blood and urine, and these masses of bacilli in their grouping presented the appearance characteristic of the Bacillus proteus vulgaris. They contained no spores.

This same amœba and bacillus were found in the vomited matter which was tinged with blood. In some drops of blood removed through a puncture in the skin, ovules of the amœba and bacilli were found. The integument was covered with minute hemorrhagic spots. These were evidently produced in much the same way as the rose spots in typhoid fever, there being probably this difference: That in typhoid fever the parasite is the typhoid bacillus, and in purpura it is the Bacillus proteus vulgaris.

The great prostration, the high range of temperature, which at one time reached 105° F., the great loss of blood with which the urine, faces, and vomited matter were tinged, and the multiple hemorrhagic lesions in the skin, were all indicative of the intensity of the infection. Yet shortly after the appearance of the hemorrhagic spots convalescence set in, and in the course of a week was almost complete. This would be anticipated where the infection is due to some benign organism, such as the Bacillus proteus vulgaris, which some hold is never pathogenic.

If set free in large numbers in the blood, there is abundant evidence to show that this organism would for a short time, at least, produce considerable prostration.

In this case the question arises, Is the large mass of bacilli held in so compact a body, that is so large as to almost fill the ectosarc of the amœba, merely a bundle of parasites, or are they a part in the cycle of existence of the amœba itself, just as a member of the family Ranidae is a tadpole before it is a frog?

In hydrant water there is sometimes found such a dense, compact mass of seething, writhing, wriggling bacilli that the wonder is how it is possible they should be so bunched, and at a short distance away not a single bacillus be found. A compact body of bacilli, presenting much the same appearance and possessing a similar movement, is sometimes seen within the bodies of amœba found in hydrant water. Possibly this bacillus is a form representing a stage in the development of the amœba itself, a part in its cycle of existence.

An almost parallel case would be that of an organism mentioned by Catlow that is found in the marshes along a portion of the coast of Norway. Such an hypothesis would account for the presence of the bacilli in the specimens above referred to. These bacilli, it should be added, were quite lustrous.

If it is true that a monad—spore of an amœba—may become a bacillus and the bacillus an amœba, it would
follow that for every specific disease there would have to be a specific amoeba, where an amoeba is the direct or indirect cause of such disease.

**Dysentery.**—In a case of dysentery, an elongated amoeba, with a flagellum at either extremity, was found in the stools. This is the form of the *Ameba ciliata* which immediately precedes that of the perfect organism and corresponds to the chrysalis of an insect. With the amoeba were found bacilli and spirilli in abundance. No doubt many of these were carried into the alimentary canal by the amoeba.

Lamb, as long ago as 1859, recognized this organism as being a principal cause of dysentery. Since then his findings have been confirmed by Lösch, Kartulis, Musser, and others. Its relation to dysentery is now well recognized. It probably owes its importance here as a morbid agent more to the germs it carries with it than to any pathogenic properties possessed by itself.

Osler is here quoted to show that it is not confined to the intestinal tract: “In 1890 I reported a case of dysentery with abscess of the liver, originating in Panama, in which the amoeba were found in the stools and in the pus from the abscess. . . . The lesions are found in the large intestine, sometimes in the lower portion of the ileum. Abscess of the liver is a common sequence. Perforation into the right lung is not infrequent.” (Osler’s *Practice*, 1899.)

When diarrhoea occurs in typhoid fever, it is probably owing to numerous amoebae with their parasites, some of which are probably spirilli, that chance to remain in the alimentary canal. When no diarrhoea is present, it is probably because all amoebae have left the alimentary canal. In the small larva, of the score or more of amoebae present, not one had remained within the alimentary tract.

**The Widal Test.**—When typhoid bacilli are brought in contact with serum from a patient suffering from typhoid fever, the bacilli form agglutinated masses. Here the very same thing happens to the typhoid bacilli that happened to the bacilli found within the amoeba in the case of purpura. The inference is that the agglutination is caused by some substance within the ectosarc of the amoeba. This is probably the fluid contents of the ectosarc—the fluid portion of the endosarc. After the death of the amoeba, the ectosarc disappears, the fluid escapes, and probably undergone a change similar to that which takes place in protoplasm when it dies. Under this changed condition, we should expect this agglutinating power to be increased.

The amount of such fluid in the blood of a typhoid-fever patient is probably considerable. If it were in proportion to that found in the larva it would be very large, and in the case of the micrococcid it was almost equal to the mass of the host.

Some would find its way into the blood with the bursting of the ectosarc of the first amoeba. This would continue until it would reach its maximum, which would probably be when the first rose spots appear, for this would indicate that some of the most resistant had succumbed. We should expect the test to be at its best about this time or a little later. So, too, blood procured in the evening, when the temperature is higher and when more fluid is set free, would probably possess this agglutinating power to a greater degree than that procured in the morning. Finally, if this is the cause of the agglutination, the same phenomena should be witnessed with blood obtained from persons suffering from other acute diseases in which the amoeba is found in large numbers.

**Résumé.**—From what is now known of this organism, the following may be formulated: 1. The type of disease which the *Ameba ciliata* will produce is determined by:

(a) The kind of parasite it carries.

(b) The tissue or organ it invades.

(c) Its distribution over a large, or concentration in a small area.

(a) If the parasite is the typhoid bacillus, there is typhoid fever; if the *Bacillus proteus vulgaris*, purpura hemorrhagica; if a certain spirillum, dysentery; if the pneumococcus of Frankel, pneumonia, etc.

(b) The position often assumed, that for each region or tissue of the body affected, with accompanying distinctive symptoms there is a specific infecting organism, is probably untenable. In pneumonia, for instance, the type of disease is determined by the fact that the pulmonary tissues are invaded. Had there been an invasion of some other tissue or organ by the same organism, carrying the same parasite, the type of disease would have been determined by the tissue or organ invaded—e.g., abscess of the middle ear or of the liver, appendicitis, meningitis, etc.

(c) The infection produced by the amoeba is mild or severe, according as they are diffused throughout the entire system or concentrated in a small area. Herein lies the chief danger from an invasion by these organisms, for it is their habit to often move in “schools,” very much as an invading army enters the enemy’s country—in a body. Where there is even distribution throughout the system by means of the lymph and blood currents, without concentration at any one point, there results malaria or malignant oedema, according to the parasite carried. With concentration, for instance, in the pulmonary tissues, there would result pneumonia. Pneumonia, it will be remembered, has been produced in the lower animals by injecting into the pulmonary tissues inert substances. Here the foreign body acted as an irritant, resulting in obstruction of the lung, principally by the animal’s own tissues.

3. The *Ameba ciliata* is probably in itself of little or no pathological significance.

3. Its importance as a morbid agent is due to:

(a) The protection afforded its contents from the
action of destructive agents, whether mechanical, chemical, or thermal.

(b) Its power to penetrate tissues and organs distant from the alimentary canal and that passive agents can not reach.

Its penetrative powers are seen to best advantage in the study of the Amoeba ciliata in its relations to other higher water organisms in which the tissues of both host and parasite, or invader, are transparent.

4. Where there is an invasion of a vital organ, resulting in interference with its normal function, the disease becomes very much complicated. To the poison from without is added the poison generated within, which would have been thrown off but for such interference.

Bouchard has estimated that in two days four hours a healthy man will excrete by the kidneys alone sufficient poison to have killed him but for its elimination. The amebo and its products are excreted principally by the kidneys.

5. Some of the white corpuscles in the blood, and some of the pus corpuscles in the urine, in a number of acute infectious diseases, and in some subacute diseases, are often nothing more nor less than the ovules of this same amebo.

In this connection it is pertinent to suggest that a probable function of the spleen is the arrest and destruction of embryonic forms of the innumerable minute organisms with which all natural fresh waters abound.

Subsequent investigation will probably discover slight errors, but will no doubt confirm in the main what has been here foreshadowed.

264 South Halsted Street.

PURPURA RHEUMATICA.

REMARKS. TWO CASES IN THE EXTREMES OF LIFE.

By W. L. JOHNSON, M. D.,
DEPARTMENT OF SKIN DISEASES AND STYPHYLES
AND ASSISTANT IN CHILDREN'S CLINIC, ST. JOHN'S HOSPITAL DISPENSARY,
ST. LOUIS.

The etiology of purpura (in general) is not at all determined; the pathology is not yet clear. Writers are agreed that hemorrhages may be due to rhexis in some cases, in others to diapedesis. Many have recorded their failures in determining lesions in the walls of the blood-vessels. Unna and Sack, however, by certain methods of examination have found ruptures of the walls of the veins.

Babes has found hyaline, Wilson Stewart and Fox lardaceous, degeneration of the walls of the blood-vessels in purpuric conditions; but Unna maintains that these degenerative changes would tend to restrain rather than to further hemorrhages. Amyloid degeneration and desquamative endarteritis have been reported.

Recently micro-organisms have been sought in the blood, its vessels, and other tissues, with results not uniform. Even when found, the bacteria can not be charged with being the cause.

The toxins they produce are credited, and probably rightly, with producing such changes in either the walls of the vessels or in the blood as to favor rupture in the one case or diapedesis in the other.

The mechanical causes are many. For instance, where there is local obstruction or great cardiac weakness purpuric extravasations are not uncommon. Witness the occasional purpuric spots from tight garters or from varicosities. The purpura of the senile—in which there are no other symptoms—is considered by one writer as in a sense mechanical, but yet dependent upon changes in the vascular walls, these changes being due to a long-existing toxic disturbance. That is to say, were it not for these changes, the senile heart, the retarded venous current, would not of themselves produce the purpura.

Lack of support of the elastic tissue of the skin, as found in the marasmic infant or the victim of a wasting disease, is a factor seemingly supported by Unna's observation that these ruptures are found at the point of least resistance—namely, at the junction of the superficial part of the subcutaneous tissue with the lower part of the cutis. That nervous influences share not a minor part is evident.

In the Lancet, March 17, 1888, we find mention of a case of purpura hemorrhagica twice occurring from mental shock in a subject who had never before manifested such a tendency, and Dr. De Smet, of Brussels, whose case it was, reports other skin diseases following mental shock. Dr. Weir Mitchell has reported purpura occurring at the site of neuralgia; and Strauss, cases having extravasations in the course of tabetic lightning pains. Long prior to these observations were those occurring in the fanatic and ecstatic of purpuric spots in areas corresponding to such points as those where the hands and feet of our Lord were nailed.

Toxic influences are many. The toxins of bacteria giving rise to degenerative changes have already been mentioned; but we must remember, too, the probability of changes in the tissues adjacent to the blood-vessels.

Searlet fever, cerebro-spinal (spotted) fever, and other infective diseases sometimes have purpuric tendencies and manifestations. Organic matter, as bile and urinary constituents; certain drugs, notably iodine preparations; snake venom and other poisons, have all been credited with causing purpura. Injection of sodium chloride into a vessel or the subcutaneous tissue of a frog, as done by Prussak, was followed by an observable diapedesis of colored corpuscles seen under the microscope to be passing through the intact wall of the vessels. This observation was confirmed by Wiekham Legg.

That changes in the constituents of the blood have a part in the causation of the purpuric diseases can not be doubted. Scurvy furnishes an example. The lack
of some constituent, and this thought to be a fibrin-forming element, is believed to be a frequent cause.

The evidence is good that there exists a specific purpuric disease, since epidemics have been reported as well as instances of contagion. Thus Taylor, in the Twentieth Century Practice, cites a case of a pig afflicted with "Irish purpura." The servant of the owner of the pig soon thereafter contracted the disease and was ill three weeks. The owner, too, contracted it, and the cowman died of it.

To recapitulate briefly, we may have purpura of any type from causes—
1. Mechanical, including nervous, from vasomotor derangements causing changes in blood pressure, etc.
2. Toxic in general, as drugs, toxins, and organic matter.
3. Purpuric disease, specific and communicable.

Of the different forms all are familiar. The following cases we believe would doubtless come under the head of purpura rheumatica:

CASE I.—James A., aged six months, had fever for two or three days prior to our observations, April 17, 1899. Had laryngitis two weeks ago. Has not been vaccinated (small-pox scare). The paperil rash present comes and goes; is most marked during fever. Temperature now 103.2° F. Examination discloses in addition to papules, petechiae suggestive of a probable hemorrhagic exanthem.

April 18, 1899.—Mother reports persistence of petechiae, some turning black. Called and found child free from fever, having a marked systolic murmur over mitral area, and the changes apparent quickly suggested purpura.

19th.—Temperature, 102° F.; rash now decidedly purpuric.

24th.—Dr. Zahorsky notes the following: "Miliaria on neck, chest, and arms; very small millet-seed vesicles, with slight areola. Sweats a great deal. Left knee swollen and painful, but not as much as yesterday; loud systolic murmur. Baby apparently quite well."

May 1st (writer’s notes).—Left knee swollen, with marked flexion of left leg. Purpuric color changes evident. Miliaria (probably drug-born) disappearing.

16th.—Been free from swelling since May 3d, but again began this morning.

This child completely recovered, but systolic murmur remained. This, so far as we know, may have been congenital.

Salicylates were tried and quinine, but found of no value. Antipyrine in grain doses four times daily reduced the fever and calmed the child. Ithethyl and bandaging for knee. No plasmoidia were found in the blood, and the character of the sweats did not suggest rheumatism pure and simple.

CASE II.—Mrs. McL., aged fifty-five years. On April 26, 1899, a wardrobe top fell, striking her on her head, shocking her greatly, but apparently not injuring her otherwise.

From this time until some time early in May she complained of weakness under her shoulder blades. At this time she found spots about the ankles and feet. She had "chilly sensations and mild fever" about four to seven in the afternoon of each day; loss of appetite and vertigo. Tonic pill. Next visit, June 11th, she reported large wheals appearing about her joints, soon followed by swelling of the joints with much pain. Feet and ankles now edematous. Chemical examination of urine negative. Subsequent history: The joint swellings would fairly quickly recede upon immersing them in hot water. The eruption covered all the extremities, and was very severe, consisting of petechiae, virebices, and ecchymoses. When lying down, her back would present thousands of petechiae.

About the ankles the skin broke, and we had several ulcers to contend with. Complete rest would in a few days cause a marked diminution of the hemorrhages except on the back and buttocks, but on assuming the erect position she would at once be covered (her lower extremities particularly) with myriads of petechiae. Upon rising after bandaging the legs and thighs she suffered from dyspnea and cardiac uneasiness, but the bandaging restrained the hemorrhages over the bandaged areas. Salicylates, ergot, dilute sulphuric acid, and diuretics when indicated, gave no results whatever except improvement in appetite and feelings due to tonics, as quinine, strychnine, and iron.

It was then, after more than two months, that we determined to try a calcium salt on certain theoretical principles (not then knowing that calcium chloride had been recommended), and concluded to resort to the glycerinophosphate because of its reputed as a nerve tonic, indicated in this case, since it was thought the shock mentioned had played an important part. Within a week after giving four grains of Merek’s salt three times daily our patient was up, and August 11th (about another week thereafter) reported at the writer’s office without a spot to tell the tale.

The blood was twice examined by Dr. Carl Fisch, who reported absence of platelets both times. On June 20th, after strangury (when ergot was stopped), he examined the urine and reported as follows: Specific gravity, 1.014; acid; granular and epithelial casts; small amount of albumin; some kidney epithelium and a considerable number of leucocytes. It is to be regretted that the patient did not bring her urine as requested when last seen, but from all evidence these changes were temporary.

Since writing the above, the patient reported August 18th, having a return of the affection starting from the effects of a severe storm a few nights previously, which gave her another shock. Having put herself in the hands of a physician (?) who promised her a permanent cure in fifteen days (I judge by "electric-belt" treatment). I now await her promised return. cured.

THE PRIMARY LESION OF TUBERCULOSIS: HOW LOCATED.

By W. H. Weaver, M. D.,

CHICAGO.

Professor of Otolaryngology, and Laryngology in the Chicago Eye and Ear, Nose and Throat College.

The usual location of the primary lesion of consumption in some portion of the lungs has influenced our ideas of the etiology of the disease in leading to the inference that it was produced by the inhalation of infectious dust. Dr. David Bovard, in the New York Medical Journal for July 1, 1899, shows that "the primary
lesion of tuberculosis in children under five years of age is regularly in the bronchial lymph nodes or lungs." This fact is demonstrated by autopsies on seventy-five cases in the New York Foundling Hospital, "sixty cases of infection by the respiratory tract and fifteen indeterminate." He also quotes Dr. W. P. Northrup on Tuberculosis in Children: Primary Infection in the Bronchial Lymph Nodes (New York Medical Journal, February 21, 1891), in which are recorded eighty-eight cases of "infection by the respiratory tract," "three cases of infection by the mesenteric lymph nodes," and thirty-four cases of indeterminate infection. Dr. Bouvard makes the inference that the mesenteric glands are infected by the swallowing of tuberculous expectoration, certain to occur in children. In order to accept this view of the etiology of tuberculosis one must absolutely reject the infectious power of tuberculous milk and other food; yet it would seem that nothing in scientific research had been more firmly established in the last several years.

Dr. W. L. West, of Ellsworth, Maine, reported that two children of a man named Luther Bridges died of tuberculosis due to drinking milk from a cow which was found, when killed, to be the subject of extensive tuberculous disease, localized in the udder. Five of Bridges's children were also suffering from pulmonary tuberculosis.

In the report of the Royal Commission on Tuberculosis in the American Journal of the Medical Sciences, September, 1895, experiments are reported in which pigs, guinea-pigs, and rabbits were fed on uncooked milk from tuberculous animals, and the disease was thus caused in a very large percentage of the subjects used.

Again, in their report of 1898, stress is laid on the necessity of a pure milk supply.

In Denmark the results of the government's experiment have been most encouraging toward eradicating the disease from the herds. Somewhat modified regulations similar to those established in Denmark are carried out in Pennsylvania, and as a result Philadelphia has a greatly reduced mortality from consumption.

Professor W. M. Late Coplin, of Vanderbilt University, Nashville, Tennessee, and Dr. Palmer, of Massachusetts, report equally conclusive results concerning the infectiousness of milk. Kirkpatrick, on The Spread of Tuberculosis by the Milk Supply, in the Dublin Journal of Medical Sciences, May, 1897, says that in his experiments it was proved that 0.05 to 0.1 cubic centimetre of tuberculous sputum diluted with non-infected milk was sufficient to produce tuberculosis.

The experiments of Zürn, Gerlach, and Klebs demonstrate the infectiousness of milk, and that the disease commenced in the form of an intestinal catarrh and infection of the mesenteric glands before the development of miliary tuberculosis.

Many other experimenters and authorities have arrived at the same conclusion regarding the infectious power of tuberculous milk.

Professor Flügge, in the Deutsche medicinische Wochenschrift, October 14, 1897, asserts that the assumption of the transmission of tuberculosis by inhalation of fine dust from dried sputa has never been proved, not even by Cornet, who originated the idea. It has been refuted by all experimental research, and there are no authentic cases on record in man.

Moist germs, however, retain their virulence and are disseminated abroad in speaking, coughing, and sneezing, floating in the tiny drops of moisture expelled from the mouth, and which may float entirely across the room.

Recently, however, Flügge reports the results of further experiments made, which show that infection by dried sputum ground to a fine dust is undoubtedly possible, but it is rare because the formation of such fine dust particles is not produced by the actual conditions of modern life. Expectoration in suitable vessels, so that drying is prevented, is an entirely sanitary procedure.

Birch-Hirschfeld, in the Deutsche Archiv für klinische Medicin, 1899, in his investigations has found that the area of lung tissue supplied by the bronchial branch designated as the ramus apicalis posterior is the usual location of the primary lesion in the lungs of adults. This area and the bronchus supplying it are from the nature of the chest wall somewhat cramped and undeveloped from puberty, being subject to very feeble respiratory movements. The dead air spaces in this area of the lung soon become unhealthy, easily congested, and favorable to the localization of the infection. Birch-Hirschfeld concludes that asepsis of the inspired air and lung gymnastics are important factors in the prevention and treatment of consumption.

It is difficult, however, to understand how the dust infection is so unfailing in its effort to get into the "dead air spaces."

In man intestinal infection is rare, considering the immense number of cases of pulmonary tuberculosis. That the lesion occurs primarily in the lungs has led to the error of considering consumption a dust-borne disease, while anatomically and physiologically the lesion should be there. Milk, butter, cheese, and possibly meat and any other infected food, are emulsified during pancreatic digestion in the intestines, and the nutritious elements, the finely divided particles, carry the bacilli directly through the lacteals without local infection. This chyle-containing bacilli, together with the lymph from the whole lymphatic system, is poured through the thoracic duct into the left innominate vein, thence with the venous blood through the right heart directly to the lungs, where infection takes place.

When the germ enters the system through the skin, it is through an abrasion, and a tuberculous ulcer forms. If it enters through the mucous membrane of the nose, mouth, or throat, the same ulceration appears. Post-
mortem examinations do not show that these ulcerations occur in the trachea, or even bronchial tubes, except in the tuberculous area. It is safe to assert that germs are not absorbed through healthy mucous membrane. It is also known that dried germs are not necessarily virulent. If moist germs are inhaled, they find lodgment in the nose, mouth, or throat, and are swallowed with the saliva and mucus of the throat, thus passing through the lacteals with the chyle to the blood of the vena cava. The reprehensible propensity of slightly catarrhal patients to swallow the mucus collecting in the throat is universal and well known by medical men.

That fine particles of dust are carried into the alveoli is proved by the disease known as pneumoconiosis, but it is doubtful if moist particles could be carried far beyond the larynx, and, if they did, infection would not take place in any case so long as the mucous membrane was intact.

Tonsillar tissue, however, does not seem to have the protecting power exerted by the skin and mucous membrane, but is easily infected. On this account Dr. J. R. Winslow, in the Maryland Medical Journal, May 13, 1899, recommends the entire removal of the tonsils by Pynchon's electro-cautery dissection, thus replacing them with scar tissue.

Others have shown that a certain percentage of pharyngeal adenoids are tuberculous, and certainly belong in the same category with the side tonsils as one of the gateways of infection next in importance to lactic absorption.

It may be stated then:

1. That the infection comes through food or moist germs inhaled and swallowed, and possibly through infection of tonsillar tissue.

2. In the great majority of cases the infection occurs in the posterior portion of the lung apex, that being the most vulnerable point, as a direct result of the discharge of infected chyle into the vena cava.

3. Should that portion of the lung apex be healthy, and not a suitable nidus for the germs, they may pass on with the current of blood to find lodgment in some other area, unless the blood has exerted its bactericidal power over them, when they may be removed by the action of the phagocytes (Klebs).

The theory of Cornet has not produced the results expected in the prophylaxis of tuberculosis. Then why consider such a rare possibility when we know that there is a stream of bacilli constantly flowing into the blood current through the lacteals, capable of producing the infection in the lungs?

92 State Street.

Changes of Address.—Dr. Winifred Davey Banks, to No. 198 Washington Avenue, Newark, N. J.; Dr. L. W. Hotchkiss, to No. 24 East Fifty-fourth Street, New York; Dr. George W. Johnston, to No. 1134 Fiftieth Street N. W., Washington, D. C.; Dr. D. Ernest Walker, to No. 254 West Forty-fifth Street, New York.

Therapeutical Notes.

Bromoform in the Treatment of Whooping-cough.—The Progrès médical for August 5th attributes the following formula to Berlioz:

R Bromoform, Tincture of aconite, Tincture of drosera, equal parts. Alcohol, Glycerin,

M. To be given in daily amounts of from ten to twenty drops, according to the child's age.

Salipyrine in Gynecological Practice.—At the recent Amsterdam Gynecological Congress, Beuttner, of Geneva (Centralblatt für Gynäkologie, September 16th), reported his experience with this remedy. He regarded it as indicated in menorrhagia, with or without disease of the annexa; in metrorrhagia, with or without disease of the annexa, provided there was no cancerous process or a large tumor; in climacteric hemorrhages; in post-partum hemorrhage and that of abortion; in threatened abortion; in dysmennorrhœa; in uterine disturbances manifested by periodical neuralgia; in all menstrual disorders not dependent on severe organic disease; and in conditions of mental depression preceding and accompanying menstruation.

A Lotion for Urticaria.—The following formula is given in the Journal des praticiens for July 29th:

R Chloral hydrate 3 parts; Cherry-laurel water 100 " Distilled water 200 " M.

Sodium Salicylate in Croupous Pneumonia.—Liegl (Wiener medicinische Wochenschrift, 1898, No. 19; Centralblatt für innere Medicin, August 12, 1899) employs large doses of sodium salicylate at the beginning of the attack, according to the following formula:

R Sodium salicylate 120 grains; Peppermint water 750 " Water 3,000 " Bitter tincture 75 " M. The whole to be given in the course of twenty-four hours.

Iechthol in the Treatment of Sciatica.—Croq (Journal de neurologie; Presse médicale belge, July 30th) gives daily from six to eight capsules, each containing a grain and a half of ichthyol, and orders the following liniment:

R Ichthol 5 parts; Glycerin 2 " Water 3 " M. To be applied with friction five or six times a day.

An Application for Exudative Coryza.—Province médicale for August 12th ascribes the following formula to Moreau:

R Iodine 1½ grain; Potassium iodide 3½ grains; Carboic acid 7½ " Laurdaniun 15 " Glycerin 675 " M. To be applied to the nasal passages with a camel's-hair brush.

NEW YORK, SATURDAY, OCTOBER 7, 1899.

THE PLAGUE AND PREVENTIVE INOCULATION.

The Proceedings of the Royal Society, vol. lxv, No. 418, for August 31st, presents, after final revision by the author, the remarkable report On Preventive Inoculation by Mr. W. M. Haffkine, D.Sc., C.I.E., who is the officer employed by the government of India on bacteriological research duty. The fact that the report was communicated to the society by no less a person than its president, Lord Lister, is full of premonitory significance. After referring to the disappointment which had followed on too hasty generalizations from the results of Jenner and Pasteur, the author says:

"When we cultivate a pathogenic micro-organism in a liquid medium two different elements are obtained mixed together: the bodies of the microbe and the liquid which it has modified, and into which it has secreted its own products. A modification of the entire preparation, as represented by this mixture, can be first of all obtained by filtering and separating the two elements just mentioned, and considering each of them by itself. Or else the two can be left together, and only the vitality of the microbe is destroyed by some physical or chemical agent. Or the constitution and properties of each or of both of these elements can be, to a desired degree, altered by the admixture of chemicals, or by subjecting them to physical processes. Or the vital and pathogenic properties of the microbe can be modified by artificial breeding, and then the microbe itself, or the products of such a modified microbe, used for treatment."

The author next deals with differences of susceptibility of different animals to different poisons, and the way in which this susceptibility may be altered by various treatment of the microbes and their toxines, and concludes by saying that in general he believes it to be admissible that in the case of every disease, and with regard to every species of animals, a form of prophylactic treatment may be found which will produce immunity against disease in that particular case; but that same method of treatment may or may not be applicable to another animal or to another disease affecting the same animal.

It is the failure of taking into account this variation of circumstances that, he believes, more than anything else has checked the success of a number of experimenters.

The study of anticholera inoculation in India has revealed a new problem in the subject of prophylactic treatment. Observations upon eight thousand people, extending over two years, in cholera-infested districts—uninoculated and inoculated people often living in the same huts—showed cases of cholera occurred in seventy-seven huts, with the result that for a period of seven hundred and thirty-eight days cases of cholera occurred among the uninoculated almost from day to day, while among the inoculated cases occurred for the first four days only, after which for a period of four hundred and sixteen days the inoculated remained practically free from the disease. Then from the four hundred and twenty-first day up to the end of the observation, the seven hundred and thirty-eighth day, six more cases only occurred among the inoculated. The proportion of deaths to cases was not, however, materially influenced, upon which the author remarks that "this circumstance, the non-reduction of the case mortality by a treatment which influenced unmistakably the case incidence, appears as an astonishing divergence from the result of small-pox vaccination, where both the number of attacks and their fatality are reduced by the treatment."

"The new aspect of the problem of preventive inoculation which thus presented itself in these observations on human communities consisted in the possibility of a prophylactic treatment being directed separately toward the reduction of the number of attacks, leaving the fatality of the disease unchecked, and toward the mitigating of the character of the disease and the reduction of the case mortality in those who get attacked."

On being confronted in 1896 with the plague problem, the author, bearing in mind the discoveries of Behring and Kitasato on immunization by gradually increasing doses of toxines, and that of Gamaleia regarding immunity to lethal doses of virulent microbes apart from immunity to their toxines, determined to aim at inducing two separate kinds of immunity: one against the living microbe, which would prevent it from entering the system and causing an attack, and another against the fatality of the symptoms of the disease caused by the products of the microbe when the latter overcomes the initial resistance and does invade the system. In other words, he resolved to obtain, by treating the system with a combination of the microbial bod-
ies and their toxines, a new preventive inoculation which should obtain at the same time a lowered susceptibility to the disease and a reduction of the case mortality.

The author next describes his procedure, and continues:

"At the end of our laboratory experiments a set of questions stood before us that were to be solved by direct experiment on human beings. Those questions were:

"1. Would man behave with regard to the prophylactic like the animals upon which its protective power had been worked out?

"2. If it so happens that the answer is affirmative, what would be the dose of the prophylactic and the method of administering it be; and would not the dose required be so high, and the reaction to be produced so severe, or the number of inoculations to be repeated so great, as to render the treatment inapplicable to men, or impracticable?

"3. How many days, counting from the date of inoculation, would it take to produce in man a useful degree of immunity?

"4. How long would that immunity last?

"And, lastly, there followed two questions, to which my experience of the anticholera inoculation entitled me to give a reassuring answer, but the correctness of which it was necessary to demonstrate afresh in the case of plague, viz.:

"5. During the period of reactionary fever and all the other symptoms produced by inoculation, will the resistance of the inoculated exposed to plague be, for the time being, reduced, or remain the same, or be increased?—i.e., would it constitute a danger to apply the inoculation in localities actually affected with plague? and

"6. When a man who happens to be incubating the plague, or to have initial symptoms of the disease already, chances to be inoculated, would it aggravate his condition, or have no effect, or, on the contrary, help him?"

The harmlessness was made clear by the inoculation of the officers of the laboratory, the principal and professors of Grant Medical College, and many European and native gentlemen of Bombay.

The use of the prophylactic was next subjected to three extensive tests. In Byculla Jail on the appearance of plague the comparison of 147 prisoners inoculated as against 172 uninoculated gave the following results: Uninoculated, 172, with 12 cases and 6 deaths; inoculated, 147, with 2 cases and no deaths.

From these experiments Mr. Haffkine deduces the following answers to five of his six questions—viz.: 1.

Man does behave as laboratory animals do in relation to the prophylactic. 2. The dose was found to be a single injection of three cubic centimetres, reduced in later operations to two and a half, and the reaction was shown not to be too severe. 3. The difference in favor of the inoculated began to be manifest in twelve hours. 5. The inoculation did not make the subjects more susceptible, but, as results showed, less so. 6. As regards those incubating plague at the time of inoculation, the prophylactic apparently had no effect. Question 4, as to the length of time for which immunity was conferred, could not yet be answered.

The next experiment was made on the occurrence of plague in the Umerkadi Jail in Bombay. Here 127 were uninoculated and 147 inoculated, with the following results: Uninoculated, 127, with 10 cases and 6 deaths; inoculated, 147, with 3 cases and no deaths.

The author observes that in the three cases occurring among the inoculated the character of the disease was so mitigated that the director-general of the Indian Medical Service diagnosticated them as mumps. They were, however, returned as cases of plague, so that no possibility of error in favor of inoculation should be admitted.

When plague broke out in Dharwar Jail, five cases, of which one was imported and four occurred among old prisoners of that jail, resulted fatally in every instance. The entire body of prisoners, numbering 373, then voluntarily submitted to inoculation and only one case followed, and that in a man attacked two days after the inoculation. He recovered.

A further experiment was made among the free population of Undhera, in which, prior to the inoculation, 79 victims had succumbed. The plague continued for forty-two days after inoculation, appearing in twenty-eight families. The results were as follows: Uninoculated, 64, with 27 cases and 26 deaths; inoculated, 71, with 8 cases and 3 deaths. Showing 89.65 per cent. of deaths fewer in the inoculated than in the uninoculated families.

It is needless to go in detail through the other experiments at Lanowie, Kirkee, Damaon, Hubli, Dharwar, and Gadag, the results in all cases fully sustaining previous records. In the three last places named 80,000 people were inoculated. The difference in mortality from plague in the inoculated and uninoculated averaged between eighty and ninety per cent., the lowest results attained being at Kirkee, where it was 77.9 per cent.

Mr. Haffkine concluded by outlining the following points for elucidation by continued research:
The perfecting processes for turning out large and uniform quantities of material, and avoiding the variations due to the character of the plague microbe, and to the differences in the composition of the cultivation media.

The further investigation of the different constituents of the plague prophylactic, with a view of intensifying those which produce definite and beneficial results:

The possible mitigation of the reactionary symptoms after inoculation and

The study of the effect of antiseptics used for preserving the prophylactic.

No better comment on Mr. Haffkine’s work can in our opinion be made than that uttered by the president of the Royal Society, Lord Lister, who said that the address must have convinced any one who before the meeting might have had doubts as to the value of preventive inoculation; and as to meeting all requirements for further progress he was convinced that no better person could be found to pursue the problem than Mr. Haffkine himself.

INTESTINAL IRRIGATION IN DISEASE OF THE VERMIFORM APPENDIX.

While it is now almost universally conceded that the treatment of inflammation of the vermiform appendix should be essentially operative, there is perhaps too great a tendency to look upon other measures as useless, the idea that such measures may pave the way to the successful use of the knife or supplement its results being lost sight of. With this consideration in mind, we have been much interested in a paper entitled The Non-operative Treatment of Appendicitis, by Dr. T. J. Shuell, of Parnell, Iowa, for a copy of which, reprinted from the Transactions of the Iowa State Medical Society, we are indebted to the author.

Dr. Shuell grants that in the great surgical centres the operative treatment of appendicular disease has vastly reduced the mortality, but he maintains that there has not been the same reduction of the death-rate in general practice, and this he imputes largely to the general practitioner’s natural disposition to rely on medicinal treatment so long as that seems to hold out the least prospect of relief, with the resource in reserve of calling in a surgeon when medication is shown to be powerless, for it has been taught, he says, that the knife may be used at any period of the disease with a fair prospect of success, and this teaching has induced surgeons of small experience to operate at the height of the inflammatory process, often with disastrous results.

Dr. Shuell distrusts alike opiates and purgatives—the one because they mask symptoms and restrict peristalsis, and the other because they lead to a pumping of the contents of the small intestine into the already overloaded colon. But there is a measure which he thinks well calculated to tide a patient over the period during which an operation could not be done to the best advantage, and, indeed, to wholly obviate its necessity in many cases. This is frequent and copious irrigation of the colon. He believes that it not only tends to preserve patency of the orifice of the appendix, but also often actually dislodges concretions if they are not lodged at a point too remote from the cecum. We should not advise too much reliance on this last-named possibility, but we have no doubt that flushing of the colon may be of material service in many cases. Dr. Shuell says that he has employed it in twenty cases during the last four years, and that in every case but one there was amelioration of the symptoms within forty-eight hours. In the exceptional case, which he did not see early, convalescence from the attack was tedious, there were two or three relapses, and the patient was finally cured by means of an operation performed during an interval of freedom from acute symptoms. Surely this is a showing which may be called very satisfactory.

MARK TWAIN ON CHRISTIAN SCIENCE.

Much as has been written in refutation of the absurdities of Mrs. Eddy’s puerile cult, it is probable that the trenchant satire of our old friend Mark Twain on Christian Science and the Book of Mrs. Eddy, in the October number of the Cosmopolitan, will, by reaching a wider circle, effect more than all other efforts put together. That it will convince any person who has been already able to swallow the contradictions and the tissue of self-refuting statements contained in Science and Health, with a Key to the Scriptures, is not to be hoped for. Nothing short of a miracle could effect that. But it will probably exert a strong effect in the region of prevention, which, as we all know, is “better than cure.” For humor the inimitable writing of Mark Twain can not be paralleled, but in the serious part of his argument also he traverses, with the same trenchant force we find in his humorous remarks, the very root of the whole matter. When the world generally realizes the enormous part played in all the functions of life by mental operations in stimulating or inhibiting nervous action, controlling the local blood supply, increasing or diminishing secretion and excretion, and retarding or accelerating metabolism, etc., it will see that it is pos-
sible that in many cases the touch of the king's hand may have seemingly cured "king's evil," that "saints' relics" may have effected a cure in cases of more than mere hysterical conditions, and that faith healers, mind curers, and Christian Scientists may sometimes effect veritable curative results; but it will realize at the same time that it is neither the virtue of royalty, nor the sanctity of relics, nor the occult power of quasi-religio-scientific systems that is the operative force in effecting the results, but, as Mark Twain says, "the same old powerful instrument—the patient's imagination. Differing names, but no difference in the process." It will further realize at the same time that it is only in those conditions which are controlled by the purely subjective, in which the factors of disturbed vital action are integral parts of the human economy and not intruders from without, and, moreover, in which the disturbed action has not been so long persistent as to produce extensive organic change, that the force from within is sufficient to overcome unaided the interference with function, or to effect its partial restitution when the mechanism itself has undergone actual metamorphosis. The cases that have been cured under Christian Science are, without a single proved exception, such as could have been equally cured by any modus operandi, whether at the hands of quacks or physicians, that would have inspired sufficient confidence in the patient to render him amenable to the influence of suggestion. Mrs. Eddy knows that—and that is why the Christian Scientists have ignored Dr. C. A. L. Reed's challenge published in the New York Sun of January 1st, a challenge which gave them a fair opportunity to substantiate in a convincing manner their claims to effect more than has been herein conceded to them.

THE MECHANICAL TREATMENT OF PTOSIS.

It seems strange that, notwithstanding all the surgical measures that have been devised for the relief of ptosis, mechanical means have apparently been entirely lost sight of in the text-books. Dr. Edward B. Heckel (Pennsylvania Medical Journal, September) describes in an illustrated article a device so simple in its nature that it is a wonder that it should have remained so long unthought of. The author found that Goldzieher (Centralblatt fur Augenheilkunde, 1890) had reported a horn spectacle with a horn rim in the upper plate which, when the spectacle was adjusted on the nose, pushed up and kept up the drooping eyelid, thus acting as a sort of crutch. Dr. Heckel has modified Goldzieher's idea by the attachment of a piece of gold wire to the upper rim of an ordinary spectacle frame, bent in a fashion somewhat resembling the curved flange on Noyes's improved eye speculum, but situated, of course, when in position, externally to the eyelid instead of between it and the ball. The proper adjustment must be made by the surgeon, so as to insure accuracy and comfort. It is asserted that this appliance, by reason of its elasticity, does not irritate the eye, and permits of both winking it and closing it. The author has used this device successfully in four cases.

AN OVERZEALOUS HUMANE SOCIETY OFFICIAL.

Our New York Society for the Prevention of Cruelty to Children is generally credited with quite a sufficiency of zeal, but, if the newspaper accounts are true, it seems to have been outdone lately by a representative of the New Haven Humane Society who threatened a New York man with arrest because his little daughter appeared on the street wearing hose instead of stockings. The story is that the New Yorker having been given an hour in which to provide the little girl with stockings, preferred to take his family back to New York.

THE DEWEY RECEPTION.

Pleasure is not the only thing that may result from pageantry; some weakening generally goes to the wall in consequence of the attendant fatigue, exposure, etc., even when no catastrophe happens. Fortunately, the enormous aggregations of people who assembled to witness the naval and land parades last week felt but a minimum of the untoward effects that are apt to be incident to such displays. No doubt this was largely owing to the favorable weather, but, so far as accidents were concerned, much credit must be given to the city officials, who took unusual pains to insure stability in the stands.

MUNICIPAL PARADISES.

The British Medical Journal for September 23d, in an editorial on Street Noises, complains of the sufferings of Londoners on that score, and incidentally mentions that in Eastbourne "only two barrel organ grinders are allowed in the place, and they on sufferance; while the milkmen do not make a sound." Again, "in Croydon, Bath, Brighton, and the counties of Kent and Surrey no crying of goods or street music is permitted on Sunday." London is not the only city that has occasion to look with envious eye on these minor British municipalities. New York is especially a city of din and turmoil. Its noises are as distracting as they are unceasing. Noise is a nervous irritant of the worst kind, and the formation of a Society for the Suppression of Street Nuisances, such as that which has already accomplished considerable work in its first year of life in London, would have scope for an honorable career in New York.

THE PRINCIPLES OF TREATMENT.

In the Maryland Medical Journal for September 23d Dr. Walter B. Platt complains of the meagre instructions on treatment given in most text-books. He says: "I have yet to see a medical work devoted to treatment which was written in what I believe to be the proper way—viz., to give exact directions (as far as possible) for treatment during the different phases of a given disease, citing half a dozen or more clinical cases, to show the probable effect of treatment upon certain painful, inconvenient, or dangerous symptoms." There is some logic in this position. A handbook of treat-
A MISHAP WITH THE BINAURAL STETHOSCOPE.

Since the publication of Holmes's account of the curious revelations of a young doctor's new stethoscope we remember nothing of the sort more ludicrous than a story recently published in the Chicago Journal. It is to the effect that a physician was about to examine an applicant for life insurance, a member of the brass band who prided himself on his lung power. Thinking that some demonstration of this power was expected of him, he took the barrel of the stethoscope in his mouth and blew a mighty blast home upon the doctor's ear drums. The doctor, the story went on to say, was still suffering with tinnitus aurium and wearing cotton in his ears.

ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending September 30, 1899:

Marine-Hospital Service Health Reports.—The following cases of small-pox, yellow fever, cholera, and plague were reported to the surgeon-general during the week ending September 30, 1899:

- **Small-pox—United States.**
  - Everett, Mass. Sept. 15-23... 1 case.
  - Memphis, Tenn. Sept. 15-23... 1 "
  - Portsmouth, Va. Sept. 15-23... 1 "

- **Small-pox—Foreign.**
  - Antwerp, Belgium Sept. 2-9... 1 case.
  - Prague, Bohemia Aug. 26-Sept. 9... 6 cases.
  - Rio de Janeiro, Brazil July 27-Aug. 11... 121 " 63 deaths.
  - Cairo, Egypt Aug. 19-26... 1 case.
  - Bombay, India Aug. 5-29... 12 cases.
  - Athens, Greece Sept. 2-29... 7 "
  - Chihuahua, Mexico Aug. 19-26... 3 "
  - Moscow, Russia Sept. 2-10... 3 "
  - Odessa, Russia Aug. 26-Sept. 9... 1 death.
  - Warsaw, Russia Aug. 26-Sept. 9... 8 deaths.

- **Yellow Fever—United States.**
  - Key West, Fla. Sept. 25-29... 166 cases, 9 deaths.
  - Miami, Fla. Sept. 5-22... 2 " 1 death.
  - New Orleans, La. Sept. 15-23... 16 " 4 deaths.

The Buffalo Academy of Medicine.—At the last regular meeting of the Section in Surgery, on Tuesday evening, the 3d inst., the following papers were presented for discussion: A Report of the Operative Treatment of Several Cases of Frontal and Maxillary Sinusitis, by Dr. Frank W. Hinkel; and Subphrenic Abscesses, by Dr. Prescott Le Breton.

Marine-Hospital Service.—Official List of Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the United States Marine-Hospital Service for the Seven Days ending September 28, 1899:

- MEAD, F. W., Surgeon. Granted leave of absence for two days.
- BLYE, RUPERT, Passed Assistant Surgeon. Granted leave of absence for one month and eight days from October 6th.
- TABE, S. R., Assistant Surgeon. To proceed immediately to South Atlantic Quarantine for temporary duty.
- VON EDDORF, R. H., Assistant Surgeon. To proceed to Miami, Florida, for special temporary duty.
- BILLINGS, W. C., Assistant Surgeon. Relieved from duty at New York, and directed to report in person at the bureau for temporary duty in charge of the Miscellaneous Division.
- BAILEY, C. W., Acting Assistant Surgeon. Granted five days' leave of absence.
- WALKLEY, W. S., Acting Assistant Surgeon. Granted leave of absence for four days.
- COMFORT, N. C., Hospital Steward. To report at the bureau for orders. To proceed immediately to New York and report to Passed Assistant Surgeon H. D. GEDDINGS for assignment to duty in charge of the steamer Wapiti on her voyage from New York to Florida.

Births, Marriages, and Deaths.

Married.

THE LAW IN ITS RELATIONS TO PHYSICIANS.*

By ARTHUR N. TAYLOR, LL.B.

XXXIX.

CRIMINAL LIABILITY.

(Continued from page 496.)

Guilt to be Determined by Jury.—In determining whether or not, in a given case, a physician has been guilty of such gross professional conduct as to render him criminally liable, the question is one of fact which it is the defendant’s constitutional right to have submitted to a jury for determination.† The jury, in arriving at their conclusion, are not to be governed by the usual test applicable in civil matters, and find the accused guilty because a preponderance of the evidence submitted shows guilt, but they must, before convicting, find the evidence showing guilt to be so strong as to exclude all reasonable doubt of innocence. Such a doubt must, however, be one founded upon the circumstances and evidence, and not a doubt resting upon mere conjecture or speculation.‡ This is the test applicable in all criminal matters.

Intoxication of Physician.—The fact that the fatal treatment may have been superinduced by drunkenness, or that the physician may have been in an intoxicated condition while rendering the services that resulted in the patient’s death, would at common law be a circumstance for the jury to take into consideration in determining whether the defendant had been guilty of grossly improper conduct. The legislatures of several States have, however, expressly provided that a physician who administers while intoxicated a poisonous drug or medicine which results in death shall be held guilty of manslaughter, and many of the States have passed laws making it a misdemeanor for one to practise as a physician while intoxicated.*

No Right to Terminate Life.—The question of whether or not the physician ever has the right to terminate life, either that of a patient hopelessly ill and suffering intense agony, or that of a newly born monstrosity, has been very interestingly discussed, rather from an ethical than from a legal standpoint, before the Medico-Legal Society.† Legally speaking, no such right exists.

Obtaining Money under False Pretense.—Similar to the civil liability resulting from deceit is the criminal liability from obtaining money under false pretense. An interesting case of this sort was recently passed upon by the court of appeals of Maryland. Here the complaining witness called upon the defendant for medical treatment. The details of the interview are perhaps best told in the words of the witness, which were as follows: "The professor offered me paper and told me to write my name and age upon it, and not let him see what I wrote. I wrote my name and age upon the paper, and he walked up and down the room and looked out of the window, and took the paper and folded it up, and placed it against his forehead, and then told me what I had written on the paper. He said, ‘You suffer from stomach trouble, and I can and will cure you within six weeks; if not, I will return you your money.’ I asked him when I should call again, and he said, ‘Don’t come; I will come and see you and work on you four hours, and after that you will be well.’ He also gave me a charm to wear. I wore it around my neck for one hour. He said to wear it was essential to the treatment. I am not over the stomach trouble yet. He never came to my house and worked on me. I paid him twenty-six dollars and thirty cents." After this, and before the time fixed for curing the witness, the defendant left.

It will be remembered that no expression of opinion or promise of future events will ordinarily afford ground for an action based upon deceit. Upon similar grounds it is held that the criminal action for obtaining money under false pretense cannot be based upon a promise of future profits or benefits. The counsel for the accused in the present ease, therefore, contended that the accused’s promise of future benefit would not sustain such a prosecution. The court was, however, of the opinion that the essential part of the transaction was the accused’s representation that, in effect, he was then and there possessed of supernatural power whereby he could cure witness. This part of the transaction was no promise as to the future, but a positive assertion of a present condition, and the fact that a promise of future benefits operated with this representation as a part of the inducement under which the witness parted with his money would not operate to defeat the prosecution. The prisoner was held guilty.‡

The purpose of this chapter being to examine only those questions of criminal liability resulting from the

* The following erata occur in Mr. Taylor’s thirty-seventh article, published in our issue for September 23d: The reference on the second column should read, “Becker vs. Janinski, 27 Abb. N. C., 45”—not 48. In line 42 of the third column read, “at what points the report does not show.” The conclusion of the article should read, “a complete bar to another action brought for the recovery of such future damages.”

‡ U. S. vs. Knowles, 4 Sawy., 621.

Such acts have been passed in the States of California, Idaho, Michigan, Minnesota, Montana, Nebraska, New Mexico, New York, North Dakota, Ohio, Oregon, South Dakota, Utah, Washington, Wisconsin, and Wyoming.

† An interesting paper on the subject, by Clark Bell, Esq., may be found in vol. 1r, Albany Law Journal, p. 136.

improper exercise of professional duties and the exercise of professional functions which are in themselves unlawful, notice will not be taken of those cases in which the physician has been guilty of criminal conduct of an ordinary character, even though committed in the course of his professional relations with his patients.

Criminal Abortions.—The most prolific source of criminal litigation growing out of the conduct of the physician in the exercise of the functions of his profession is the procurement of abortions.

Abortion as a criminal act seems to be of comparatively recent origin, as neither the ancient law writers nor the early English statutes refer to it as such. In many of the States the procurement of an abortion with the consent of the mother, before the child became quick, was not at common law considered a criminal act. The theory upon which the courts arrived at this conclusion was that the procurement of an abortion when the mother had given her consent to the operation, could be considered a wrong as against the child only. According to Blackstone, life begins, in contemplation of law, as soon as the infant is able to stir in the mother's womb; therefore, prior to this period the law did not, at least for the purposes of the present inquiry, recognize the child as in esse and capable of being the object of a criminal intent or act. The early statutes in several of our States apparently recognized this distinction in providing that the killing of an unborn "quick" child should constitute the crime of manslaughter, etc.

This distinction is, however, forcibly repudiated by the Pennsylvania courts in the case of Mills vs. Commonwealth, wherein the court, in reference to the contention that the absence of an allegation that the mother was quick, rendered the indictment defective, said: "Although it has been so held in Massachusetts and in some other States, it is not, I apprehend, the law in Pennsylvania, and never ought to have been the law anywhere. It is not the murder of a living child which constitutes the offense, but the destruction of gestation by wicked means and against Nature. The moment the womb is instinct with embryo life and gestation has begun, the crime may be perpetrated." This case was followed as a precedent by the supreme court of North Carolina.

Notwithstanding the fact that it was at common law not generally considered criminal to commit an abortion upon a woman, with her consent, before the child quickened, yet if one performed such an act and the death of the mother ensued he was held guilty of murder. This was upon the ground that the act was without lawful purpose and dangerous to life, and that the consent of the mother could not take away the imputation of malice or criminal intent.

It seems that at common law an abortion, when committed with the mother's consent, and after quickening, was not a crime, but only a misdemeanor, which could not be punished by imprisonment in the State prison.

This question is now regulated by statutes in the several States which specify what acts shall be considered tantamount to the crime in consideration and provide penalties for their violation. These statutes in most States now fail to draw any distinction between the commission of the offense or attempt at commission before and after the quickening of the child, making it a felony in either case. The statutes of some States, however, preserve the distinction by providing a more severe punishment when the act or attempt is committed after quickening.

A detailed examination of the statutes of the several States would require a greater space than can here be devoted to that purpose; we will therefore pass over the subject with a general statement of the most usual provisions contained in such statutes, which are that any person who shall administer to any pregnant woman any medicine, drug, or noxious thing, or who shall use or employ any instrument or other means with intent to produce a miscarriage, unless the same shall be necessary to preserve her life, shall be guilty of a felony.

Some States provide that the performing or attempting to perform an abortion shall be a misdemeanor, and that in case death results from the act the party performing the same shall be guilty of manslaughter. The effect of such statutes is, however, simply to reduce the crime of performing or attempting to perform an abortion from that of a felony to a misdemeanor, for the provision that the party performing the operation shall be guilty of manslaughter when death ensues does not in any material respect alter the common law. The common law upon this subject seems to be that where one attempts to cause an abortion in a way not to inflict serious injury upon the mother, and the mother dies from negligence in the operation, there being no intent to kill her, or to inflict serious injury, and no likelihood of such result, the offense is manslaughter; if, however, the act is one from which death or great injury would be likely to result, or if it were performed with intent to produce death or grievous injury, then the offense is murder.

The liability of the mother for causing herself to miscarry, it seems at common law was regarded much the same as that of a third person. If she committed the abortion before the child had quickened she was not guilty of a crime, but if after quickening she was considered guilty. The statutes of the several States making it a crime for any person to administer to any pregnant woman any drug, etc., for the purpose of unlawfully producing an abortion, are construed as applying to third parties who commit such acts, but not as incriminating the mother who performs an abortion upon herself. Nor was the submission of the mother at common law to the act of another in producing an abortion upon her held to render her an accomplice in the commission of the crime. She

was looked upon rather as a victim of the act than
as a particeps criminis.*

Statutes have, however, been enacted in some States
making it a criminal offense for the mother to take
any medicine or use or submit to the use of any in-
strument for the purpose of procuring her own mis-
}carriage. Such a statute, it will be seen, entirely super-
sedes and alters the common law.†

Advice to Produce an Abortion.—The mere solici-
tation or advice given to a pregnant woman that she
take medicine or adopt means to produce a miscar-
riage does not constitute a crime unless the solicita-
tion or advice is acted upon. In the case of Lamb vs.
State,‡ the act upon which the prosecution was based
was the solicitation of a pregnant woman to take cer-
tain drugs for the purpose of causing an abortion, but
it was not shown that the woman did take the drugs.
In this case, after observing that the act complained
of was not included in the terms of the statute, the
court said: "It may be urged that a solicitation is
an attempt, and that an attempt to commit a mis-
demeanor is a misdemeanor. Pursuing the same train
of inference and reasoning, we may go a step farther,
and maintain that as the solicitation is a misdemeanor,
an attempt at solicitation would, by the same rule, be
also a misdemeanor. This process might be indefinitely
extended, so as to reach persons very remotely separated
from the act which the statute intended to punish.
Certainly it would be a great calamity to invent crimes by
subtle, ingenious, and astute deduction. In all free
countries the criminal law ought to be plain, perspicu-
ous, and easily apprehended by the common intelligence
of the community. It is the essence of cruelty and
injustice to punish men for acts which can be con-
strued to be crimes only by the application of artificial
principles according to a mode of disquisition unknown
in the ordinary business and pursuits of life."

A more recent and a stronger case than the above
was decided by the New York court of appeals in 1892.*
Here the crime was charged as having been committed by
advising a pregnant woman to take a medicine,
drug, or substance, and to use means to procure a mis-
carriage; but it was not shown that the advice was
acted upon. The statute under which the defendant
was prosecuted provided that "a person who, with
intent thereby to procure the miscarriage of a woman,
un]less the same is necessary to preserve the life of
the woman, . . . advises or causes a woman to take
any medicine, drug, or substance, . . . is guilty of
abortion, and is punishable, etc." The court said: "It
would be a very strict and literal, if not extraordinary,
construction of this section to hold that proof of mere
suggestion or advice, without evidence of its being acted
upon, could convict a man." The court, in discussing the
question further, after observing that it would
be competent for the legislature to impose a penalty
for mere giving advice to a woman to take a medicine
to produce an abortion, irrespective of its being acted
upon, said: "For the man to be ‘guilty of abortion’
within the provisions of this chapter, who has advised
the woman to take a drug, it is necessarily and logi-
cally to be implied that his advice should have been
followed by the act. Otherwise we should have to draw
the apparently absurd conclusion that the legislature
intended that abortion could be committed or caused
by the act of offering advice."

Intent, Rather Than Efficiency of Means Employed,
Govern.—In one of the first English statutes* enacted
for the purpose of preventing the procurement of
abortions, the expression "any poison, drug, or
noxious thing" was made use of in describing an un-
lawful means of performing the forbidden act. This
expression has been reenacted in the statutes of many
of our States, and is judicially defined as being any
drug, medicine, or other thing which is hurtful or
harmful.

Under the New Jersey statute which makes it a
crime to administer any drug, poison, medicine, or
noxious thing with intent to produce an abortion, the
court held that it was not necessary that the drug
or medicine used should accomplish the effect designed,
or should even be capable of producing a miscarriage;
but if it is hurtful and is administered, prescribed, or
advised with the intent to cause a miscarriage, the
crime is complete the moment the medicine is taken.
The reasoning of the court in this case is based upon
sound policy, and should commend itself as correct
law whenever the question may in the future arise.
Justice Scudder, in assigning the reason for this
conclusion, said: "The design of the statute was not so
much to prevent the procuring of abortions, however
offensive these may be to morals and decency, as to
guard the health and life of the female against the
consequences of such attempts . . . It is dangerous to
the life and health of the mother and to the existence
of the child to experiment with any drug, medicine,
or noxious thing to produce a miscarriage. The igno-
rance of the operator may lead him to select some-
thing that will not have the effect he designs; but if
it be noxious in any degree, though in the judgment
of others who have greater knowledge it can not pro-
duce the effect intended, it is within the statute."

In a case † similar to the one above, and in which the
law was held substantially as there stated, the su-
preme court of Colorado held that the character and
capabilities of any drug alleged to have been used in
the procurement or attempted procurement of an abor-
tion are questions of fact to be determined by the jury
upon the evidence before them. In referring to the es-
sential element of the crime the court said: "The acts
sought to be prohibited and the crime sought to be pun-
ished are the using of noxious substances and instru-
ments with intent to produce miscarriage. It is not ne-
cessary that the miscarriage should take place—that is,
that the administering of the drugs or the use of the in-
strument should be followed by the expulsion of the
foetus. That is not necessary to constitute the crime. It
is the administering the noxious substance or the use
of the instruments with intent to produce miscarriage
that makes up the crime."

A recent case in apparent conflict with the doc-
tine upon which the preceding cases are based comes
from the Texas court of appeals." A more careful

† State vs. Geddie, 43 N. J. Law, 86.
‡ Dougherty vs. the People, 1 Colo., 514.
§ Williams vs. State, Tex. App., 19 S. M. Rep., 897.
examination of the case, however, shows that the conflict is only apparent, for the decision is based upon the wording of the Texas statute which requires that the means employed to produce the abortion shall be calculated to be efficacious. Here the accused administered cotton-root tea. Experts for the State testified that while medical books said an abortion was liable to follow the administration of cotton-root tea, they knew nothing of it by personal observation, and thought that as administered to the prosecuting witness by the defendant it was not calculated to produce an abortion.

Upon the question in consideration the case of Commonwealth vs. W.* is instructive. The statute under which the defendant was prosecuted was as follows: "If any person, with intent to procure the miscarriage of any woman, shall unlawfully administer to her any poison, drug, or substance whatsoever, or shall unlawfully use any instrument, or other means whatsoever, with like intent, such person shall be guilty of felony." The evidence in this case tended to show that the defendant had been guilty of improper liberties with the complaining witness; that shortly thereafter her fears were excited by an irregularity in her monthly courses, and that she made this known to the defendant. He expressed the belief that she had taken cold, and advised the use of a tea, and afterward brought her a phial of iron tincture, instructing her to take ten or fifteen drops before meals for the purpose of strengthening her. Professional evidence was given that the iron could do her no harm, but on the contrary was a benefit to her.

The court instructed the jury, in effect, that the motive or intent of the defendant in furnishing the prosecutrix with the iron should govern in determining his liability; that at the time the iron was given there was no certainty of pregnancy, and that his motive as expressed did not indicate a criminal intent; yet if they concluded from all the circumstances that the drug was administered with intent to procure a miscarriage, they should find the defendant guilty. The evidence further showed that the prosecutrix, after undergoing violent and excessive exercise, jumped from a ladder, the effect of which was to cause a miscarriage. Whether or not this means, if induced by the defendant, rendered him liable under the statute was a question strongly opposed by the defense, who urged that the words of the statute defining the crime, "or shall use any instrument or other means whatsoever," imply some act to be done by the defendant and not by the woman herself under his advice. Upon this question of law the court said to the jury: "We have given this question some reflection, and our conclusion is, to submit the case to you upon the evidence, with the instruction that the third count (alleging the excessive exercise and jump as an act induced by the defendant) sets forth the offense within the intent and meaning of the act of assembly."

"We are not prepared to adopt the view of the law presented by the defendant's counsel, for the reason that such an interpretation would greatly abridge what we conceive to be the remedial design of the act, and to a great extent frustrate the expressed intention of its framers. If a person intent on inducing an abortion must not only prescribe the drug, but with his own hand put it to the victim's lips, or, after contriving the mechanical means, must to moral constraint superadd physical force, we can readily perceive how the abortionist may practise his nefarious schemes with impunity in the very face of the statute. Upon the commonwealth's evidence, the case is one of criminal abortion—that is, unlawful means were made use of to procure a miscarriage. The defendant, according to the evidence, contrived these means, and used the prosecutrix in rendering them efficacious; what she did was as much his act as if she had been moved to it by outward constraint. The means used to produce the abortion, therefore, were used by the defendant just as much as if he had employed physical instead of moral force."

Upon the question of fact to be determined by the jury the court instructed them that they were to consider carefully all the evidence, and from that determine whether the defendant conceived the violent and excessive exercise as a means of producing a miscarriage, and whether he induced her to employ it with intent on his part of producing a miscarriage.

The jury failed to agree and were discharged. The prosecutrix soon removed to another State, and it seems was prevented from returning and appearing in court by declining health. A nullus prosequi was therefore entered and the defendant dismissed.

(To be continued.)

Pith of Current Literature.

The Treatment of Ulcerative Stomatitis.—Kissel (Progrès médical, September 2d) rinses the child's mouth every hour with a three-per-cent. boric-acid solution and rubs twice daily the entire buccal cavity, and particularly the gums and ulcerated parts of the mucous lining of the cheeks, with a plug of cotton wet with the same lotion. Cod-liver oil is prescribed, and before commencing treatment unsound teeth (dents tout à fait inutiles) are extracted. Under this treatment ulcerations are said to disappear in from six to ten days. In private practice, when such minute attention is not possible, the author, after extracting the teeth as before, curettés the ulcerations to the bottom, then with a finger enveloped in gauze he rubs iodiform powder into the ulcerated surfaces. The buccal cavity is cleansed twice daily with a tampon of cotton wet with the same boric-acid solution and the mouth is rinsed hourly with the same solution.

The "Moth Ball" as a Protection against Mosquitoes.—One of the little white balls known as "moth balls," which appear to contain a crude form of carbolic acid or some equally fragrant coal-tar product, rubbed on a mosquito bite, has considerable efficacy in allaying the itching. Moreover, when rubbed upon the face and hands, it seems to keep the mosquitoes away.

The Contagiousness of Leprosy.—Dr. J. Ross Mahon (Lancet, September 16th), after describing a case of leprosy contracted in England by a man who had never been out of Britain, remarks that a man who had never been beyond the confines of England, who belonged to a healthy stock, and who had no ascertainable intercommunication with any source of infection should become a leper leaves no alternative but to

* Com. vs. W., 3 Pittsb. R., 463.
assume that he happened to meet with some source of infection within those shores. Bearing on this point, he would state that though he can not boast of being in a favorable position for meeting with cases of any particular disease—to say naught of leprosy—he knows personally of some eight or nine lepers in London.

How, he asks, did this man become infected with leprosy? As an illustration of the facilities which exist for infection, he mentions the case of a Russian married woman, thirty-two years of age, who was a leper, and afflicted with the most virulent type of the disease which it was possible to conceive. From head to foot she was one ulcerating mass, with large anaesthetic areas; she had the typical leonine face, and she was bereft of several fingers and of all but two of her toes. From the ulcers a copious sanguineous discharge was exuding, and her case was rendered the more loathsome by the abominable smell which emanated from her body. She had married an Irishman in Russia nearly thirteen years previously and had been in this terrible condition for the last few years, sometimes better and sometimes worse. She never infected her husband, although he cohabitated with her until three years ago. The author was particularly careful to elucidate this point. He saw the woman in London about two years ago. She had crossed from her residence in Ireland to secure hospital treatment. On arriving in London she obtained a lodging in a small third-rate hotel. There she spent one night, and he believes left to return to Ireland. It is notorious that in such hotels the bed sheets have in many cases to do service on more than one occasion, and it is obvious, therefore, how in one way infection may be possible in London. The author thinks it is a pretty generally accepted theory, although he is aware of one prominent authority who dissents from this view, that leprosy is conveyed by intimate contact with the source of the infection, and it is extremely interesting to find that the male or female leper can cohabit with a wife or a husband for years without imparting infection. The author knows of at least three male lepers and one female leper who are married and have been cohabiting with healthy partners for years without imparting infection to them. In connection with this he has noticed the translation of a paper by Azuero in which he remarks upon the fact that women do not shrink from cohabitation with lepers and that he has never known a case in which they were infected by coitus with them; but numerous authenticated cases demonstrate that other healthy males indulging in coitus with leprous women become infected. Azuero has observed forty cases and Carrasquella over one hundred cases in which the husband or the wife remained unaffected by the other’s disease throughout a long married life. When the author saw the man to whose case he had referred he at once thought of the woman from Ireland staying at the third-rate hotel and the vision of the sheets crossed his fancy.

The Relative Toxicity of Cocaine and Eucaine.—Dr. H. H. Peck (Journal of the American Medical Association, September 9th) says that his experiments lead him to the following conclusions:

1. The action of cocaine is inconstant; one never knows whether the symptoms occasioned by like quantities of the drug, in animals or individuals, under like circumstances, will be similar or dissimilar.

2. The action of eucaine is constant. The symptoms occasioned by the use of like quantities in animals under like circumstances, and, so far as the author’s experiments have gone, in different individuals also, are the same.

3. The first action of cocaine on the heart is that of a depressant, and on the respiration it is that of a mild stimulant, the after-effects being, on the heart, that of a decided stimulant, and on the respiration, that of a decided depressant.

4. The first action of eucaine on both the heart and respiration is that of a stimulant, the after-effects being those of a decided depressant.

5. Cocaine causes death in animals by paralyzing the muscles of the respiratory apparatus, the heart’s action continuing in a feeble way for a brief period after breathing ceases.

6. Eucaine causes death in animals by paralyzing the muscles of the heart and of the respiratory apparatus, which cease to operate simultaneously.

7. Eucaine in toxic doses nearly always causes nausea, and occasionally vomiting.

8. Cocaine is much less nauseating and scarcely ever causes vomiting.

9. Eucaine is decidedly a diuretic, causing renal discharge in a majority of instances in which a toxic dose is used.

10. Cocaine is not a diuretic to any appreciable extent, renal discharge having occurred in only one instance in connection with all the author’s experiments.

11. The pupils of the eyes, in nearly all cases of cocaine poisoning, do not respond to light, and the eyes are more or less bulging from their sockets.

12. The pupils of the eyes, in most cases of eucaine poisoning, do respond feebly to light, and the eyes rarely bulge from their sockets.

13. The action of toxic doses of eucaine is more like that of a paralyzing, tetanoid, convulsion-producing agent than of an anæsthetizing one, the plantar and cremasteric reflexes nearly always responding.

14. Toxic doses of cocaine cause general anaesthesia in connection with the other symptoms in the majority of cases.

15. True tetanus of all striped muscles of the limbs, and Cheyne-Stokes breathing, nearly always occur with the use of cocaine, but seldom does either occur when eucaine is used.

16. Cocaine is at least three times more toxic than beta eucaine, and alpha eucaine is as toxic as cocaine.

17. Boiling does not destroy the efficacy of cocaine, but it does modify it, and boiling in no degree lessens the efficacy of eucaine.

The above deductions have been made only after many experiments in connection with each individual point. The author has observed many interesting features in connection with the relative worth of these drugs as local anaesthetics, but his paper does not treat of this phase of the work. There is much experimental work yet to be done in this connection, the results of which he will present at some future meeting.

Hereditary Syphilis.—Mr. Jonathan Hutchinson, F. R. S., F. R. C. S. (British Medical Journal, September 16th), speaking recently at the Brussels Conference of Social Hygiene, said that in his opinion hereditary syphilis would disappear if the rule was generally adopted that two years’ interval after infection should elapse before marriage. He held, in opposition to Professor Fournier, that syphilis was not dangerous to the race, but disappeared in the third generation. Under
the modern use of mercury syphilis was curable and was generally cured.

Dangerous Flowers.—M. Domingo Freire (Journal de médicine de Paris, September 31), as a result of researches instituted by him on flowers, shows that flowers can afford a resting place to saprophytic and pathogenic microbes and thus become a source of contamination. He thinks, moreover, that some relation exists between the colors of flowers and the pigment elaborated by the microbes which find shelter in them. The rosy tint of the Rothschild rose is similar to that of a plate culture of Leptothrix ochracea before it arrives at the brick-red stage. The egg-yolk yellow of colonies of Micrococcus cruciformis he finds to be of the same tint as that of the coloring matter on the anthers of the Hibiscus rosa sinensis. Furthermore, many kinds of microbes that the author would term “osmogenous” reproduce odors resembling those disengaged by the essences of the plants in which they live.

Poisoning from Artichokes.—According to the Sanitarium for September, M. Roger has reported to the Société de biologie a small epidemic of gastro-enteritis which occurred in his practice recently, which he was able to trace directly to the ingestion by those attacked of preserved or canned artichokes. Examining the contents of one of the boxes, the vegetable was found to be of a handsome, almost natural, green color, which at first gave him the idea that he had to deal with the effects of a copper salt. Chemical analysis, however, revealed no trace of that metal. He then submitted the material to an examination by bacteriological methods, and was able to isolate a colon bacillus and a micrococcus. The latter, on pure cultivation, was found to have the property, when cultivated on slices of artichoke, of communicating to the latter an intense green color. The micrococcus is pathogenic to the rabbit.

The Early Diagnosis of General Paralysis of the Insane.—Under this title Schwarz (St. Petersburg medicinische Wochenschrift, 1899, No. 4; Albany Medical Annuals, September) discusses pupillary anomalies with especial reference to their relations to the incipient stages of general paralysis. General paralysis usually presents a row of symptoms which permit an easy diagnosis, but in its incipency, when the chance for amelioration is afforded, they are so ambiguous as not to be of service in the diagnosis. This is especially true of the mental manifestations. Certain bodily symptoms, however, may give warning, and chief among these are the changes in the pupils, especially the variations in their reaction to light. The writer examined fifty early cases of paralysis, and found that in four there were no pupillary reactions; in sixteen there was isolated double-sided immobility to light—that is, neither pupil reacted to light, although both responded to convergence and accommodation; in seventeen cases the reaction was more or less sluggish, so slow that it could only be seen with a magnifying lens, or it was withheld in one eye and present in the other; and in thirteen cases the pupils were normal. The author then reviews the literature of this subject, including observations upon a much larger number of patients. The reflex palsy may be one-sided, but is generally double. Gowers has noted in a case of locomotor ataxy a qualitative reaction, in which the pupil responded promptly to light, but immediately dilated, and to a greater degree than before the contraction; there may be cited as a curiosity the so-called paradoxical reaction, in which the pupil dilates instead of contracts upon the exposure to light. Hippus has also been once observed, but, as this condition is generally physiological, or, when pathological, may stand for neurasthenia, acute meningitis, hemiplegia, multiple sclerosis, and other conditions, its significance must not be misinterpreted.

Reflex pupillary immobility has been found also in locomotor ataxy, senile dementia, alcoholism, focal cerebral lesions, cerebral syphilis, traumatism of the head, epilepsy, hysteria, and paranoia. The relations of this symptom with locomotor ataxy complicated by mental symptoms is especially interesting. In one such case seen by the writer, the patient was profoundly melancholy; his history showed that in youth, before the acquisition of syphilis, he had suffered from melancholy, and his case record thus shows that the combination of symptoms does not justify the anticipation of general paralysis. As in all the cases the greatest number by far were those of general paralysis; the author is justified in attaching great importance to the pupillary manifestations. He summarizes as follows: 1. In the great majority of cases of insanity in which reflex immobility of the pupil is present (ninety-two per cent.) the diagnosis of general paralysis is justified. 2. In the great majority of cases of general paralysis (seventy per cent.) isolated reflex immobility of the pupils is found. 3. Isolated double-sided pupillary immobility is characteristic of general paralysis. Still in the earliest stages a limitation of the pupillary reaction may have a similar significance as above—(1). 4. Immobility of the pupils combined with failure of the convergence reaction does not negative the diagnosis of general paralysis. 5. Isolated double-sided pupillary immobility may exist for years without the development of general paralysis or locomotor ataxy. 6. It is an early symptom of general paralysis, and has been seen for years before the ensuing general paralysis has developed.

Sleep, Sleeplessness, and Hypnotics.—Dr. Bradbury (British Medical Journal, July 15th; University Medical Magazine, September) states, in the Croomian Lectures, that the great principle of therapeutics—the removal of the cause—should ever be kept in mind. The causes of insomnia may be classed under four heads: irritative, toxic, psychical, and those arising from change in the mode of life.

1. Irritative Causes.—This class includes all forms of insomnia caused by pain and milder irritations—teeth, indigestion, worms, eye strain, inconvenience of faecal adenoids, cold feet, asthuma, and vesical irritation.

2. Toxic Causes.—Under this head may be mentioned alcoholism, gout, nicotism, gastric and intestinal disorders, Bright’s disease, and excessive use of beverages.

3. Psychical Causes.—Grief, shock, worry, and mental anxiety are among the most frequent causes of insomnia.

4. Causes arising from the Change in the Mode of Life.—Eating late dinners by those unaccustomed to them and change of climate sometimes give rise to insomnia.

After removing the cause, hypnotics are often of great value in breaking the habit of sleeplessness. The best of these for any individual will vary according to his condition. There is no absolutely safe one, but experimental investigation and clinical experience show
that paraldehyde stands in the first rank. Chloralamide and chloralose are safer, but slower in action, than chloral hydrate, and of the two the author prefers chloralamide. The sulphones (sulphon, trional, and tetranitrate) are also valuable, and in practice he has found sulphon the most valuable of the three. On the whole, the bromides seem to be the least harmful, and in simple cases, uncomplicated by other disease, it is his practice to try them before resorting to any other drug.

Sleeplessness from overwork, and especially literary work, requires mental rest and change of air and scene. Temporary exposure to the cool air of the bedroom, or the wet pack, or a bath is often useful, and so is a glass of whisky and water at bedtime, especially in those unaccustomed to the use of alcohol. Twenty grains of sulphonal, or thirty or forty grains of potassium bromide, may be given to break up the habit of sleeplessness. Capsules containing thirty minims of turpentine, given at bedtime, are sometimes beneficial in the insomnia of overwork and worry. The drug acts as a stimulant and derivative, and is stated to act best in plerotic cases. No beverage containing caffeine should be taken after breakfast. In nervous and hysterical women, and especially in women at the menopause, the bromides are very useful. The writer has long been in the habit of giving a mixture of bromide, tincture of sumbol, and tincture of hops, in camphor water at bedtime; and it has helped to remove the insomnia as well as the mental depression, flushing, and heats so common at this period. In pneumonia sleep comes usually at the crisis; but where this has not occurred, he has occasionally seen a hypnotic, such as chloralamide or paraldehyde, turn the scale in favor of the patient. In pleurisy live to ten grains of Dover's powder usually induce sleep, mainly by relieving the pain. A hypodermic injection of morphine may be given with the same object in view. In bronchitis chloral and chloralamide are safe hypnotics, and, as a rule, opiates are to be avoided, as they depress the respiratory centre. The insomnia of heart disease is benefited by cardiac tonics; but in some cases it is necessary to resort to morphine, either by the mouth or better, hypodermically. Paraldehyde and chloralhydrate are most useful in the writer's experience. Ice to the head is recommended by Morison, where the vital forces are not too low or the temperature subnormal. It often produces sleep rapidly, with a more regular cardiac action. In chronic Bright's disease insomnia is occasionally very troublesome. Eliminants, such as aperients, should be tried, and if they do not succeed chloral hydrate may be given; the drug is safer in kidney disease than in heart disease, the reduction of blood pressure being usually more beneficial than otherwise.

Morphine and hyoscine subcutaneously injected have been recommended in obstinate cases; but their employment requires great caution. Ethyl alcohol tetrani, by reducing arterial tension, often acts as a charm even when sedatives fail. In cases of neuralgia, locomotor ataxia, and so forth, some of the synthetic analgetics—phenacetine—are of value. These drugs act also as hypnotics in cases where there is no pain. Calcium chloride is a valuable remedy in the insomnia due to pruritis. But when pain is the causal factor of insomnia, morphine is the best general remedy, and this should be pushed until relief is afforded.

Arecoline.—Cleneh (Buffalo Medical Journal, September) says that araceline is one of the alkaloids found in the areca nut, the seeds of the Areca catechu. Taken internally, it causes vomiting and diarrhoea and will be found useful in obstinate constipation from its action on the contractility of the intestine. According to Frohner, arecoline is a salutary of the first rank, and is not only comparable to pilocarpine, but even exceeds it in value. Salivation occurs in about five minutes after its injection and attains its maximum in half an hour. Martin employed this drug as a tanning liquid, using sixty grains of the powdered areca nut to obtain the desired effect, and he specially noted the absence of colic. The bromohydrazide of arecoline is a white, crystalline, soluble salt, which when applied to the eye in the form of a one-half or one-per-cent. aqueous solution causes contraction of the pupil. A one-half-per-cent. solution dropped into the conjunctival sac causes burning and slight conjunctival congestion. In from three to five minutes the pupil begins to contract and reaches its maximum in from ten to fifteen minutes, accompanied by spasm of the ciliary muscle. The maximum effect remains for a quarter of an hour or so, after which the pupil gradually returns to its normal condition, usually in the course of an hour or two. The tension of the normal eye does not seem to be affected by it, but in cases of glaucoma clinical results show this drug to be the equal of eserine. Bietti observed that it appeared to act more promptly and more energetically than eserine, but that its effect was of shorter duration. It keeps well in solution, retaining its active properties unchanged for an unlimited period.

Rules for the Practice of Intubation without Constant Subsequent Supervision.—Dr. M. E. Escate (Archives internationales de laryngologie, de rhinologie et d'otologie, xii, No. 2, 1899; St. Paul Medical Journal, September) lays down the following rules under which intubation may be practised without constant subsequent supervision. 1.

1. Intubation may be practised among one's clientèle when the patient lives within such a distance that the physician could be called and reach him within two hours, in case of accident.

2. The superiority of intubation over tracheotomy in cases of croup is such that, if we were called into the country to see a case of croup, in the period of asphyxia, we would not attempt tracheotomy unless the resisting powers of the patient were such as to guarantee a successful operation. On the other hand, if syncope were imminent, we should perform a provisional intubation; and when the child had rallied somewhat, and been placed in a better condition to continue the fight, the question of a tracheotomy might be discussed. 3.

Intubation may be performed whenever the dyspnoea becomes threatening. If called to a case toward night where the dyspnoea is only moderate, we may intubate and thus avoid a sudden and pressing call later on. 4.

In the case of a tube one should act with reference to the apparent rather than the real age of the child. Try to use the tube next larger than the one indicated by the gauge. The tube should glide and not fall into the larynx; if it slips in too easily, take the next larger size. It is an advantage to perceive the cricoid resistance as the tube passes in, for this assures us that it will be held firmly in place. If by reason of edema we are obliged to use too small a tube, this should be changed for a larger size at the end of twenty-four hours; or one might leave the thread attached. 5.

Before introduction, the tube should be coated inside and out with mentholated oil. 6. The patient should be kept in an atmosphere charged with moisture, either with a spray or steam apparatus.
supplied with some antiseptic solution. 7. When the cough becomes dry and expectoration difficult, threatening an obstruction of the tube, an intralaryngeal injection of several drops of mentholated oil may be made, or, better still, the tube may be changed. 8. One should not leave the patient until satisfied that the tube is well placed. This may be accomplished by causing him to swallow a few drops of liquid from a teaspoon. This at first invariably brings on an attack of coughing. 9. The patient should be visited twice a day. One of the visits should be made as late as possible. 10. The patient should be considered as in a grave condition and the family warned of possible accidents. 11. In case of sudden suffocation from obstruction, a pharyngeal injection may be made. This will bring on an attack of coughing which may bring up the tube, provided that the downward flow has not removed the obstruction. If this does not succeed, the patient should be tipped over the side of the bed with the head hanging very low. This position favors the expulsion of the tube. 12. Exstirpation should always be done in the morning, as one may find it necessary to reintroduce the tube some hours later. 13. After extirpation the physician should remain at least half an hour. A sudden and threatening dyspnœa (spasm or paralysis), such as would render a reintroduction necessary, will always appear very shortly after the tube is removed; whereas a slowly increasing dyspnœa (oedema of the uraeus or the existence of false membranes) would give ample time for the physician to be called to the house. 14. The physician should always be ready to come to the case at once, and should keep the family informed, as far as possible, just where he can be found at any given time.

A Distinct Variety of Hip-joint Disease in Children and Young Persons.—Edmund Owen (Medico-chirurgical Transactions, vol. lxxxii; St. Paul Medical Journal, September) says that after acknowledging the frequency of tuberculous disease of the hip joint, traumatic synovitis or arthritis, and admitting the rarity of syphilitic and ostitis-arthritis inflammation, there still remains a very important group of hip-joint diseases which should be recognized and distinguished from the foregoing diseases, with which they have not infrequently been confused, viz., septic disease of the upper end of the diaphysis of the femur, spreading into the synovial cavity and rapidly involving the hip joint in an acute and devastating suppuration. In children there is no disease more sudden in its onset or disastrous than acute arthritis of the hip originating from septic myelitis. The peculiar anatomy of the parts makes the joint especially prone to be attacked by the micro-organisms of septic myelitis, as well as by the bacilli of tuberculous. The invasion of the germ follows injury to the limb or any condition which lowers the vitality of the tissue and thereby renders it less capable of resisting the invasion of the staphylococci; thus scarlet fever, measles, typhoid fever, or influenza may forerun the attack of acute suppuration of the hip.

In many cases in which the surgeon opens the hip joint and finds the solid head of the femur detached from the neck and scarcely affected by various disintegration, the cause of the separation has been septic inflammation just below the junction cartilage. The sound detached epiphysis and its even contour are proofs that the separation occurred early in the course of the disease and before the joint was occupied by granular tissue. This condition is very different from the "worm-eaten," irregular shaped appearance in tuberculous disease.

The symptoms of this acute condition of the joint differ widely from those of the tuberculous form in that the onset is sudden, in a few days the symptoms attaining alarming intensity, the child having all the appearances of sepsis, even at times delirium, temperature as high as 104° F., or showing depression instead of elevation. The low temperature is explained by assuming "that the dose of toxic material elaborated by the growth of micro-organisms may be so intense that the heat-producing centre, like every other area, is profoundly affected; this general depression may end in a fatal collapse." The local symptoms are similar to those of tuberculous disease—that is to say, pain in the hip, though more severe and intensified by motion, and night crises. The onset is decidedly different from the slowly developing symptoms of tuberculous hip-joint disease, where there is in the beginning only a slight limp, a little pain now and then, and gradual increase of stiffness, etc.

The disease might be mistaken for an acute rheumatic affection or for unusually acute symptoms of a tuberculous inflammation, but the importance of early diagnosis is apparent, for upon this depends the prognosis.

The indication for treatment in these cases can not be questioned, nor should we wait until the abscess is demonstrated by fluctuation, but it should be opened up, thoroughly washed out, disinfected with a hot solution of zinc chloride (ten grains to the ounce), and thoroughly drained. If the septic focus is entirely removed the patient is not only completely and promptly restored to comfort, but may make an immediate recovery. A detail of the operations and treatment of cases demonstrates the importance of early distinguishing this acute condition of the hip joint from tuberculous disease of that joint.

Egg Albumen in Illness. — "Sister Elizabeth" (The Hospital, August 5th; Dublin Journal of Medical Science, September) contributes an instructive article on the free use of raw white of egg in the diets of youngish women suffering from anaemia, gastric ulcer, and dyspeptic troubles of a more or less severe character. The usual proportion is two whites of eggs to one pint of cold water, but if a more concentrated form of nourishment is desired double that number may be used without inconvenience. Beat the whites of the eggs well first, then stir them thoroughly into the water, and strain the mixture through a fine sieve before administration. The mixture is tasteless, and if given alone may be flavored with vanilla, cinnamon, etc., but when given in milk and whey it is better unflavored. From personal observation of the administration of egg water to patients suffering from dyspepsia, gastritis, and gastric ulcer, Sister E. has learned that the results have been a quicker cessation of pain and uneasiness after food, and a steadier march toward convalescence than in those cases where it was not given. After a course of nutrient enemata a teaspoonful or two of albuminous water—i.e., egg water—every hour is a safe and nutritious way of beginning mouth feeding again. In three cases where the patients were having large enemata of ten ounces of peptonized milk every six hours, the addition of the raw white of an egg was made with good results; there was an entire absence of diarrhoea and discomfort—a great gain, as all these cases were fed
only by enemata for ten days or a fortnight. In a fourth case the addition of white of egg made no special difference, and the enemata were only moderately retained, but it should be added that the patient was taking two teaspoonfuls of Carlshad salts every morning, so that a looseness of the bowels was to be expected. In cases of obstinate vomiting egg water is very useful, and will often be retained when nothing else is. Combined with whey, in bad cases of typhoid fever where milk is not tolerated and is speedily vomited in a curdled, undigested condition, it forms a good food for some days, till the use of milk can be resumed. Taken in its concentrated form (four whites of eggs to the pint) it proved of the greatest service to a young woman suffering from a severe attack of typhoid fever in the above-mentioned ward, all sickness stopping after its administration, and the strength being well maintained. Children with diarrhoea and vomiting have benefited by taking it alone and in conjunction with whey, when it has been advisable to stop the use of milk for a time. Stimulants may very well be diluted with albumen water instead of plain water in cases where it is desirable to increase the nutrition. Egg water should not be added to boiling, or even to very hot liquids, as the rapid coagulation of the albumen under heat will at once render it indigestible, and negative the hoped-for good results. It is well known in France as "eau albuminée," and one is inclined to surmise it to be a "good remedy out of fashion," though none the less valuable on that account.

Operations in Gastric Ulcer.—Dr. Leonard A. Bidwell (American Journal of Medical Sciences, September) recapitulates as follows the class of cases of gastric ulcer in which an operation should be done: 1. In all cases of perforation at the very earliest possible moment; also in subphrenic abscesses. 2. In cases of hemorrhage (a) when there is continual oozing of blood, especially if the stomach is dilated, and (b) in cases of repeated severe hemorrhage. 3. In cases where there are severe pain and vomiting unaffected by treatment, and which are producing progressive emaciation. 4. In cases of dilatation of the stomach from contraction within or from adhesions outside the stomach. The operations to be performed are: In class 1, laparotomy and suture of the ulcer; in class 2, gastrostomy and suture of the ulcer with a purse-string suture, combined with gastro-enterostomy; in class 3, gastro-enterostomy, in order to give physiological rest to the ulcer; and in class 4, either gastro-enterostomy or, if the pylorus is affected, pyloroplasty or pylorectomy. As the surgery of gastric ulcer is a comparatively new subject, the author has had, so to speak, to make a case in its favor. It has been his endeavor to show that no patient ought to be allowed to die either from perforation or from hemorrhage from a gastric ulcer without a surgical effort being made to save him; that the earlier such effort is made the better the chance of success, and, finally, that surgery offers much hope of success in other cases which resist the art of the physician.

Callosities due to Certain Occupations.—Dr. H. S. Purdon (Dublin Journal of Medical Science, September) says that persons employed in certain trades bear on various parts of their bodies the marks of their calling. You can tell a sweep or a flour miller by looking at him when in working clothes; but the cases to which he refers are due, in the first instance, to an excess in the nutrition of the skin, causing excessive growth, followed by a "hard, thickened condition of the skin, due to pressure and constant friction,—in other words, to a callus or callosity. It is possible, he says, in many instances to tell the occupation of a person from the nature and situation of his callosities. Moreover, from a medico-legal point of view, the identification of a person might thus be satisfactorily settled. These trade "marks" are due to want of moisture in the cuticle, caused by the pressure of the tools or other mechanical appliances used by the worker at his occupation.

A French physician, Dr. Vernois (De la main des ouvriers et des artisans, au point de vue de l'hygiène et de la médecine légale), has written on callosities produced in different arts and occupations.

The trades which Dr. Purdon has noticed callosities to be caused by are, first, on the right hand—in huck- dries, on the entire internal surface of hand; burn- nishers, on fingers and internal surface of hand; flax hecklers, on index finger of right hand; shoemakers, on fingers of right hand and palm of hand; wood carvers, on radial border of index finger; cabinet- makers, on internal surface of fingers of hand; composi tors, on index finger and thumb; carpenters and joiners, on internal surface of hand and fingers; the left hand—locksmiths, on thumb and index finger and thenar eminence; sailors, on palms of both hands; on the fore arms—washerwomen, who wash in tubs, on the cubital surface of both forearms; on the thighs—shoemakers on the anterior surface of left thigh; on the knees—slaters, on both knees; on the feet—tailors, over fifth metatarsal bone externally; on the sternum—wheelwrights, over epigastric region. The skin is thickened and in a callous condition in the situations named.

Many other occupations have their characteristic callosities, as the tip of the fingers of the left hand in "cello" players; three fingers of a drummer, the thighs of a harpist. Gilders of metal, lacemakers, and horsemen (ischiaid region) have special callosities.

The author remarks that when the cause is removed, as by the person ceasing or taking to another occupation, the skin takes on in time a natural condition, and the hypertrophied callous state disappears.

Book Notices.

The Treatment of Pelvic Inflammations through the Vagina. By WILLIAM R. PRYOR, M. D., Professor of Gyneæcology, New York Polyclinic; Consulting Surgeon, City (Charity) Hospital; etc. With One Hundred and Ten Illustrations. Philadelphia: W. B. Saunders, 1899. Pp. 248.

EVIDENTLY Dr. Pryor is a man of positive convictions, and in this book he teaches them with the insistence of enthusiasm. We are bound to add that in the main his tenets meet with our approval. His style of writing, while from the grammarian's point of view it leaves something to be desired, is clear, direct, and sententious, bordering at times on the epigrammatic.

"The spirit predominant throughout this book," says the author in his preface, "is that of an aggressive interference." It is largely devoted to operative pro-

A Cosmetic Objection to Abdominal Pelvic Surgery. —Dr. T. B. Eastman (Medical and Surgical Monitor for August 15th), in a paper on Conservative Pelvic Surgery, says that the advocates of the vaginal route in pelvic surgery maintain that the frequency of hernia consequent upon the suprapubic method affords an argument in favor of the former method; whereas, the fact is that the stuffing of the vaginal opening with gauze results in such a poor union of the parts as to make the protrusion of bowel quite as objectionable as a ventral hernia. According to Cordier, the French object to the disfigurement of the abdomen by a scar, as they are great admirers of a fair complexion and an unblemished skin. He naively remarks, “A suprapubic scar and a low-necked dress may be incompatible in Paris.”

The Continuity of the Germ Plasm and Reincarnation.—According to an editorial note in the Medical Age for September 10th, Swami Viva Kananda, the Hindu teacher and philosopher, who is so well known to many in America, has been using the Weismann theory of heredity in support of the Vedanta doctrine of reincarnation. He maintains that the notion of the continuity of the germ plasm has come almost to the door of the doctrine of reincarnation. Weismann, in denying the inheritance of acquired characteristics, regards variations as a result of natural selection, the influence of which has reacted upon the germ plasm. Vedanta teaches that the germ plasm is a subtle reincarnating body containing potentially all the experiences, characters, and desires possessed by the individual in a previous form of life. It is not surprising, says the Age, that a physiology which has so many elements of the transcendental in it should approach closely to the tenets of a philosophy so largely metempirical.

To Harden Plaster of Paris.—According to the Medical News for September 23d, a hardening fluid, which will be useful to surgeons for making plaster splints last longer, and also for protecting them against moisture, has been granted a patent in Germany. The liquid may be mixed with the plaster or applied subsequently to the splints. The solution is prepared by dissolving boric acid in warm water and adding thereto sufficient ammonia to form the borate, which remains in the solution. The manner of using the solution is thus described: The saturation of the gypsum or painting of the plaster of Paris is carried out in the cold. The objects are subsequently rinsed off and dried. The surface becomes very hard after two days and insoluble in water, while the induration in the interior advances more slowly.

A Canine Maternal Impression.—Mr. John Booth, house surgeon to the South Charitable Infirmary and County Hospital, Cork (British Medical Journal, September 16th), is responsible for the following: “A very interesting occurrence has lately come under my notice. A very handsome thoroughbred fox terrier bitch, belonging to a friend of mine, strayed, and was missing for a day or two, and when found it was discovered that her right fore leg was broken. The limb was set under chloroform with the help of the Röntgen rays, and the dog made a good recovery. Several weeks afterward she gave birth to a puppy whose right fore leg—that is, corresponding to the mother’s broken limb—was ill developed and was minus the paw. The literature is full of cases of maternal impressions in the human family, but this contribution from the lower creation is, so far as I am aware, unique.”

Another Version of why he had Three Lanterns.—Dr. Albert S. Ashmead gives the following version of the story published in our issue for September 9th. It is quoted from a Japanese paper called Keifu (Laugh-town): The head devil of hell once became curious to know whether there existed really a doctor who had never killed a patient. He sent an emissary to the earth to make the necessary inquiries; for he intended (a singular idea in a devil) to reward magnificently such an individual if he should be found. The emissary went his way, and found that every doctor’s gate was literally occupied and besieged by ghosts. He understood at once what that meant, as will the reader. Finally, he came to the door of a physician where only a score of phantoms were lingering. He was surprised, and entered at once to ask the doctor for an explanation of the scarcity of shades. “Why,” answered the doctor, “I have practised only since yesterday.” Here is another Japanese story about doctors, taken from the Kaikichio—that is, Stories to make you Laugh with Wide-open Mouth: A robber broke into a doctor’s house at night. The doctor awoke, the robber drew his sword. Instantly the doctor seized a spoon and fearlessly went for the invader, whereon the latter dropped his weapon and ran away as fast as he could. When he joined his accomplice, who was waiting for him, he explained what had happened. “Why,” said the other, “you had a well-sharpened sword.” “Oh, yes,” replied the first, “but the doctor had his spoon, which is a far more formidable weapon, and has killed more people.”

Death of a Canine Philanthropist.—From the London letter of the American Practitioner and News for August 1st we learn that “Leo,’ the dog belonging to the Women and Children’s Hospital, is no more, and has been succeeded in his benevolent exertions by his eldest son. Some time ago the dog won the proud distinction of carrying off the cup offered by the Prince of Wales to the dog who collected the largest amount for a hospital. He was always to be seen in the streets with his collecting box strung round his neck, and during his life he collected upward of one thousand pounds.

Epistaxis Caused by a Leech.—Dr. A. J. Manasseh (Lancet, September 16th), writing from Beyrount, says that a young child was recently brought to him suffering from nasal hemorrhage. His mother said that the bleeding, which was from one nostril, had been continuous, off and on, for three days. The blood was dark in color and soon clotted. No blood appeared through the mouth. The child looked anemic, but there was no in-
MISCELLANY.

"As Most Management entitled regular tioners,tors, The forceps ical office -540 Blood with At the American year. Hydriatic dentist special report on the being Medical to medical to Commercial dispensing on Elixir American medical to drinking law was resulted to this case of scurvy; the amount stated in the Journal vol. ii, p. 1424, sub capitare Elixir. "Elixir de Garus [Fr. Cod.], Latin, elixirium Gari. An elixir made by first macerating for two days one part of Crocus sativus and two parts of Vanilla planifolia in 2,000 of alcohol de Garus and filtering; next by infusing forty parts of Adiantum pedatum in 1,000 of boiling distilled water, straining with expres- summing, and adding 400 of orange-flower water and 2,000 of white sugar to form a syrup; then mixing this with the maceration of saffron and vanilla, and filtering." Any French pharmacist would probably make it.

Mortality Statistics in the Twelfth Census.—We have received the following from the Department of the Interior at Washington:

"Physicians and students of mortality statistics will be interested in learning of the work now being accomplished by the chief statistician of vital statistics of the United States Census, by the authority of the director, Hon. William R. Merriam. It is a practical effort, necessarily of limited scope, to secure the adoption of a uniform certificate for the return of deaths and looking toward the establishment of a common national system of collection of vital statistics for the purpose, primarily, of the census tables and publications.

"Correspondence has been had by the chief statistician, Mr. William A. King, with the officers in charge of mortality registration in the States employing such a system, and in the cities having a population of five thousand and more at the last census which also collect and register death returns. Complete and accurate information of the different methods in vogue has been obtained, and it was found that there is much unnecessary and objectionable variation, considered from the census point of view, in the form of official returns.

"Having no power to compel cooperative action, and hampered by want of time in which to carry out the whole project, nevertheless the census office undertook to secure the modification or amplification of the death certificates so as to have them include the items necessary to obtain census data. A model return form was prepared and submitted, with explanatory correspondence, to each registration office or officer controlling the preparation of the State or local forms.

"The result has been more important and gratifying than even the census office expected, as not only have the items in the specimen form been very generally adopted, but the registration officers have abolished many practically obsolete local variations in their certificates, and the latter have been made to conform to one standard more nearly than ever before.

"The promptness and willingness displayed by the State and local officials in complying with the request of the directory has been surprising as well as gratifying. The benefit that will result to the census office and to science from this first step toward the goal of national uniformity is incalculable, but it will be seen readily that the study of the natural law of the growth of the population is made easier and more certain.

"The director of the census confidently expects that physicians everywhere will appreciate the desirability of the new order of things, and that they will earnestly and actively cooperate in securing prompt and accurate mortality returns of the uniform character required by congress and sought for by statisticians. He recognizes the fact that failure on the part of physicians to give vitality to the common standard by carefully reporting the items that may be new to their certificate will be fatal to the end in view."

American Dentists Practising Abroad should be careful to investigate the laws of the country as regards titles. According to the Journal of the American Medical Association for September 23d, the sign "Dr. Sylvester, American Dentist," at the entrance to his office in a French city resulted in the condemnation of the dentist on two indictments: 1. For practising under a pseudonym, as his name was in reality Sylvester Baumgartner. 2. For neglecting to append the source of his medical diploma, the court asserting that dentistry being a branch of medicine, the derivation of the title of "Dr." must be stated on the sign to conform to the French law in respect to aliens practising in France.

The Commercial and the Professional Spirit.—Dr. G. B. Jacobi (British Medical Journal, September 16th), writing on the commercial spirit among English medical practitioners, especially with reference to practitioners dispensing their own medicines, says: "As a contrast to this commercial spirit I should like to mention the professional sensitiveness of the Swedish doctors, who do not even send in bills for their attendance. Most Swedish families send their doctor a check once a year, whether he has been in attendance or not during the year. The amount varies according to their means. The doctor does not send a receipt, but simply his card, with many thanks and wishes for a happy new year. None of the commercial transactions mentioned above are known, neither do Swedish medical men act as midwives. All have to pass the state examination, and have spent about ten years at the university. Their social position is as good as that of any other profession, the law, the army, etc."

The New York Academy of Medicine.—At the last regular meeting, on Thursday evening, October 5th, the special order was a paper by Dr. Virgil P. Gibney entitled Certain Aspects of Bone and Joint Diseases of Interest to the General Practitioner.

At the next meeting of the Section in Pediatrics, on Thursday evening, October 12th, Dr. Walter Lester Carr will present a case of scurvy; Dr. Helen Knight will report orthopedic cases; Dr. A. Jacobi will read a paper on Antipyresis in the Febrile Disorders of Infancy and Childhood—Antipyretic Drugs, their Use and Abuse in the Treatment of Fever; and Dr. Simon Baruch will read one entitled Hydriatic Measures in the Management of the Febrile Disorders of Infancy and Childhood, with Practical Demonstrations of the Various Hydriatic Procedures.

A PLEA FOR THE
MORE FREQUENT DIGITAL EXPLORATION
OF THE UTERINE CAVITY,
AND THE HISTOLOGICAL STUDY OF UTERINE SCRAPINGS
AS AN AID TO THE
DIAGNOSIS OF DISEASES OF THE UTERUS.*

By William E. Swan, M.D.,
Saratoga Springs, N. Y.
Formerly Assistant Resident Gynecologist, Johns Hopkins Hospital,
Baltimore.

Notwithstanding the fact that the diagnostic procedures suggested by the title of this paper have been for years in active, and one might almost say in routine, use in the best clinics of Europe, especially those of Germany and Austria, in this country, except in a few instances, they do not seem to have been sufficiently appreciated nor to have been at all extensively employed. Our methods of exact diagnosis in all departments of medicine are becoming each year more satisfactory and complete, and as a rule Americans are keeping abreast with the times. But while this is especially true of uterine pathology, it has, I am sure, been the unhappy experience of all of us to repeatedly observe cases of event so common a malady as cancer of the uterus, the nature of which had remained unsuspected by the medical attendant while in the operative stage, and which had been sent to the hospital only after such ravages had been made by the disease as to render all operative treatment useless. These and similar observations would seem to suggest the great importance of more extensive discussion, and of a broader appreciation of our present knowledge bearing on the subject of exact methods in gynecological diagnosis.

My main object, then, in bringing before your notice the methods in daily use in the German clinics for the digital exploration of the uterine cavity, which, so far as I have been able to discover, has been but rarely employed here at home in the case of the non-puerperal uterus, except by Banga (1), of Chicago, and also in directing your attention to some recent improvements in the technique in common use for the securing, staining, and study of the uterine mucosa, is not to instruct but rather to stimulate among the members of this society a discussion bearing on this field of pathology. I shall also cite a few cases which have come under my notice, which serve to demonstrate with what comparative simplicity and certainty the present percentage of correctly diagnosed cases may be augmented to the material credit and comfort of the profession and the saving of many lives.

* Read before the Medical Society of Saratoga Springs, N. Y., February 24, 1899, and by title at the October meeting of the New York State Medical Association, New York City.
morphine are occasionally necessary to relieve pain. The temperature is taken every four hours, and if there is any fever the tampon and tent are immediately withdrawn and an antiseptic douche is given. After twenty-four hours the patient is taken to the operating room and the tent, having been withdrawn, and the vulva and vagina having been thoroughly sterilized again, if the cervix will admit the sterilized index or middle finger of the left hand is at once introduced into the uterus, the fundus being grasped firmly by the right hand. If the cervix will not yet admit the examining finger, it is further dilated by the cautious use of Hegar’s dilators, beginning with one easily admitted and increasing by successive sizes, each being left in position until the "bite" on it by the cervical ring has relaxed. Immediately after the withdrawal of the last dilator, which usually measures twenty or twenty-two millimetres in diameter, the examining finger is introduced.

The finger once inside the uterus, its cavity is systematically explored, and any foreign substance, new growth, polyp, remnants of placenta, or changes of any kind in the mucosa or walls of the uterus are at once felt. Their position having been accurately located, they can be readily and completely removed by means of suitable forceps or the curette.

Matthews Duncan first formulated the principle that contraction of the body of the uterus results in dilatation of the cervix, this dilatation being accompanied by marked softening of the cervical tissues. The converse of this is true—namely, that dilatation of the cervix excites contraction of the uterine muscle proper. The slow method aims at dilating the cervix by exciting uterine contractions; with the rapid method, on the other hand, we see an instance of uterine contractions excited through forcible dilatation of the cervix. This latter point is of the first importance, since it provides for the physiological control of hemorrhage after curettage. In the case of the tent a marked increase in size from absorption of fluid occurs, and this no doubt to some extent is a factor in bringing about the dilatation, but its chief mode of action is that of a foreign body which excites reflexly uterine contractions.

**Indications.**—Among the indications for digital exploration of the uterus are: 1. Haemorrhage associated with retained products of conception. In routine gynaecological work the bulk of the cases are those of incomplete miscarriage; often only a tiny piece of placental tissue may be discovered, but it is remarkable what an extensive haemorrhage this may give rise to. At other times the microscope shows a piece of retained decidual tissue to have been the exciting cause. Under this subdivision should also be placed the rare instances of malignant growths of the chorionic epithelium, or decidua malignum, which, as Williams (5) has pointed out, might be more frequently found in this country if more diligently searched for. Again, we have those not infrequent cases of death and retention of the entire contents associated with a slightly enlarged soft uterus and bloody or purulent discharge, or possibly with no discharge whatever, but a rapid decline of the general health due to sepsis. These are troublesome cases at best, and a digital exploration of the uterus is of great value in that it enables us not only to recognize the condition, but also to treat it at the same time.

2. Next in importance come those cases of persistent bleeding associated with some enlargement of the uterus, but not related to pregnancy—the cases, in short, in which one suspects the presence of an intra-uterine polyp. These patients complain of more or less constant haemorrhages, more marked at the menstrual periods, often associated with severe spasmodic pain in the abdomen. On examination the external os is found more or less patulous. In these cases the cavity of the uterus should be explored with the finger and the polyp removed by means of a suitably constructed forceps. With the curette alone one will often fail entirely to detect these new growths.

3. Submucous and intramural myomata may be detected in a similar manner.

4. Finally, there are those cases in which we meet with an offensive or purulent as well as sanguinary discharge which so frequently accompanies adenoma-carcinoma of the body of the uterus, a sloughing submucous myoma or sarcoma of the uterus. In cases of suspected tuberculosis of the endometrium and foreign bodies in the cavity of the uterus digital exploration is also indicated.

**Contraindications.**—The objection that this manipulation is dangerous, owing to its liability to produce septic infection, would certainly at first sight appear plausible. I must confess that the danger appeared to some of us a very real one, especially in connection with cases already septic from retained products of conception and other infective material. On mention of our fears to Professor Leopold he assured us that he had used the procedure in many hundreds of cases, septic and otherwise, and had experienced no bad results. He explained this freedom from infection on the theory that the tent seldom produces complete occlusion of the canal and that it is always expelled from the uterus within ten or twelve hours by muscular contractions, so that in any case a partial obstruction during this brief period could hardly materially increase or render general a local infection already present. We noticed that the tents were generally found lying in the vagina twenty-four hours after their insertion up to the fundus of the uterus, and that the odor of decomposing organic material was often decidedly offensive. Still the patient’s condition seemed good, and those we saw recovered promptly. After seeing the digital exploration of the uterine cavity in daily use, extending over a period of many weeks, in the Dresden clinic and in those of Professor Sänger (3) and Professor Zweifel, of Leipzig, who, as well as Leopold, are in the habit of employ-
ing it as a preliminary routine measure in all cases of curettage, I am convinced that in selected cases it is one of the most valuable diagnostic resources at the command of the gynaecologist. I may perhaps be allowed to cite one or two cases which especially impressed us as illustrating its value:

CASE I.—A woman, aged forty years, multipara, presented herself at the Frauenklinik in Dresden with the history of more or less constant uterine hemorrhage extending over a period of many months. She had been curetted in the usual manner some seven or eight times, but with only temporary relief from the hemorrhages, which had kept her in a feeble and anemic condition. On introducing his finger in the manner described above, Professor Leopold at once detected a polypus attached by a narrow pedicle to the posterior wall near the fundus, which had evaded the curette, but was easily removed with the forceps. The patient made a quick recovery. Leopold took occasion to cite a case which he had seen of a placental polyp which had resisted twelve ordinary curettings, but was finally recognized by the adoption of this simple procedure. Many similar cases are recorded in the literature.

CASE II.—On one occasion I saw a woman suffering from profuse menorrhagia and metrorrhagia subjected to an abdominal hysterectomy. The diagnosis of a malignant new growth of the body of the uterus had been made, but when the organ was removed and laid open only a polypus the size of a large olive, attached by a narrow pedicle to the fundus, was found to account for the hemorrhages. To be sure, in this case the tissues obtained by curettage had been accidentally confused with those from a case of carcinoma of the uterus. This case, then, illustrated not only the great danger of allowing a bottle into which curettings have been received to remain, even for a moment, unlabeled, but further demonstrates the value of a digital exploration of the uterine cavity when other means of diagnosis yield, as they would have done in this instance, either negative or uncertain results.

From these observations it seems reasonable to conclude that while the routine employment of the laminaria tent and digital exploration of the uterine cavity in every case demanding curettage, as insisted upon by Leopold, Sänger, Zweifel, and others in Germany, may be unnecessary, since the ordinary operation of instrumental dilatation and curettage, as used in the clinics of America, has proved effectual in the majority of cases, on the other hand, it should always be employed in every obscure or doubtful case of intrauterine disease, especially where the tissues obtained with the curette fail to render the diagnosis clear, and the symptoms persist after the first curettage.

THE HISTOLOGICAL STUDY OF UTERINE SCRAPINGS.

I shall not venture on this occasion to enter upon even a brief résumé of this portion of our subject, which has been so substantially and recently enriched by the writings of Winter, Ruge, A. Amann, Jr., Klein, and many others in Germany, and by the valuable papers of Hunter Robb, Cullen, Coe, Joseph Wiener, Jr., Gaylord, Williams, and others in America, but shall content myself with merely directing your attention to some recent advances in the accepted methods of the procuring, preparation, and microscopical study of curettings and excised portions of tissue for diagnostic purposes.

Method of Obtaining Uterine Mucosa.—Dr. Albert Amann, Jr., of München (6), insists upon the advantage of obtaining as large pieces of mucosa as possible for microscopical examination. In order to secure these, he advises the use of a medium-sized slightly dulled curette.

After dilatation of the cervix under full aseptic conditions this instrument is introduced to the fundus of the uterus and is completely withdrawn in one stroke with firm, steady pressure, the mucosa brought away being deposited on a bit of gauze. After the blood and mucus have been allowed to separate from the specimen, without being handled, it is dropped into a wide-mouthed bottle containing a ten-per-cent. formalin solution. These strokes with the curette are repeated in a systematic manner until the uterine cavity is completely demudded of its mucosa, after which it is swabbed out with the tincture of the chloride of iron. This is done for the purpose of cauterizing any mucosa accidentally left, as well as of arresting hemorrhage, a precaution which has not been found necessary in the clinics of this country. The advantage of having good-sized pieces of tissue to work with is readily appreciated by those who have toiled with the minute bits obtained with the small, sharp curette, which is made to describe a large number and variety of short strokes, which is not withdrawn from the uterus until the operation is completed, and reduces the mucosa to inconveniently small shreds and débris with which it is often impossible to do satisfactory work.

The bottle in which the specimens have been received should at once be labeled with the name of patient and the date. If there is no urgent demand for an immediate diagnosis, the specimens may be received in alcohol or Müller's fluid until it may be convenient to harden by the celloidin, paraffin, or other methods. On the other hand, if there is need of an immediate histological report, as in the course of an operation, in order to determine the necessity of radical procedures while the patient is still under the anaesthetic for the preliminary curettage or for the excision of tissue for diagnostic purposes, the whole process of hardening, cutting sections, staining, and arriving at a microscopical diagnosis may be completed in fifteen minutes. This was shown by Cullen (7), of the Johns Hopkins Hospital, who first published his method of making permanent specimens from frozen sections by the use of formalin in April, 1895. He describes under Process I the following steps: The specimen is received in normal salt solution and placed on the block of a microtome and frozen by means of a jet of carbonic-acid gas.

a. Place frozen section in five-per-cent. aqueous solution of formalin for three to five minutes.
b. Leave in fifty-per-cent. alcohol three minutes.
c. In absolute alcohol a minute.
d. Wash in water.
e. Stain in hematoxylin for two minutes.
f. Decolorize in acid alcohol.
g. Rinse in water.
h. Stain in eosin.
i. Transfer to ninety-five-per-cent. alcohol.
j. Pass through alcohol, then through creosote or oil of cloves, and mount in Canada balsam.

Process II is the same except that the pieces of tissue are left in a ten-per-cent. solution of formalin for at least two hours before sections are cut; they are then treated as in Process I.

It is true that Cullen, as stated in his article, has often gone through these steps and announced his histological findings in fifteen minutes, but it is difficult for even a rapid and skilled pathologist to reach satisfactory results in so short a time, and we have always felt that a simpler and shorter method was desirable. While visiting Professor Landau's clinic in Berlin in May of this year Dr. Pick, in charge of the laboratory, demonstrated to us the following method, which gives distinct, well-stained specimens. The manipulations can be comfortably made and a diagnosis reached, as a rule, in from twelve to fifteen minutes. Pick's (8) method is as follows:

a. Remove tissues from salt solution, place on ether microtome, freeze slowly, and cut.
b. Place in four-per-cent. formalin solution a quarter of a minute.
c. Remove to formalin-carmine solution one minute.
d. Transfer to water a quarter of a minute.
e. To eighty-per-cent. alcohol a quarter of a minute and remove air bubbles.
f. To one-hundred-per-cent. alcohol a quarter of a minute.
g. To mixture of two parts xylol, one part pure boric acid.
h. Place on slide and mount in Canada balsam.

There are two features in Pick's method which shorten and simplify the process of examining tissues.

1. The ether spray freezing microtome made by E. Leitz and known as Jung's Hobel (carpenter's plane), described by P. Schießlecker (12). It is simple, portable, is easily adjusted to any table, cuts good sections with automatic adjustment, and is cheap. This is certainly a very perfect apparatus and does away with the expensive and cumbersome tank of carbonic-acid gas.

2. Considerable time is gained by mixing the formalin and carmine stain; thus the specimens are hardened and stained at the same time. Although no counter-stain is used in this process, still the sections clear up well, and for ordinary diagnostic purposes, where the saving of time is urgently desired, this method has decided advantages, and is to be commended.

Cullen, in a later article in the Johns Hopkins Hosp-
Since then has noticed it occasionally. No pain. Comes on without apparent cause and frequently during sleep.

**General Condition.**—Robust, strong, and healthy looking woman; weight, two hundred and two pounds; all functions perfect; does not take medicine of any kind. Heart, lungs, and urine negative.

On October 26th patient was placed under ether, and a considerable amount of friable material was removed from the cavity of the uterus with the curette. Upon examination of this tissue by the formalin method the diagnosis of adeno-carcinoma of the body of the uterus was made.

Owing to the small size of the uterus and apparent freedom of the surrounding tissues from any involvement in the disease, together with the unusual thickness of the abdomen, Dr. Kelly decided to remove the uterus by the vaginal route. This was done in the usual manner; silk ligatures, cut long, being used and some catgut ligatures being subsequently applied to bleeding points. The whole operation occupied about an hour.

The convalescence was uninterrupted, there being no suppuration and patient was discharged in four weeks with every prospect of a permanent cure, as on laying open the uterus the cancer was found to be practically confined to the mucosa.

**Case II** occurred in the practice of Dr. Klein, of Munich, Germany, in whose hospital I was working at the time.*

Mrs. C., peasant woman, forty-three years old, xiii-para. Until June, 1897, menescs were of four-weekly type. During June and July, 1897, no menescs appeared. From the beginning of August, 1897, until April 19, 1898, she suffered with almost uninterrupted bleeding. Condition on April 19, 1898: Extremely anaemic woman, greatly weakened; external os uteri somewhat patulous; internal os closed; corpus uteri anteverted, somewhat enlarged, and soft. Dark blood is discharged from the uterus in moderate quantity.

On April 20, 1898, patient was curedet without anaesthesia. Some soft reddish-yellow fragments the size of peas and portions of thickened mucous membrane were found. After the curetting the hemorrhage ceased immediately and permanently.

The soft fragments show microscopically partly inflamed uterine mucosa, some well-preserved chorionic villi, and smaller pieces of decidua. The chorionic villi show remarkable vitality, taking the stain well, without facet vessels, the syncytium being formed partly of one layer and partly of two layers of cells. The decidua is pale, as usual, not taking the stain well; but the decidua cells are well preserved. The chorionic villi and decidua had therefore been preserved in the uterus for eight months and a half as a placental polyp, retaining their vitality unimpaired.

Dr. Klein (10) regarded this retention of vitality on the part of the chorionic villi for eight months and a half, the time which had elapsed since an undoubted miscarriage, as not only very interesting but extremely rare. Robb, however, reports a similar case in which the villi had retained their staining qualities very well nine months after the miscarriage.

I have selected these two cases from many similar ones because they show with great clearness the utter impossibility of arriving at an immediate and exact diagnosis by the purely clinical methods without a knowledge of the histological conditions present. In both these cases the subjective and objective symptoms were almost diametrically opposite. Thus Case I presented but one symptom—namely, slight bloody vaginal discharge without pain twenty years after the menopause. Her general health was perfect, and had it not been for the intelligent recognition of danger in this symptom by her physician, who had sent her to the hospital for diagnosis and treatment almost against her will, she would soon have joined the list of incurables, as the patient considered it absurd for one so healthy as herself to be sent to a hospital for treatment.

Case II, on the other hand, presented many symptoms pointing to malignant disease—long-continued hemorrhages from the uterus, with the organ somewhat enlarged and slightly softened in consistence. The patient was in an extremely anaemic, almost cachectic, weakened condition. And yet these symptoms, which clinically so strongly suggested malignancy, were proved to be comparatively unimportant by the histological examination.

**Remarks.**—Dr. Wieseuer (11), in a recent article, has gone into a careful consideration of the difficulties to be met and overcome in order to achieve successful results in this specialized branch of pathology. I think we must all fully agree with him that the gynaecologist should acquire the necessary experience himself, as is done in the German clinics, and not depend upon the general pathologists to make a diagnosis from specimens, which are often meagre, and from short, incomplete histories. The technique as outlined above is, as Dr. Pick states, not much more difficult than an ordinary uranalysis, and can be carried out in the office of the gynaecologist as well as in the laboratory. Why, then, should not this method of diagnosis be more generally recognized and employed? In obscure and specially difficult cases which require special technical knowledge and experience the specimens can easily be placed in a morphine bottle containing a ten-per-cent. solution of formalin and sent by mail or express to some well-equipped gynaecological pathologist, of whom we have many in our own country.

In conclusion, I desire to thank Dr. Kelly for permission to report Case I, and to express my obligation to Dr. Klein, of Munich, for the notes of Case II, and also for much encouragement and assistance in the practical study of this subject.

SEPTIC THROMBO-PHLEBITIS
AS A
COMPLICATION OF PERITONSILLAR ABSCESS.
REPORT OF TWO CASES.*

By M. R. WARD, M. D.,
PITTSBURGH, PA.

Peritonsillar abscess or quinsy is a common throat affection, and the almost universally favorable prognosis given by the physician in the treatment of this disease is my excuse for presenting the subject for our discussion on this occasion. In fact, so great a medical authority as Trousseau has said, "In my lengthy medical career I have never seen a death from this affection; this fact sufficiently indicates its slight gravity."

While the natural tendency is for the disease to run a favorable course, my personal experience, together with a study of the literature on the subject, has impressed me with the possible fatal complications that may arise in any case, and with the necessity of a more guarded prognosis.

Bosworth has given us by far the most complete account of the rare complications of this disease. He inclines to the belief that the most frequent fatal complication is rupture of the abscess during sleep, the pus entering the air-passages and producing death by asphyxia. The literature, however, would indicate that hemorrhage is the more common fatal complication, and that septic thrombosis, or thrombo-phlebitis, is exceedingly rare. It is to this latter condition that I wish to call your special attention.

It is only within the last decade that pathology in medicine has received a proper recognition. The intelligent physician of to-day no longer speaks of pyaemia as a disease per se, but rather as the result of a well-recognized pathological condition. This being true, I doubt not that many fatal cases of pneumonia accompanying septic processes in other portions of the body were considered simply incidental, regardless of cause and effect.

It is the exception rather than the rule for the specialist to be called upon to treat a case of peritonsillar abscess or quinsy. This disease by custom belongs almost exclusively to the domain of the general practitioner of medicine, where the treatment, if instituted at all, is purely symptomatic; surgical interference is condemned as extra-hazardous; medical, as inefficient; and the patient is usually dismissed with the comforting remark that "the abscess will rupture in a few days, when his suffering will be at an end." This is usually true, but occasionally a pneumonia intervenes, when the physician is again summoned, and the disease then receives the full measure of his attention and skill. The patient dies, and the death certificate reads, "Death from pneumonia." The peritonsillar abscess has been entirely overlooked as an aetiological factor in the death of the patient.

This, you may say with Trousseau, does not occur once in the lifetime of a physician. But when I tell you I have to report at this meeting two fatal cases of septic thrombo-phlebitis as a result of peritonsillar abscess, and both occurring within a period of four months of each other, you will doubtless agree with me that the usual favorable prognosis given in this disease should be distinctly qualified.

The evolution of sinus thrombosis, cerebral and cerebellar abscess, as a result of mastoid suppuration has been slow but sure. To-day the aurist and neurologist are fully awake to the possibilities of such complications, and, judging from the number of published cases during the last few years, the condition is not of infrequent occurrence.

An infective process in any portion of the body is liable to produce a general infection. This takes place either through the lymph or blood channels. When the infection is conveyed through the blood channels we generally have to deal primarily with a thrombosis or thrombo-phlebitis. The thrombus is usually found in the veins, in close proximity to the seat of the primary infection, though not necessarily so.

The conditions favorable to thrombosis are alterations in the blood current, change in the vessel walls, and alterations in the blood itself. Any one or all of these conditions may be present in a given case.

The slowing of the blood current from narrowing of the vessel by pressure from the inflammatory products without predisposes to the formation of thrombi.

The infection may be conveyed either along the lumen of the vessel or by contiguity of tissue through the inflammatory process. The walls of the vessel be-
come inflamed and thickened, the blood coagulates and adheres to the vessel walls, and the thrombus is thus established. The clot, when infective, does not become absorbed but soon disintegrates, producing a fluid of a greenish-brown color and abounding in living organisms. These may enter the general circulation by the disintegrated particles being swept on in the blood current, or they may spread through the walls of the vein into the neighboring parts and be again taken up by the congested vessels. Metastatic abscesses are then formed wherever the infected material finds lodgment. The lungs are most frequently involved owing to the intricate arrangement of the pulmonary circulation. Infarctions form and give rise to septic pneumonia and, not infrequently, to gangrene of the lungs. The liver, kidneys, spleen, brain, in fact any portion of the body, may become the seat of a secondary infective process.

The number of published cases of infective thrombosis or thrombo-phlebitis as a complication of peritonsillar abscess is exceedingly small. Bosworth,* in his exhaustive treatise on Diseases of the Nose and Throat, devotes a paragraph of five lines to this rare complication, and refers to cases having been reported by Rigal, Didelot, and Kiemann.

A careful review of the literature at my command adds nothing to the list referred to by Bosworth. Breton † gives a published account of these cases, which are of such importance in connection with the subject under discussion that I trust I may be pardoned for giving a brief résümé of each case:

Rigal's case: "Patient, aged twenty-two years, entered hospital November 17, 1882, after an illness of five days. The previous health had been good. The disease began with chilliness, fever, pain in the throat, followed by slight submaxillary adenitis. Examination of the throat showed the left tonsil to be enlarged and glistening. No fluctuation present. Pulse rapid. Temperature, 40.9° C.

"Next day the tonsillar abscess ruptured and discharged a considerable quantity of pus, which was followed by amelioration of pain and decline of temperature. The patient, however, remained markedly prostrated, with persistent high temperature and symptoms resembling typhoid fever.

"Death occurred on the third day after admission, having been preceded by sweats, dyspnea, and physical signs of pulmonary involvement.

"Autopsy: Both lungs studded with metastatic abscesses. Retromaxillary glands enlarged and purulent. Purulent phlebitis of the deep veins of the neck—viz., the internal maxillary, the internal jugular, and the inferior pharyngeal. The other organs of the body were found in a healthy condition."

Didelot's case: "A soldier, twenty-two years old, admitted to the hospital at Nancy after an illness of nine days. On admission, marked swelling of the right parotid and submaxillary region and of both tonsils, especially the right, so that the isthmus of the fauces was almost completely obstructed. No fluctuation in the tonsils; respiration labored; voice suppressed. A beginning jaundice.

"The symptoms grew rapidly worse, and on the second day after admission the patient died, apparently from asphyxia, though marked evidence of sepsis was present.

"Autopsy: General icterus. The tonsils, especially the right, very much enlarged. Some of the crypts contained a sanguineous pus. No distinct abscess cavity was noticed. The cellular tissues of the palate were infiltrated with pus. Uvula edematous. Posterior section of the tongue show several small collections of whitish pus along the course of the hypoglossal nerve. Purulent phlebitis of the right internal jugular vein, which condition, on dissection, was found to extend into the common trunk of the facial and lingual veins and to the tonsillar plexus.

"No metastatic abscesses of the other organs of the body. The spleen enlarged to three times its normal size."

Kiemann's case: * Under title of Tonsillar Abscess; Death from Pyaemia, the following account of the case is taken from the yearly report of the Rudolf Hospital, Vienna, for the year 1881: "R.F., twenty-two years old; single. Had applied for treatment at outpatient department on April 12th. The attack began on previous day with chill, difficulty in swallowing, and general malaise. Examination showed right tonsil enlarged, somewhat swollen, covered with grayish-yellow exudate, easily removed. In one spot a small brown crust, from beneath which, on pressure, a yellow, odorless pus escaped. Cervical glands not enlarged. At this time patient refused to enter hospital as advised.

"On April 15th patient presented himself for the second time at out-patient department suffering from high fever, and in a condition of extreme prostration. Only after long argument was he induced to enter hospital. On admission, late in the afternoon, temperature 40.6° C. During the night he was delirious and somnolent.

"Treatment: Quinine, one gramme, and ice pellets.

"Status, April 16th.—Pulse, 120; temperature, 40° C. Patient of medium height, muscular physique, yet extremely weak, somnolent, and delirious. Conjunctiva as well as skin jaundiced. Left tonsil much enlarged, without any covering of exudate, red, glistening, and tense. On pressure, a yellow pus escaped. The cervical glands on left side swollen. At the apices of both lungs faint inspiratory murmur, with full percussion note. At the right base dullness on percussion, and bronchial breathing over an extent of two fingers' breadth.

"Over the left base, for three fingers' breadth, marked dullness on percussion, with feeble breath sounds. Sputum white. Spleen much enlarged. Temperature normal; abdomen soft.

"On account of constipation was given infusion; senap; quinine, one gramme; pellets of ice. Rupture of left tonsil, whereby some yellow odorless pus was emptied. In the evening temperature 40° C. Urine, no albumin, tinged with bile.

"17th.—Delirious during night, very weak and somnolent, responded only to loud words. Marked general icterus of skin and mucous membranes. Pulse

† Théâtre de Paris, 1883. Rare Complications of Phlegmonous Amygdalitis.

* Wiener medizinische Presse, 1882, p 1520.
fluctuating between 108 and 128, yet powerful. Respiration fluctuating between 24 and 48; temperature, 39° C. From the ruptured tonsil on pressure some odorless yellow pus was discharged. The right tonsil somewhat swollen, yet without any croupous exudate, being only covered with mucus and easily removed pus. The lymph glands on left side of neck decidedly swollen. On right side, posteriorly from the middle of the thorax to the base, there was noted somewhat tympanitic, and marked increase of vocal fremitus. On the left side flatness, for three fingers’ breadth, and much weakened breathing. No expectoration. Spleen markedly swollen. Abdomen retracted and soft. Three stools discharged in bed. Urine also passed involuntarily.

"The patient died at 12.15 noon in stuporous condition.

"Autopsy: In the bronchi, sero-mucous fluid. The larynx meagre mucous membrane dark red in color, exhibiting occasional ecchymoses. The mucous membrane of pharynx extremely hyperemic and swollen. Both tonsils distinctly enlarged; in the left, an abscess about the size of a small nut. The tissues in the neighborhood of the tonsil, as well as the submucous and intermuscular connective tissues of the pharynx and the lymph glands on the left side of the neck, infiltrated with pus. In the left pleural cavity two hundred cubic centimetres of purulent exudate. In both lungs, especially in lower lobe of right, numerous small abscesses the size of a nut. The spleen about twice its normal size.

"Remarks.—The favorable prognosis, which, on a priori ground, is usually given in cases of tonsillitis and quinsy, and which, on account of the slight local and general manifestations, was given by us in the out-patient department on April 12th in this case, was here ignominiously confounded, for a rapidly developing pyemia which arose from an abscess cavity scarcely the size of a hazelnut quickly led to extensive lobular suppuration in the lungs, and, being complicated with an extensive phlegmon of the tissues of the neck, terminated in a few days in death.

"It is in this rare case of special interest that only an initial chill marked the onset of the tonsillar abscess, but the rapidly developing pyemia ran its course entirely without any chill, and only marked by very high temperature, together with an enlargement of the spleen of rapid growth."

The cases I wish to add to the above list are as follows:

**Case I.**—Mrs. M., aged thirty years, entered Mercy Hospital, Pittsburgh, on February 17th with the following history — viz.: Mother died of tuberculosis. Father, brothers, and sisters living and in good health.

Personal History.—Patient states she has always enjoyed good health until three weeks ago, at which time her present illness began. First noticed pain and soreness in the region of her left tonsil. There was no distinct chill, although she experienced chilly sensation during the first two days of her illness. The pain and swelling in the left tonsil gradually subsided, and after a lapse of three days the right tonsil became similarly affected. Besides the swelling in the throat, there was marked tumefaction and pain in the right side of the neck. She was admitted to the hospital in this condition.

Examination of the throat showed the left tonsil to be apparently in a healthy condition. Pharynx and larynx normal. The right tonsil inflamed, swollen, and having the characteristic appearance of a peritonsillar abscess. There was no exudate on the tonsil, nor could the presence of pus be detected by palpation.

External examination showed a tumefaction of the right side of the neck, extending from the angle of the jaw to the clavicle, exquisitely tender, and to all appearance like a cellulitis. The postcervical glands on the right side were enlarged and tender. The patient could not move the head without great pain, owing to the swollen and rigid condition of the muscles of the neck.

Her temperature on admission, February 17th, was 102° F.; pulse, 112; respiration, 34. Patient complained of pain in right side of chest, had a cough, and expectoration tinged with blood.

Physical examination showed a pneumonic condition of the lower lobe of the right lung, which had probably existed for one or more days. There were diarrhea, vomiting, and symptoms of sepsis. Spleen enlarged. Examination of sputum and urine negative. Patient was perfectly rational and solicitous as to the gravity of her illness. Voice whining. She took liquid nourishment with difficulty.

During the night of the day on which she was admitted there was a distinct chill, after which her temperature rose to 104° F.; pulse, 120; respiration, 40. February 18th.—No apparent change in the patient’s condition.

19th.—Had another chill, after which her temperature was 103° F.; pulse, 120; respiration, 36. Examination of the neck showed the presence of pus beneath the superficial fascia of the neck. An incision was made, and from two to three ounces of greenish-brown offensive fluid were evacuated. The cavity was flushed out with distilled water and packed with iodoform gauze. The patient continued to grow worse, had another chill during the night, and on February 20th an incision was made through the anterior tonsillar pillar and a small quantity of pus evacuated. No communication could be established between the abscesses of the tonsil and the neck.

Bronchial breathing over the middle and lower lobes of the right lung. Expectoration dark brown and frothy. Urine and feces passed involuntarily. No delirium. Patient still solicitous as to the prognosis of her case.

February 25th.—Other foci of infection in the right lung. Had chills at frequent intervals. Prostration progressive, and patient died February 26th, on the ninth day after her admission to the hospital.

Autopsy: No ieterus. Tumefaction of the neck, right side in the submaxillary region, extending as low down as the clavicle, and well behind the ear. Mastoid not involved. Periosteum of the styloid process, axis, and atlas denuded. Cellular tissues of the neck disorganized and broken down. On dissection there was found a thrombosis or thrombo-phlebitis of the internal jugular and the veins leading upward to the tonsillar plexus. A small peritonsillar abscess cavity on right side. Metastatic abscess in middle lobe of right lung. Other foci of infection in the apex and base of the right lung. Spleen enlarged to three times its natural size. Other organs of the body were found to be normal.

**Case II.**—H. K., German, aged forty-two years, and shoemaker by occupation, was admitted to the West
Abscess

On the pulse, Throat

Referred

Association, singularly or in a group, with the Klebs-Loeffler bacilli. The physiological inhibitory processes against invasion by these bacteria are in striking contrast to each other. The pyogenic cocci are resisted by phagocytosis and the distinctive end product is abscess. Coagulation necrosis is characteristic of the invasion of diphtheria bacilli and the end product is the false membrane.

When we take into consideration the frequent association of these bacteria in apparently pathogenic quantities it is very remarkable that the end processes so rarely coexist. In cases of diphtheria of the mixed infection type the initial inflammatory reaction of tissues of the throat and lymphatic system is frequently such as to lead us to expect deep suppuration or peritonsillar abscess. There is frequently undetected superficial pus formation along with coagulation necrosis, but peritonsillar abscess is a rare complication of diphtheria. In fact, phagocytosis is not a process of tissue resistance characteristic of diphtheritic infection. It occurs incidentally, and is due to bacteria associated with the Klebs-Loeffler bacilli.

It is possible that a mild diphtheritic condition may be entirely masked by a severe attack of quinsy. The clinical records of quinsy throat pareses suggest this, but certainly the occurrence is very rare, as it is not a feature of the literature of the much-studied disease, diphtheria.

Two cases exhibiting both diphtheria and quinsy at the same time came under my observation within a year and seem worthy of record.

Case I.—A farmer, aged thirty years, of temperate habits, and living in healthful surroundings, his home being about five miles from a neighboring town, consulted his physician on May 12th on account of acute amygdalitis. He was out and at work in a few days, but his throat again becoming painful, and having had an attack of quinsy a year previously, he remained at home and applied domestic remedies.

He called his physician again about the fifth day after the first visit. The right tonsil was incised and some pus evacuated. He did not improve, and the next day both tonsils and the pharynx were found to be covered with false membrane. He was given thirty-five hundred units of diphtheria antitoxin in divided injections. The membrane rapidly invaded the nasopharynx, nares, and larynx. Laryngeal stridor was apparent on the evening of the sixth day and in-

The Society of Medical Jurisprudence.—At the last regular meeting, on Monday evening, October 9th, the special order was a paper entitled Extremes in Anthropometry, with Reference to the Bertillon System, by Dr. Edward C. Spitzka.

creased alarmingly during the night. He had little fever at that time.

I saw him in consultation about noon on the seventh day. The dyspnea was so great and had persisted so unremittingly for nearly eighteen hours that he was well-nigh asphyxiated. It was impossible to inspect further than the fauces. A purulent discharge was escaping from somewhere in the throat, and an ichorous discharge came from the nares. The anterior cervical region was much swollen, and even as low as the fourth rib on the right side there was edema, suggestive of a deep phlegmonous process.

As a preliminary to tracheotomy, to which he eagerly consented, a hypodermic of whisky and strychnine was given. Our preparations for the operation were abruptly cut short by the patient ceasing to breathe, and he fell back on to the bed, apparently lifeless. He was lifted to a table and tracheotomy was quickly performed. Even the free incisions through the congested tissues and thyroid isthmus bled very little. With the tracheal dilator in place about fifteen minutes of artificial respiration restored the heart's action and respiration, and at the same time a copious hemorrhage began, which was controlled by packing with gauze, saturated with an iron solution, which he had also been taking internally.

The trachea was in the same condition as the throat—decidedly edematous and covered with diphtheritic membrane.

His temperature gradually mounted to 104° F., and about eighteen hours later he died, the immediate cause being apparently pulmonary edema. The thoracic swelling had increased, but the free incisions in the neck had somewhat relieved the swelling in this region.

The wife and two children developed typical diphtheria, were treated by antitoxine, and recovered, one exhibiting throat paresis. In this case suppuration had already taken place when diphtheritic invasion began. The disease then assumed the phlegmonous type, and there was undoubtedly septic phlebitis and rapid extension to the thoracic veins, as well as a descending cellulitis with involvement of the mediastinal lymphatics.

**Case II.**—The second case presents a general clinical history that very clearly demonstrates the vagaries of mixed infection, the different members of the family exhibiting types of infection ranging from simple sore throat to abscess and fatal diphtheria.

The eldest son of a large family had "sore throat" and remained at home for a few days. Two younger children had attacks of mild amygdalitis, as described by the mother. No physician was called. A few days later a younger daughter developed typical diphtheria and another had quinsy. About four days later the one was moribund from diphtheritic toxaemia and the other had a large peritonsillar abscess with pseudo-membrane over most of the throat. The abscess was incised and a large quantity of pus evacuated. The toxemic patient died within an hour of my first visit. The other received four thousand units of antitoxine and recovered after a very severe sickness.

A baby sister developed diphtheria of most virulent type and died within two days of the diagnosis.

This series of cases of mixed infection suggests that the virulence of the different bacteria, together with the age and natural resisting power of the patient, determines which type, false or true diphtheria or peritonsillitis, shall predominate.

In cases of this character, where pus is confined beneath tissue covered with a diphtheritic membrane, the question as to the propriety of early incisions is an important one. The more the surface is abraded the deeper will the diphtheritic infection penetrate, and the greater will be the absorption of toxine. We should be guided by ordinary surgical principles and first locate the pus accurately. It should be evacuated only through tissue already devitalized by softening, and vascular tissue should if possible be avoided.

---

**NASAL STENOSIS.**

By BURTON S. BOOTH, M.D., RHINOLÓGIST, OTÓLOGIST, PHARYNGOLÓGIST, AND LARYNGOLÓGIST TO THE TROY HOSPITAL AND TO THE LEONARD HOSPITAL.

The treatment of nasal stenosis due to deflected septa, with or without thickening of the convex side, was prior to 1886 rather ineffective and disappointing. The various methods used up to that time failed to correct the deformity, and the operator was confronted with the same conditions and resulting symptoms after the operation as he was before.

The reason why the former operations had not been successful was simply the fact that the resiliency of the cartilaginous septum had not been thoroughly broken up, and herein lies the secret of successful correction of this deformity.

During my brief career as a nose and throat surgeon I have tried nearly every operation worthy of mention. I first tried the forcible crushing of the septum with Adam's forceps and the insertion of plugs, which were worn for four weeks; I next tried the method of pushing the septum into the concave nostril and transfixing it with a long pin; I further used the stellate punch, removing the most prominent part of the obstructing septum. Subsequently I resorted in turn to the multiple-incision operation, the snaring operation, and the electro-cautery operation, and each time I was chagrined to find that my efforts had been fruitless and that the original deformity, with its dependent symptoms, still existed.

After being disappointed in the failure of these various methods to correct this condition, I used the nasal saw as recommended by F. H. Bosworth, of New York city, removing as much of the septum as could be done without producing a perforation. I was contented to use this method, as I must say it had given me fairly good results, especially where I had corrected by means of the electro-cautery or the snare any existing hypertrophy of the turbinate tissue.

Until some four or five years ago I made trials of the operation recommended by Dr. Morris Asch, of New York city, but not having a thorough conception of his...
method and technique of operating my labors were of no avail and I did not get a good result.

Some few months after my failure with this operation I had occasion to visit New York city, and I took the liberty to call on Dr. Asch, who, after explaining his method thoroughly to me, kindly invited me to witness an operation which was to be done by Dr. Emil Mayer at the New York Eye and Ear Infirmary that afternoon. I accepted the invitation, and was very much pleased that I had done so, for I readily saw that his success depended upon the manner in which he operated, and that my failure had been due to imperfect technique.

Since that time I have performed Asch's operation to correct this deformity a number of times and have been gratified with the results. My method of operations, which I believe to be the same as his, is as follows:

First. It is necessary to select the cases for operation in order to be successful, as I believe this operation to be intended to relieve deflection of the cartilaginous septum only; but, fortunately, deflection of the bony septum, except for its anterior portion, is not common, so that this operation will suffice in the majority of cases. I myself prefer to operate in a hospital, where the patient can be prepared for a day or two before the operation, and where he can be under the constant observation of a trained nurse for a few days following it. The operation should be done under an anesthetic. The instruments used are a pair of straight and a pair of angular cutting scissors recommended by Dr. Asch, a compressing forceps similar to the Adam's forceps, a blunt separator for separating any adhesions which may exist between the convex portion of the deviated septum and the inferior turbinate body, and some tubular splint made of hard rubber. These instruments should be thoroughly sterilized and the nostrils thoroughly cleansed by means of cotton wound on applicators dipped in some antiseptic solution. After the nostrils have been thoroughly cleansed the patient is placed in a position with the head extending over the end of the table to prevent so far as possible the blood running down into the larynx, producing coughing which might interfere with the operation; under full illumination the separator is then introduced into the stenosed nostril and any adhesions which may exist are broken down. The scissors are now introduced parallel to the floor of the nose, the sharp blade entering the nostril on the concave side of the septum and the blunt blade entering that on the convex side; the blade should be at right angles to the septum, and over the most dependent part of the deflection. After being sure that the blades are in the right position, the handles are firmly closed and the sharp blade passes through into the opposite nostril with a distinct snap; the scissors are now opened and withdrawn, and are immediately reintroduced in the same manner as before. This time the blades are made to cross in a vertical direction the first incision at its centre and as far as possible at right angles, thus making a crucial incision with four segments. The operator now introduces his finger into the stenosed nostril, pushing it through to the opposite nostril, at the same time breaking each segment at its base, thus destroying the resiliency of the septum; and I might say here that this is the most important part of the operation, for in destroying the resiliency of the septum it makes it impossible for it to resume its old position. An Adam's straightening forceps is now introduced, one blade into each nostril; the septum is grasped between its blades and by a rotary motion is more thoroughly broken up and brought into the median line; at the same time, by holding the forceps in this position, thus compressing the septum, the hemorrhage is somewhat checked, and I believe that more can be accomplished to check the hemorrhage by this method than by the spraying of solutions into the nose. After the hemorrhage is somewhat under control, a firmly fitting hard-rubber perforated splint is placed into the nostril which was stenosed and a smaller splint is placed into the opposite nostril. The pressure of these splints will have a tendency to check the remaining hemorrhage; still, there may be oozing for some time after the operation. It may be necessary to hold the splints in place by means of a strip of rubber adhesive plaster.

The patient is placed in bed, where he should remain for a few days, and for a few hours should be fed in the same way as any patient who has taken an anesthetic.

When he recovers from the bad effects of the operation and the anesthetic he should have a light diet for the time he remains in bed, after which he may have ordinary diet.

The splint should be removed from the non-stenosed nostril after twenty-four hours and the nostril should be washed out. Twenty-four hours subsequently the splint in the stenosed nostril should be removed, the nostrils thoroughly washed out with an antiseptic solution, and a fresh sterilized splint of proper size introduced; this splint should be removed at least once a day by the patient, who can easily be taught to remove and insert the tube with little or no pain. The nostril should be thoroughly washed out by some saline solution each time the splint is removed. I use a tablet made by Frazier, composed of sodium salicylate, two grains; sodium chloride, twenty grains; spirits of camphor, three minimis and a half, to make this solution. One tablet added to half a cupful of warm water is the proper strength of the solution to be used. This solution makes a bland and cleansing mixture. The patient should be instructed not to blow the nose for a couple of minutes after spraying.

The splint should be thoroughly cleansed before it is reintroduced. The patient should be seen a couple of times a week by the operator and the splint should
be worn for at least four weeks, after which it may be left out permanently.

The swelling and inflamed condition of the mucous membrane, which result from the wearing of the hard splint, usually succumb to the frequent flushing of the parts with saline solution. If not, I use a four- to six-per-cent. iodthyl ointment.

It may be necessary to remove under cocaine any thickening which may be produced by the overlapping of the segments, by means of a saw. This is a very simple procedure, and is not often necessary.

As to the preference of the splints to be used, I will say that there are many different varieties on the market, most of which are good, and the operator will have to use his own judgment in selecting the splints to be worn. I have many different kinds, and commonly use the one that the patient complains the least of.

I may state that the success of the operation does not depend on the kind of splint to be worn, but on the manner in which the operation is performed and the attention given to the parts by the operator and the patient subsequent to the operation.

The splint can be worn with little or no discomfort and without attracting any attention, thereby allowing the patient to attend to his duties.

THE COURSE AND PROGNOSIS OF CHRONIC SPINAL NEURITIS.

By ARTHUR CONKLIN BRUSH, M.D.,
ASSISTANT NEUROLOGIST TO THE KINGS COUNTY AND BROOKLYN EYE AND EAR HOSPITALS; CONSULTING NEUROLOGIST TO THE BROOKLYN CENTRAL AND BEDFORD DISPENSARIES.

Although chronic neuritis is a well-recognized affection, it is usually described together with the acute form; and so much attention is devoted to the latter that but an imperfect impression of the importance of the former is conveyed. Nevertheless it is a condition which, although it does not often directly effect the death of the patient, yet causes him to suffer from intense pain for months or years, and frequently leaves him with one or more of his limbs wasted and partially or completely paralyzed. Fortunately, the chronic form is not as common as the acute. In one hundred consecutive cases of all types of spinal neuritis which have come under my care, I find this form occurring in only eighteen per cent.

Chronic neuritis may be secondary to the acute form, or it may be chronic from the beginning and following such causes as injury, alcohol, the metallic poisons, tuberculosis, malaria, and the different forms of rheumatism and gout. In my own cases three followed the acute form, eight were due to chronic alcoholism, two to injury, and one each to tuberculosis, rheumatism, puerperation, arsenic, and lead.

As in the acute form, we may find the inflammation confined to one nerve or a group of nerves; or it may involve a large number of nerves simultaneously or consecutively. The symptoms develop slowly and insidiously without constitutional disturbance. Pain is often an early and prominent symptom—a pain which is referred to the course of the nerve, and which is of a dull, burning character, with frequent exacerbations. With or without the pain there are often subjective sensations of numbness or burning in the skin supplied by the affected nerves. All forms of sensation are usually diminished in the affected part, or with the loss of tactile sensation there may be increased sensitiveness to pain. The affected nerve trunks are tender on pressure, and any movement which puts them on the stretch causes pain. At the same time there is a gradual loss of power associated with flaccid atrophy of the muscles supplied by the affected nerve; and this may pass into complete paralysis with almost total disappearance of the muscle substance, leaving rigid atrophy, contracture, and deformity. At times there may be fibrillary tremors or cramps in the affected muscles. The tendon reflexes are early diminished and frequently lost. The well-known electrical reactions of degeneration appear early, and all reaction is frequently lost. Trophic affections of the skin, bones, and joints are also not infrequent.

The pathological changes found in the affected nerves are similar to those of the acute form, but differ from them in that there is less tendency to the destruction of the axis cylinder and an increased one to the formation of a permanent hypertrophy of the perineurial and interstitial connective tissues with a thinning of the myelin sheath, thus producing permanent compression and irritation of the affected nerves. It will be seen that these changes are of a permanent character, leaving the nerve partially or completely destroyed, and in some cases they may extend to the spinal ganglia or the cord itself.

 Clinically we can divide these cases into those in which the inflammation is confined to one or more nerves in the arm or leg, and those in which it involves a large number of nerves in different parts either simultaneously or consecutively. In my seven cases, in which the neuritis was confined to the arm, the disease was of the chronic type from the beginning, and due to alcohol in three, to injury in two, and lead in two. All began with pain referred to certain nerves, followed by loss of power and atrophy in the muscles supplied by them; and this condition gradually spread to other nerves, often showing the peculiar involvement which indicates disease of the roots of the brachial plexus. In my cases of this type the motor symptoms have been much more marked than the sensory, and in all but one the patients have been left with decided weakness or complete paralysis associated with marked atrophy of the affected muscles. Of this class the following is a good example:
Man, aged twenty-nine years, a plumber. Present trouble began two years ago with neuralgic pains in the right arm and hand, followed by loss of power and atrophy associated with fibrillary twitching in the ball of the thumb, which spread to the forearm and shoulder. On December 20, 1892, his condition was found to be as follows: Thumb extended and adducted, second and third fingers flexed, and fourth and fifth fingers extended. Complete paralysis with marked atrophic rigidity of all the muscles of the hand and forearm, the triceps, deltoid, supraspinatus and infraspinatus muscles. Tactile anaesthesia with increased sensitiveness to pain over the back of the hand and forearm, and tenderness on pressure over the nerve trunks in the arm. At the present time there is still complete atrophic paralysis of the intrinsic hand muscles, the deltoid, and scapular muscles.

In the cases in which the neuritis is confined to the lower extremity, it most commonly involves the sciatic and its branches. In my six cases, two followed the acute form and the others were chronic from the beginning. Of the latter, four were due to alcohol, one to injury, and one to tuberculosis. In all these cases the lesion was not as closely confined to one limb as in the arm type, but existed to a slight extent in its fellow. Pain is a much more marked symptom in the leg than in the arm type. At first it is paroxysmal, but after a time it becomes continuous, with severe exacerbations. Soon motor symptoms develop, as in the arms, and are frequently associated with cramps in the calves. In the cases which I have seen the prognosis as to the motor symptoms has been much better than in the arm type; but, on the other hand, they are usually left with frequent and severe attacks of pain in the affected nerves.

The following is a good example of this type:

Man, aged fifty-seven years. Three years before I saw him he began to have severe neuralgic pains referred to right hip, back of right thigh, and right leg. Two years later he noticed that his right calf was becoming smaller and that he was unable to lift the toes of that foot from the ground. Severe cramps also occurred in the right calf at night. On May 5, 1893, there were found marked foot-drop on the right side, with well-marked flaccid paralysis of all the leg muscles, and a similar but less marked condition in the extensor quadriceps. Loss of all forms of sensation in the foot and leg, with tenderness over the sciatic nerve. In this case the motor symptoms have slowly improved, leaving a slight atrophy and loss of power, but the severe pains continue at the present time. I should have added that in both this case and in that of the arm type the galvanic reactions found in degenerative conditions were present, and that in the former the knee-jerk was diminished.

In the six cases of the chronic form of multiple neuritis, which I have recorded, the condition has been chronic from the beginning, and due to alcohol in three, and in the others to parturition, arsenic, and rheumatism respectively. Unlike what occurs in the acute type of the disease, the inflammation does not affect simultaneously the nerves of both upper or lower limbs or all four together, but appears at first as a local condition irregularly involving the nerves of one limb, and then, after some time, those of another limb, not necessarily the mate to the one first involved, or even on the same side of the body. Neither is there any relationship between the nerves involved in the different limbs; so that, while the acute type is markedly symmetrical, the chronic form is markedly irregular. After the disease has appeared in the nerves of a limb it may remain confined to certain ones or slowly involve all the nerves of the member. The symptoms are the same as in the local types, but pain is not, as a rule, prominent. The prognosis has in my experience been very bad, for three have died, one has been left with complete paralysis and atrophy of his arms and legs, and two have terminated in locomotor ataxia. Of this condition the following is a good example:

Woman, aged forty-one years; rheumatic history. Her present condition began seventeen years ago with gradual atrophy of the thenar and hypothenar eminences, accompanied by weakness and fibrillar twitching. This condition slowly spread to the forearm and shoulder, and three years ago appeared in the extensors of the right foot and leg. On June 19, 1896, her left thumb was found to be flexed across the palm and her left little finger extended and abducted. There was complete atrophy of the thenar and hypothenar eminences and of the flexor and extensor carpi ulnaris, and also paralysis. There was a similar but less marked condition in the left deltoid, right thenar and hypothenar eminences, and extensors of the right foot and leg. There was loss of tactile sensation with hyperesthesia to pain over the palmar surface of the left hand, and pain on pressure over the nerve trunks in all the limbs. The atrophy and consequent paralysis have since that time slowly spread in an irregular manner until at the present time the patient presents a complete atrophic quadriplegia with flexor contractions. That locomotor ataxia sometimes begins as a neuritis of the posterior nerve roots is now a well-established fact, but that it may begin as an ascending neuritis is denied by some. The termination in two of my cases would support the theory that it may so arise, and I therefore offer their histories in support of it.

Man, aged sixty-seven years. He has had three attacks of neuritis, each following exposure to cold and wet. Absolutely no history or physical evidence of syphilis. His first attack occurred seventeen years ago, and involved both legs. The second attack occurred one year later and involved the left arm. The present attack began nine years ago with pain and numbness in the feet and legs, followed by pain, gradual loss of power, and atrophy in all the muscles of the lower limbs. On March 19, 1895, there was found a partial paralysis of all the muscles of the lower extremities, most marked in the extensors, partial loss of tactile sensation, with delayed sensation of pain, tenderness over the nerve trunks, and absence of knee-jerks. By November, 1896, the paraplegia had improved so much that he was able to stand and walk a few steps; but since that time he has also developed static and locomotor ataxia, loss of knee-jerks, vesical incontinence, lightning pains in the trunk and limbs, attacks of diplopia, Argyll Robertson pupils, and girdle sensations.

The second case is that of a man, aged thirty years.
No history or physical evidence of syphilis. In 1894 he was under my care for a severe attack of acute multiple neuritis, from which he recovered. He again came under my care in November, 1898, suffering from loss of power in the extensors of the foot, associated with loss of tactile sensation and hyperesthesia to pain in the feet and legs. He recovered his motor power, but continued to have attacks of severe pain in the lower limbs, and on October 8, 1898, he was first noted as ataxic in his gait. There were then found to be present well-marked static and locomotor ataxia, Argyll Robertson pupils, and absence of knee-jerks. The attacks of severe pains still continue, as do the disturbances of sensation in the feet and legs.

It will be seen, then, from the histories of these two cases that we have a clear history of neuritis in which the patients after some time slowly developed the symptoms of locomotor ataxia; yet the most careful investigation was unable to show any evidences of syphilis or other usually assigned causes for the latter condition. If we are to consider the occurrence of the locomotor ataxia not as an accident but as a sequel of the neuritis, its appearance is easily explained by the inflammatory process passing upward by the posterior nerve roots to the posterior columns of the cord.

GANGRENE OF THE LUNG.

WITH A REPORT OF TWO CASES.

By A. I. LEVINGS, M. D.,

MILWAUKEE,

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF SURGERY AND CLINICAL SURGERY IN THE WISCONSIN COLLEGE OF PHYSICIANS AND SURGEONS; SURGEON TO ST. JOSEPH'S HOSPITAL AND TO NOTRE DAME INSANE; CONSULTING SURGEON TO THE MILWAUKEE COUNTY HOSPITAL FOR THE INSANE.

Gangrene of the lung is seldom a primary disease, but rather the sequence of some other diseased condition. It is comparatively of infrequent occurrence. Tyson states that in three per cent. of the deaths from pneumonia gangrene of the lung is present. In sixteen hundred and twenty-one consecutive autopsies the Middlesex Hospital Fowler found gangrene of the lung in but seven cases.

There are certain conditions which predispose patients to pulmonary gangrene, as, for instance, anything which lowers the vitality or produces general debility or interferes with the pulmonary circulation. It is especially likely to occur in diabetic patients, and to follow pneumonia where the vessels become so engorged that the circulation is seriously interfered with, or at some points completely arrested. Troops suffering from scurvy have frequently been attacked with pulmonary gangrene.

Gangrene may also follow injuries and wounds of the chest, both penetrating and non-penetrating, the inspiration of foreign bodies and of septic material from septic processes in the mouth and throat, or be embolic in character, the result of septic processes situated elsewhere in the body, or be caused by tumors making pressure upon the pulmonary circulation. It occurs occasionally in the insane and in those suffering from bulbar paralysis. It is especially liable to follow septic processes situated within the chest wall, as in bronchectasis, septiceptic, or tuberculosis, and empyemic processes.

In considering the symptomatology of pulmonary gangrene one must remember that, as it is a secondary process, its symptoms will be more or less intermingled with and masked by those of the disease which has preceded it. In fact, gangrene of the lung has no symptoms which are absolutely distinctive or pathognomonic, and none which are even suggestive, until the gangrenous area has opened into a bronchus. In common with other acute affections of the lungs, there are pain, disturbed respiration, fever, and cough, the last often paroxysmal and most intensely harassing.

With the opening of the gangrenous area into a bronchus, hemorrhage occurs, slight or severe, and a foetor of the breath and expectoration which is intense, penetrating, horrible. With this foetor of the breath there may occur a sweetish, most disagreeable, and disgusting taste, often more distressing to the patient than the breath.

The foetor is most intense during the act of coughing. The sputum has a dirty gray, a brownish green or blackish color and is usually streaked with blood; or the amount of blood expectorated may be considerable or even alarming.

The sputum, if collected in a glass jar and allowed to stand for several hours, forms in three layers. The first is mucopurulent in character, the second serous, and the third or lower layer is thick, heavy, and consists of pus, blood, crystals of fat, the various pyogenies, pathogenies, and saprophytic micro-organisms, and elastic tissue, with fragments of lung tissue in large or small sloughs.

While the foetor of the breath and expectoration is most suggestive of pulmonary gangrene, it must be remembered that occasionally a like foetor occurs in septiceptic bronchitis, in bronchectasis, and in tuberculous cavities.

The history of the case would aid very materially in distinguishing these conditions, as well as the absence microscopically of fragments of lung tissue or any considerable amount of elastic fibres. The condition must also be distinguished from abscess, although the treatment may be the same. Abscess has not the horrible foetor of gangrene, neither does the expectorated material correspond in color, nor is there the same likelihood of hemorrhage.

A reliable diagnosis of pulmonary gangrene will depend upon the history of the case, the symptoms, the characteristics of the sputa, and a thorough physical examination of the chest.

Primarily there will be circumseribed dullness, providing the area affected is of sufficient size and super-
officially situated, with bronchial breathing and more or less of râles.

With the breaking down of the area there will be the signs and symptoms of a cavity. The diagnosis and location of a cavity are of the very first importance. If the area has approached or implicated the costal pleura, there will be severe pain with the friction sounds of a pleurisy. Upon percussion a portion of the dull area will have changed to tympanites. In one of my cases the percussion note was observed to alternate over a circumscribed area between dullness and tympanites. After a severe fit of coughing and the expectoration of a quantity of pus and broken-down material, the area would, upon percussion, be low pitched and markedly tympanitic. If the patient had had no severe cough for twenty-four or thirty-six hours, the cavity would become filled with pus and blood, the air forced out, and the percussion note be dull.

Upon auscultation cavernous or amphoric breathing, cavernous or amphoric voice, and gurgling râles or a metallic tinkling may be heard.

If the cavity is in full communication with a bronchus, the percussion note will be higher with the mouth open than with it closed (Wintrich).

Gerhardt has called attention to the fact that if the cavity is longer in one direction than another and contains fluid, change in the patient’s position, by allowing the fluid to gravitate in different directions, will change the pitch.

Wintrich’s interrupted change in pitch is considered pathognomonic—that is, with the mouth open, a rise of pitch is noticed upon percussion only in a certain position, as, for instance, lying upon one side or sitting up.

By a careful consideration of the history and symptoms, and a thorough examination of the chest, the presence or absence of a cavity may usually be determined.

In a few cases of gangrene of the lung recovery will take place under the expectant treatment. In these cases the gangrenous area will be small, well circumscribed, and will have opened freely into a bronchus. But in the great majority of cases pulmonary gangrene will require surgical interference. Réclus says that but thirty per cent. recover without operative interference, and that from seventy to seventy-five per cent. of those operated upon recover. Operation is indicated when the cavity is of any considerable size; where it is not well drained through a bronchus; where there is severe or alarming hemorrhage; where the fœtid expectoration is exhausting the patient; or where there is a harassing cough, irritating diarrhœa, and commencing hectic.

If the process is slight and deep seated, operation may reasonably be delayed for a few days, provided there are no contraindications, with the expectation that the process will become superficial and cause adhesions of the pleural surfaces.

The location of the gangrenous area must be determined as nearly as possible by a physical examination of the chest. Then this finding is corrected, if necessary by the use of the aspirating needle. One may succeed with the first puncture, or only after several punctures, or may utterly fail. Success with the needle will depend largely upon the size of the gangrenous area, its nearness to the surface, and upon the presence of adhesions. If the area is small or deeply situated, or even superficially situated, without adhesions, and with some pleuritic effusion, failure to locate the area is most likely to occur.

It may be possible while making these punctures to determine the presence or absence of adhesions. If a pleural cavity exists, this can be determined, and if the needle moves synchronously with respiration, adhesions are probably not present.

If the gangrenous cavity is located and adhesions are present, it may be cut into with or without the resection of a rib. If adhesions are absent, the pleural surfaces may be united by a row of sutures around the gangrenous area, or the general pleural cavity may be shut off by an iodoform-gauze packing. The latter method is recommended by Carl Beck, and has been practised by myself with excellent results in one case. Clinical experience has shown that not infrequently the surgeon fails, even after repeated efforts, to locate the gangrenous area with the needle. In these cases multiple resection of ribs should be practised through a perpendicular incision in the axillary or post-axillary line and the lung palpated. That this can readily be done I know from personal experience in a number of cases. The softened gangrenous area can be recognized by the hard, hepaticized portion of lung which surrounds it. The danger incident to opening the chest on account of collapse of the lung has been, I believe, overestimated.

Pleuritic adhesions or pulmonary hepatisation will prevent the lung in part or wholly from collapsing, and even should collapse take place to a lesser or greater degree, reexpansion will soon occur on account of the dressings protecting the lung from external air pressure.

After the lung has been exposed and the gangrenous area localized, it is well to follow Sonnenberg’s rule in opening it: “If the tissues over the cavity are hard, divide with a knife; if soft, with the Paquelin cautery.”

The subsequent treatment of the gangrenous cavity is of the first consideration. It is usually filled with pus and the débris of the sloughing portion of the gangrenous lung. It should be cleansed, and this can be done with ease with a gentle stream of warm carbolized water, provided the patient is so placed that external drainage is perfect. This is not likely, at most, to do more than excite some coughing. After thorough cleansing, to be done daily, the cavity should be tightly packed with iodoform gauze. Carl Beck inserts a narrow strip of gauze, but this, I think, is not sufficient to control hemorrhage, which has been frequent in these cases and, in at least half a dozen, fatal. The iodoform
gauze, if properly used, not only prevents haemorrhage, but has a favorable effect upon the gangrenous area.

The dangers and complications which may arise during, or as the result of, surgical interference are:

1. Suffocation. In any patient having a cavity more or less filled with fluid and in direct communication with a bronchus, there is a real danger of suffocation during the administration of an anaesthetic.

2. Some of the septic material may be inspired, setting up a fetid bronchitis.

3. The danger of shock and of subsequent exhaustion is very considerable.

4. Haemorrhage, both intercostal and pulmonary, may occur.

5. Septic infection of healthy lung tissue as the result of the punctures may take place.

6. Operative interference may be the cause of secondary rapid sloughing, and gangrene of the lung may follow interference when adhesions are absent or insufficient.

7. Pneumothorax and pyopneumothorax.

The points I desire to make are these:

1. All cases of pulmonary gangrene which are progressive and not absolutely diffuse should be operated upon.

2. The gangrenous area should be localized by physical examination, aided by the use of the aspirating needle, and, if necessary, by multiple resection of ribs.

3. In the absence of pleuritic adhesions, the general pleural cavity should be shut off either by a gauze packing or by a row of sutures.

4. After thorough opening and free drainage of the gangrenous cavity it should be daily cleansed by gentle irrigation.

5. The cavity should be tightly packed with iodoform gauze.

**Case I.**—Mrs. M., aged fifty-five years, of spare figure, never strong or very well. Had pleuro-pneumonia in September, 1895; it ran the usual course, subsided, and then came a return of fever; lower portion of right lung dull; at the end of the third week foetid breath and expectoration; signs of a cavity. An aspirating needle was used; result negative. Operation: Portion of ninth and tenth ribs resected, pleural cavity opened; no adhesions; a few ounces of seropurulent fluid evacuated. Lung did not collapse very appreciably. Lung palpated; a softened area surrounded by hepaticized lung discovered; aspirating needle used, which entered gangrenous cavity; area packed around with iodoform gauze. A long artery forceps was thrust into cavity and the tract dilated, then a medium-sized drainage tube inserted. Patient developed a most severe bronchitis; drainage poor; recovery very slow and somewhat imperfect; wound healed after four months.

**Case II.**—Mr. W., aged fifty years, diabetic, was taken with pleuro-pneumonia, right side, November 23, 1898; fever subsided on the seventh day, then returned; circumscribed dullness in post-axillary line beneath eighth and ninth ribs. On December 2d patient complained of a disagreeable and most disgusting taste, sweetish in character. This continued as long as the fetor of the breath, which manifested itself the following day. On the morning of December 3d the nurse spoke of the patient's breath being offensive. The same night there was a violent fit of coughing with the expectoration of much horribly offensive material very dark in color, with which there was a quantity of fresh blood. The paroxysms of coughing and raising of considerable fetid material mixed with blood occurred every twenty-four to thirty-six hours. It was noticed that the centre of the previously dull area became tympanitic after the fits of coughing and raising, to again become dull if but little was expectorated for twenty-four hours. The case was a progressive one; the cough became more harassing, the amount of blood and material expectorated increased, and the patient grew weaker. On December 17th the cavity was located by the first puncture with the needle, a portion of the ninth rib resected, and the cavity freely opened, adhesions being present. The cavity was filled with pus and detached and undetached sloughs of lung tissue. It was about an inch and a half in diameter and six or seven inches long, running upward and inward in the lung. The cavity was gently washed out and two drainage tubes inserted. Upon the third day following the operation there was a slight haemorrhage from the wound. This increased daily, and upon the sixth day the tubes were removed and the wound lightly packed with a strip of iodoform gauze. Upon the seventh day there was a most violent haemorrhage, the patient coughing up in a few moments at least a pint of bright-red blood; the dressings at the same time being completely saturated. The bleeding ceased only when seemingly there was no more blood to lose. When the patient was slightly recuperated the dressings were removed and the cavity was firmly packed with iodoform gauze by using a long uterine probe. Upon the second day, when the gauze was withdrawn, fresh arterial blood in a large stream was seen to issue from the cavity; the wound was again quickly and firmly packed; this was repeated daily, and the patient made a perfect recovery. The wound healed in two months and a half.

**THE RELATION OF THE STOMACH TO THE NON-PREGNANT UTERUS.**

By FRANK H. MURDOCH, M.D., PITTSBURGH, PA.

It is well known that female patients suffering from the various forms of stomach trouble are frequently much worse during the menstrual flow. This is true in cases where the menses are painless as well as in patients suffering from dysmenorrhoea, and in hyperchlorhydria as well as in hypochlorhydria. As examples showing how the stomach may be disturbed at the menstrual period during the existence of exactly opposite conditions, I will cite the following cases:

**Case I.**—Miss K., aged twenty-five years, came to me July 28, 1898. One year previous she had an attack of gastritis, which confined her to bed five weeks, and to the house for nearly six months.

**Present Condition.**—Looks pale and thin; feels weak and languid; has pain immediately after eating, lasting an hour; a great deal of bloating and belching; attacks
of vertigo every day, so that she has to grasp something to keep from falling. The distress after meals, as well as the bloating and belching, are greatly increased during the menstrual period. The menses are painful only during the first day of the flow.

Examination.—Chest intact, excepting reduplication of the first mitral sound; liver normal; stomach reaches navel; whole of gastric region very sensitive to pressure. Free HCl, 32; acidity, 60.

Case II.—On May 15, 1899, Miss H., aged twenty-six years, stenographer, came to me with the following history: Four years ago she was taken suddenly ill with vomiting and severe headache. Following this attack the headache became almost continuous, and finally compelled her to give up work.

She continued to be very nervous, however, and could not see any one, as excitement of any kind caused pain in the head. She had an empty feeling in the stomach two or three hours after meals, which was relieved for a short time by eating; regurgitation of food, sometimes sour, sometimes bitter. Appetite always good, bowels regular, slept well.

Present Condition.—Spits out sour fluid mixed with food; still has headache if she gets tired or excited; is unable to work; appetite good, bowels regular, sleeps well, looks pale, but has not lost weight. For two days before the menses appear, during the flow, and for several days after it disappears, she has nausea, pyrosis, regurgitation of food, belching, and headache, to a much greater extent than during the intervals between the periods; and in addition to these symptoms she experiences a sense of extreme lassitude and great weakness, so that she practically is confined to bed, although at other times a walk of a mile, while causing fatigue would not produce exhaustion.

Examination.—Chest intact, liver normal, stomach reaches navel, urine normal, free HCl absent.

The two cases next to be cited were patients suffering from dysmenorrhoea the result of gastric ulcer.

Case I.—June 1, 1898, Miss H., aged seventeen years, applied to me for treatment. For six months she had suffered from dysmenorrhoea to such an extent that she was obliged to have hypodermics of morphine in order to obtain relief. Finally she applied to a competent gynaecologist, who, upon careful examination, failing to find any pelvic trouble sufficient to account for the pain, kindly referred her to me for further examination. She stated that six months before, or about the time she began to suffer from dysmenorrhoea, she lost her appetite, her bowels became constipated, and she had great distress immediately after meals, accompanied by bloating and belching.

Examination.—Chest intact, liver normal, one exceedingly sensitive circumscribed spot midway between the xiphostic cartilage and the navel. Haemoglobin, sixty per cent. The diagnosis of gastric ulcer was made, and the patient put upon liquid diet and bismuth. On June 14th menstruation came on a few days before the usual time and absolutely without pain, much to the surprise of the patient.

Case II.—On March 4, 1899, Miss C., aged nineteen years, came to me with the following history: In September, 1897, after dinner at noon she was seized with severe pain in the gastric region accompanied by much bloating and belching. This lasted all the afternoon, the bloating rather longer than the pain. She gradually recovered from this attack and felt very well until a few days after Thanksgiving, 1898, when she had a second similar to the first, experiencing great pain in the gastric region, with bloating and belching. Since that time she has had attacks every week, and last week had three. During those most severe, which last usually about two hours, her hands and feet grow cold, and she has been obliged to unfasten her clothing and lie down. She has never vomited, but after the most acute attacks of pain the stools have been dark.

Present Condition.—She has distress in the stomach immediately after eating, which she describes as a cramping pain referred to the lower end of the sternum, with much bloating and belching. She looks pale, but not thin, although she has lost twelve pounds in weight since Thanksgiving. Her appetite is good, she sleeps well, her bowels never move without a laxative. In September, 1897, or about the time she had the first attack of stomach trouble, she began to have painful menstruation, the pain being so severe that she was obliged always to take an anodyne to obtain relief.

Examination.—Chest intact, liver normal, haemoglobin sixty-five per cent. There is one small, circumscribed spot of great tenderness just below the xiphostic cartilage, with a corresponding tender spot to the left of the ninth dorsal vertebra. Gastric ulcer was diagnosed, and the patient put upon liquid diet and bismuth. On March 24th menstruation came on, and, for the first time in two years, was absolutely without pain.

These cases serve to show that menstruation, whether painful or not, may act as a disturbing element in gastric disorders, and also that in some cases dysmenorrhoea may be caused by chronic ulcer of the stomach. The direct cause of the painful menstruation in these cases must have been the irritation produced by the presence of solid food in the stomach, for both the attendant anaemia and the circumscribed spot of tenderness were present in each case after the dysmenorrhoea had disappeared.

Therapeutical Notes.

Napelline in Neuralgia.—Dr. Grognot (Journal des praticiens, September 2d) obtained a success in a case of obstinate neuralgia which had resisted acanitine by the following prescription:

R Napelline ........................ ¼ grain;
Extract of licorice, q. s. to make one granule.

M.
One to be taken every two hours.

For Constipation.—Riforma medica for July 4th attributes the following to Buehrerlon:

R Podophyllin, ½ of each 6 grains:
Euonymus; Extract of belladonna 3 "
Extract of hydrastis canadensis. 15 "
Medicinal soap .......................... 30 "

M.
For twenty pills. One to be taken at the evening meal.
THE NEW YORK MEDICAL JOURNAL.
A Weekly Review of Medicine.
Published by D. Appleton and Company
Edited by FRANK P. FOSTER, M.D.

NEW YORK, SATURDAY, OCTOBER 14, 1899.

THE CHICAGO MEETING OF THE MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

It is always considered more or less venturesome for a scientific body whose membership is scattered to hold a meeting in a great city. The diversions are so many and so powerful that the members are apt to be drawn away, many of them, from the purposes of the gathering. It is therefore much to the credit of the Mississippi Valley Medical Association that the meeting held in Chicago last week showed not the least flagging of interest in its own work, notwithstanding the numerous and potent attractions of the city, heightened immensely at the time by the preparations for the autumnal festival and this year additionally enhanced by the presence of the chief magistrate of the republic, of the governor-general of Canada, and of the Mexican ambassador. The visitor from almost any other part of the country might well have been pardoned if all these seductions had lured him away from the halls in which the sessions were held and made him oblivious for the time being of his duties to the organization. It is pleasant to be able to record that they had no such effect. Interest in the proceedings of the meeting met with no eclipse; the members were constantly on hand to read the papers for which they had been set down, to join in the discussions, or to digest and assimilate that portion of the doings which commanded itself to their judgment.

It is a customary thing for medical societies that are national in composition or, as in this instance, draw their members from a territory which, if not coterminous with the entire domain of the country, is still vast, which hold only annual meetings, and which limit the president's tenure of office to a single year—it is customary for such societies to choose the new president from the profession of the place in which the next meeting is to be held. This custom, however, has no great weight as a precedent, and it is not strange that the association, while resolving to hold its next meeting in Asheville, elected as its president for the ensuing year a Chicago physician, Dr. Moyer. This may be interpreted as showing at once its appreciation of that distinguished gentleman's personality and its recognition of the gain it had made by holding its meeting in Chicago. The physicians of that city are numerous and of great weight in the profession, and many of them joined the association during the meeting. These two things would hardly have happened if the association had not been pleased with Chicago or if Chicago had not liked its visitors; that they did happen is a matter on which the association may be congratulated.

NEURECTOMY AS A PREVENTIVE OF MASTURBATION.

The treatment of persistent masturbation, when it is a symptom of deep-seated nervous disease, has long been a source of despair to physicians. Many measures, moral, coercive, pharmaceutical, or mechanical, have been tried, commonly with varying and usually disappointing results. Dr. Campbell Clark and Mr. Henry E. Clark, however, report in the Lancet for September 23d a surgical measure undertaken not with a view to exercise mechanical restraint, but to eliminate sensation and therefore gratification. It was performed, with the necessary consent, of course, upon a middle-aged man who had been insane only about three years, and who had not shown any sign of early neuro-mental degeneracy. The operation, consisting of the resection of a portion of the afferent nerve of the reflex circuit, was performed as follows: After the usual aseptic precautions, a dressing of lint steeped in carbolic solution (one per cent.) was applied to the region of operation and was kept on for four hours before the operation. The incision was transverse and was made across the dorsal surface and about half an inch from the root of the penis. The skin here being elastic and flaccid, it can be drawn into a longitudinal fold, and this is easily transfixed transversely by a sharp, narrow-bladed knife without injury to the dorsal vein. The nerves, two in number, are not easy to identify or isolate, being intimately wrapped up in the loose superficial fascia. They must be sought for on the lateral margins of the dorsum of the penis, and they are in close relation to the dorsal arteries, generally to the outer side of these. Fortunately, the arteries are more closely attached to the capsule of the corpus cavernosum and they are not, therefore, liable to be injured. The nerves were raised by means of a blunt hook and about half an inch of each nerve was resected. The wound was closed by a continuous catgut suture and, after it had been made thoroughly dry by washing with ether, a layer of thin gauze was made to cover it by means of collodion. The healing process took ten days and the patient made a satisfactory recovery.
The result was entirely satisfactory. The habit has been discontinued for over a year, sensation being absent, and the beneficial effect upon the patient's mental condition has been marked, he being, say the authors, "no longer the degraded creature he was." No atrophy of the testicles ensued. Some mental depression followed the operation for a while, but disappeared in time. The man, however, is said to "admit that he is not so energetic as before the operation." It is clear that such an operation, entailing, as it does, all loss of sensation and power of erection, must be safeguarded against such an excess of surgical enthusiasm as once set in around the operation of chitoridectomy. Especially in the young must it be held in abeyance; for it is folly to affect to deny that numbers, if not the majority, of young boys have masturbated to some extent at some period of their lives, and yet have grown up into healthy, clean, and wholesome men—and to run the risk ofemasculating such an infanty. But among the insane and the incorrigibly vicious, the operation as described may with due safeguards find, perhaps, a legitimate place.

THE TREATMENT OF APPENDICULAR INFLAMMATION.

We seem to have made a pretty close approach to what may be called the "regulation" treatment of inflammation of the vermiform appendix and its consequences. Nevertheless, it is well to give heed to the opinions of all capable observers, even if not everything that they have to say is new or supported by novel arguments. Of such a character is an article by Tripiet and Paviot (Archives générales de médecine, July: Indépendance médicale, July 36th), who dwell primarily upon the peritonitic nature of the appendicular attack, a question with which we will not at present concern ourselves, but proceed at once to give the substance of their views as to the treatment. They accept the opinion that has seemed predominant in recent French discussions, to the effect that not only is surgical intervention indicated whenever there is the slightest sign of gravity, but gives the best results in all cases in which it is resorted to early. This exclusively surgical practice is not founded on the invariable gravity of the disease, for statistics prove that spontaneous recovery is frequent, but on the difficulty, if not the impossibility, in many cases of distinguishing when the trouble is grave or likely to become so.

When the patient has undergone one or more attacks and seems free from any indication of the least danger, feeling no pain and being able to resume his usual occupation, the question of surgical intervention is still in order. If deep palpation in the neighborhood of McBurney's point reveals the slightest induration, and if pressure in that locality gives rise to any special sensation, the peritonitic focus is not extinct, and there is always danger of fresh accidents. In such cases an operation is called for. Only when all signs of peritonitis have disappeared is reliance on non-operative treatment permissible. Among the features of such treatment, the authors give prominence to prolonged and absolute rest, extending far beyond the cessation of all symptoms, and in so insisting they are undoubtedly justified.

THE TOAD AS AN INTERMEDIARY HOST OF THE TYPHOID BACILLUS.

Dr. G. Law makes an ingenious suggestion in the Medical Standard for October, and one that is worthy of scientific investigation. He points out that toads and frogs spend the summer months ingesting flies and other insects. Flies, of course, swarm and breed around fecal matter. During the winter the toad hibernates, to reappear in the late spring. In view of these facts Dr. Law suggests that "a study of the intestinal contents of the common toad when he first comes out of hibernation in the early summer might reveal important facts in the life history of Eberth's bacillus." The author quotes a curious case in which, in June, 1899, there was an outbreak of typhoid in an outstanding farmhouse, there having been no cases of typhoid fever in the neighborhood, either city or country, since the preceding November. Three members, ranging from five to twenty years old, were first attacked simultaneously, and subsequently two others were attacked. There seemed to be no explainable source for the first cases. In August, however, a few days after the last case began, "portions of the skin and muscle of a toad were drawn from the tap at the kitchen sink." On these premises the author builds the following ingenious theory: In the preceding October many casuals were employed on the farm. One of these may have had ambulant typhoid and used the outdoor privy. From fecal matter to fly, and fly to toad passed the bacillus, remaining dormant until hibernation was over, when one or more toads found their way into the well and thus started the outbreak.

THE ANTIQUITY OF BUBONIC PLAGUE.

The antiquity of bubonic plague would appear to be shown by a writer in the Indian Medical Gazette for September, who quotes in the vernacular a passage from Susruta, part Nidāṇāthāna, which he translates as follows: "Deep, hard swellings appear in the arm-pit, giving rise to violent fever, like burning fire, and internal burning sensation. It kills the patient within seven, ten, or fifteen days. It is called Agnirohini. It is due to sannipata (deranged condition of all the three humors, bāta, pitta, and kapha), and is an incurable disease." On this the author comments as follows: "The question is, what disease do the Ayurvedic physicians refer to? It can not be that they meant by Agnirohini a mere local complaint of a trilling character,
though the chapter in which it is mentioned is khudra-roga (minor complaints). It is distinctly febrile, very much so, and of a deadly character. A definite duration also is given as a characteristic of the disease. Add contagiousness to it and it resembles modern bubonic plague. Can a disease formerly non-contagious become contagious by evolution and vixia versa by involution? The fact that contagiousness is not specifically mentioned does not seem to us sufficient to outweigh the other conditions, pointing, it would seem, clearly to bubonic plague.

THE WAR IN THE TRANSVAAL.

We have heard a great deal of the British army medical department during our war with South Africa. The probability at this time of writing that before this journal is issued England will be at war in the Transvaal will give us an opportunity of observing the medical arrangements and their practical value in something more approaching civilized warfare than was the Sudan campaign. We imagine, from the noted proficiency of the Boers in shooting, that much valuable material will be added to our knowledge of the effects of projectiles. But, however the system works, we feel sure that our British colleagues will personally acquit themselves creditably in their arduous duties.

PERMANGANATE OF POTASSIUM AS A DRESSING FOR BITES.

Dr. D. B. Das describes in the Indian Lancet the case of a woman, aged sixty years, who was said to have been bitten by a rabid dog. The wounds were very severe. "Almost all the soft structures of both the hands were wanting. Blood was flowing out in streams. Hand, arm, body, face, and scalp all had got the same fate." The treatment consisted of washing with a lotion of thoroughly hot Condy's fluid, and subsequent dressing with equal parts of iodoform and potassium permanganate. The healing was prompt and satisfactory, notwithstanding the lacerated condition of the wounds. Dr. Das has previously used the same treatment in dog bite with excellent results. He asserts that there is less sloughing than is customary under this treatment.

VACCINATION IN ENGLAND.

The antivaccinationists have scant reason to rejoice over their success in practically nullifying the compulsoriness of vaccination in England, so far, at any rate, as a suppression of the "loathsome" process is concerned, for we learn from the British Medical Journal for September 30th that in the half year ending June 30th the total public primary vaccinations were no fewer than 335,967 as compared with 278,588 in the corresponding half of last year. In other words, there has been an increase of vaccination to the extent of about 27.78 per cent. in spite of the "conscience clause." The number of conscientious objectors, therefore, can scarcely be so large as the antivaccination leagues would have us believe.

THE MOUTH AND CHIN OF WOMAN AS AN INDEX OF CHARACTER.

According to the Riforma medica for September 14th, Dr. Weingartner is of the opinion that a woman's character can be completely known from a study of her mouth and chin. A round chin, downy in the fissure, betrays little force of will, love of pleasure and frivolity, and is typical of a kind, affectionate, polite, good-hearted woman, but extravagant, whimsical, and capricious. When the chin is small and mobile, and slightly projecting, it is a sign of a strong will. Such a chin marks a woman of more imagination than heart, desirous of excelling, with a mixture of sentiment and practical sense, with jealousy added. The mouth small, with the lips moderately full, the upper lip slightly projecting, is distinctive of a cold heart, suspiciousness, but little sentiment, a calm and reflective temperment, pride, ambition, and egoism. A month of proper proportions he considers to denote the exact opposite. The Riforma medica suggests this subject as a new field for research. Will the lady doctors give us some points on the character of men from similar observations?

ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending October 7, 1899:

Marine-Hospital Service Health Reports.—The following cases of small-pox, yellow fever, cholera, and plague were reported to the surgeon-general during the week ending October 7, 1899:

Small-pox—United States.

- Chelsea, Mass. Sept. 23-30. 3 cases.
- Cincinnati, Ohio. Sept. 22-29. 1 case.
- Seattle, Wash. Sept. 16-23. 2 cases.

Small-pox—Foreign.

- Antwerp, Belgium. Sept. 9-16. 2 cases.
- Dusseldorf, Germany. Sept. 2-9. 1 case.
- Bombay, India. Aug. 29-Sept. 5. 1 case.
- Chihuahua, Mexico. Sept. 16-23. 2 cases.
- Mexico, Mexico. Sept. 8-17. 6 cases. Two deaths. One death.

The Medical Society of the County of Albany.—At the semiannual meeting, on Tuesday evening, the 10th inst., Dr. James W. Wiltsie read a paper on The Etiology and Treatment of Tuberculosis in Children.

The Buffalo Academy of Medicine.—At the last regular meeting of the Section in Medicine, on Tuesday evening, the 10th inst., Dr. Irving P. Lyon presented a paper on Malaria, which was discussed by Dr. Stockton, Dr. Clinton, and Dr. John D. Howland.

Changes of Address.—Dr. Hugh H. Hagan, to No. 30 West Forty-fifth Street, New York; Dr. Charles H. Lewis, to No. 47 West Fifty-eighth Street, New York; Dr. Albert J. Wittson, to No. 221 West One Hundred and Twenty-second Street, New York.

Army Intelligence.—Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from September 16 to October 7, 1899:

Alexander, James A., Acting Assistant Surgeon, United States Army, will proceed to Lands End, Port Royal, South Carolina, to relieve Howell, Evan P., Acting Assistant Surgeon, United States Army.

Bailey, Guy G., Acting Assistant Surgeon, United States Army, will proceed to Manila on the transport George W. Elder, instead of on the transport Sikhd.

Collins, Christopher C., First Lieutenant and Assistant Surgeon, United States Army, is assigned to Madison Barracks, New York, for duty.

Goodever, Guy M., Captain and Assistant Surgeon, United States Army, is assigned to duty at Pinar del Rio Barracks.

Hill, John S., Acting Assistant Surgeon, United States Army, will report to the commanding officer of the United States troops on the transport Centennial, for duty on that ship, relieving Kellog, P. S., Acting Assistant Surgeon, United States Army, who will at once report to the commanding officer of the United States troops on the transport Grant, for duty during the voyage of that vessel to the Philippine Islands.

Keever, Frank R., Captain and Assistant Surgeon, United States Army, now on duty in the Philippine Islands, is relieved from further station and duty at Fort Walla Walla, Washington.

Bailey, Guy G., Acting Assistant Surgeon, United States Army, will proceed to Manila on the transport Sikhd.

Balch, Lewis, Major and Surgeon, United States Volunteers, will proceed to the Philippine Islands on the transport Sheridan.

De Niedeman, William F., Major and Surgeon, United States Volunteers, will proceed to San Francisco for duty.

Gonzalez, Stephen M., Acting Assistant Surgeon, United States Army, will proceed by the next United States transport sailing from New York to San Juan, Porto Rico.

Koerner, Egon A., Lieutenant-Colonel and Deputy Surgeon-General, United States Army, will proceed in the order named to Fort Leavenworth, Kansas, Jefferson Barracks, Missouri, Fort Riley, Kansas, and Fort Crook, Nebraska, and make a thorough sanitary inspection of the volunteer regiments and their camps now at the above-named posts. Temporary camps that may be established for purposes of target practice will be included in the inspection.

Porter, Elias H., Acting Assistant Surgeon, United States Army, will proceed to Fort Crook, Nebraska, for duty, to accompany the Thirty-ninth Infantry to Minnesota.

Powell, Junius L., Major and Surgeon, United States Army, will act temporarily as medical inspector of camps on the Presidio reservation, relieving Wilson, William H., Captain and Assistant Surgeon, United States Army.

Tilton, Henry R., Lieutenant-Colonel and Deputy Surgeon-General, United States Army, will inspect the camp of the Forty-fifth Infantry, United States Volunteers, at Fort Snelling, Minnesota.

Ware, Isaac P., Captain and Assistant Surgeon, United States Army, having been found incapacitated for active service on account of disability, has been wholly retired, and his name will be henceforth omitted from the Army Register.

Wells, G. M., Captain and Assistant Surgeon, United States Army, is granted leave of absence for twenty days, with permission to visit the United States.

Naval Intelligence.—Official List of Changes in the Medical Corps of the United States Navy for the Three Weeks ending September 30, 1899:

Berrill, T. A., Surgeon. Detached from the Panther and ordered to the Monongahela.

Bohert, E. S., Passed Assistant Surgeon. Ordered to the New York, October 3d.

Crandall, R. P., Passed Assistant Surgeon. Detached from the Iowa and upon relief to proceed home to await orders.

Guest, M. S., Passed Assistant Surgeon. Detached from the Wabash and ordered to the Philadelphia Naval Hospital.

Killebrew, C. P., Passed Assistant Surgeon. Detached from the Philadelphia Naval Hospital and ordered to the Iowa.

Riggs, C. E., Passed Assistant Surgeon. Detached from the New York and ordered home to await orders.

Wright, B. L., Assistant Surgeon. Ordered to additional duty on the Monterey.

Blakeman, B. S., Passed Assistant Surgeon. Promoted to Passed Assistant Surgeon from May 27, 1899.
Crawford, C. A., Assistant Surgeon. Detached from the Massachusetts and ordered to the Eagle.

Drennan, M. C., Medical Inspector. Detached from the naval recruiting rendezvous, Philadelphia, and ordered to Washington for examination for retirement, and then home to await orders.

Grew, E. J., Assistant Surgeon. Detached from the New Orleans and ordered to the Massachusetts immediately.

Hancock, F. B., Assistant Surgeon. Detached from the Eagle and ordered home to await orders.

Marine-Hospital Service. — Official List of Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the United States Marine-Hospital Service for the Seven Days ending October 5, 1899:

Murray, R. D., Surgeon. To proceed to Miami, Florida, for special temporary duty.

Gardner, C. H., Passed Assistant Surgeon. Granted leave of absence for two days.

Corbett, G. M., Assistant Surgeon. To report to medical officer in command, Baltimore, for duty and assignment to quarters.

Fox, Carroll, Assistant Surgeon. Relieved from duty at Baltimore and directed to report to medical officer in command of the Reedy Island Quarantine Station for duty and assignment to quarters.

Primrose, R. S., Acting Assistant Surgeon. Granted leave of absence for six days.

Miller, Charles, Hospital Steward. Granted leave of absence for twenty-one days from October 8th.

Society Meetings for the Coming Week:

Monday, October 16th: New York Academy of Medicine (Section in Ophthalmology and Otology); New York County Medical Association; Hartford, Connecticut, Medical Society; Chicago Medical Society.

Tuesday, October 17th: New York Academy of Medicine (Section in General Medicine); Buffalo Academy of Medicine (Section in Pathology); Ogdensburg, New York, Medical Association; Syracuse, New York, Academy of Medicine; Medical Societies of the Counties of Kings, St. Lawrence (seemingly), and Westchester (White Plains), New York; Hunterdon, New Jersey, County Medical Society (Flemington); Baltimore Academy of Medicine.

Wednesday, October 18th: Medico-legal Society, New York; Northwestern Medical and Surgical Society of New York (private); New Jersey Academy of Medicine (Newark); Philadelphia County Medical Society.

Thursday, October 19th: New York Academy of Medicine; Brooklyn Surgical Society; New Bedford, Massachusetts, Society for Medical Improvement (private); Medical Society of City Hospital Alumni, St. Louis; Atlanta Society of Medicine.

Friday, October 20th: New York Academy of Medicine (Section in Orthopedic Surgery); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society; Chicago Gymnacological Society (annual).

Paregoric in Seasickness. — Poussié (Revue médicale, May 17th; Indépendance médicale, June 21st) speaks highly of his experience during many years’ service in the mercantile marine of paregoric in seasickness, which has succeeded better in his hands than any other of the ordinary measures. The author prescribes the tincture in doses of half a coffee spoonful in a little water. Attention is called to the difference between the French and English preparations, the latter of which is weaker, and consequently requires to be used in slightly larger dose.

Deaths.

Born.

Donehoo. — In Elliottboro, Pennsylvania, on Tuesday, September 26th, to Dr. and Mrs. R. S. Donehoo, a daughter.

Married.

Cherry — Dowdney. — In New York, on Wednesday, October 4th, Dr. William S. Cherry and Miss Maud Dowdney.

Haven — Winthrop. — In Greenwich, Connecticut, on Thursday, October 5th, Dr. Henry Cecil Haven, of Boston, and Mrs. Isabelle C. Winthrop.

Knowles — Rockwell. — In Flushing, Long Island, on Saturday, October 7th, Mr. William W. Knowles and Miss Susie May Rockwell, daughter of Dr. A. D. Rockwell, of New York.

Page — Ensign. — In Orange, New Jersey, on Tuesday, September 26th, Dr. Peirson Sterling Page, of Springfield, Massachusetts, and Miss May Wickes Ensign.

Paulding — McLovane. — In New York, on Thursday, July 6th, Dr. Edward Paulding and Miss Margaret McLovane.

Pell — Morris. — In New York, on Monday, October 9th, Mr. Francis Livingston Pell and Miss Ellen Van Buren Morris, daughter of Dr. Stuyvesant Fish Morris.

Robison — Galbraith. — In Buffalo, on Wednesday, October 4th, Dr. Joseph H. Robison, of Bradford, Pennsylvania, and Miss Lettie R. Galbraith.

Woodhull — Hewitt. — In Red Wing, Minnesota, Mr. James Clifford Woodhull and Miss Charlotte Althea Hewitt, daughter of Dr. Charles N. Hewitt.

Died.

Fairbrother. — In New York, on Thursday, September 28th, Letitia Fairbrother, wife of Dr. Charles M. Fairbrother.

Hanson. — In Donaldsonville, Louisiana, on Saturday, September 30th, Aline L. Hanson, wife of Dr. T. H. Hanson.

Jacob. — In New York, on Tuesday, October 3rd, Dr. Paul W. Jacob.

Knapp. — In Hackensack, New Jersey, on Sunday, October 1st, Agnes M. Knapp, wife of Dr. Louis P. Knapp.

Lowe. — In Brookline, Massachusetts, on Saturday, September 30th, Dr. Lewis G. Lowe, in the seventy-second year of his age.

Thomas. — In New York, on Thursday, September 28th, Dr. Francis A. Thomas, in the seventieth year of his age.

Wallace. — In Old Lyme, Connecticut, on Monday, October 24th, Dr. W. H. H. Wallace, in the forty-third year of his age.

Wayson. — In Baltimore, on Tuesday, September 26th, Dr. George W. Wayson, in the eightieth year of his age.
LETTERS TO THE EDITOR.—SPECIAL ARTICLES.

Oct. 14, 1899]

Letters to the Editor.

THE CLIMATE OF ASHEVILLE FOR MALARIAL DISEASE, TUBERCULOSIS, ETC.

Asheville, N. C., September 14, 1899.

To the Editor of the New York Medical Journal:

Sir: For four years Miss Pauline P., now aged ten, suffered from a most distressing kind of malarial poisoning. The plasmodia were repeatedly demonstrated. The red corpuscles greatly reduced—destroyed. She lived then in St. Louis. Her physician exhausted the drugs suitable in such conditions. Quinine, nitric acid, hydrochloric acid, arsenic, and numerous other drugs were administered faithfully only to secure temporary relief. Relapse would follow in regular periodicity. The dry climates of Texas and Colorado were tried, and there the disease at first developed violent fever and then subsided somewhat after weeks or months of sojourn to reappear on her returning to malarial localities. But at those great altitudes she suffered much more while ill than in low altitudes.

At last, on counsel of physicians in charge, she migrated to Asheville, North Carolina, where the altitude is medium and the air not so exceedingly dry as in the climates above mentioned. Here she was not under treatment three weeks ere all symptoms disappeared without that fever explosion just stated. She has grown from a thin, pale little girl, unable to attend school, to a robust, rosy, active student—all in eight months' time.

I have watched the progress of other similar cases which were as striking.

Nor is it only in malarial disease that this climate seems so beneficial. Tuberculous patients and dyspeptics seem to invariably improve, and many are the apparently healthy people one meets daily on the streets and among residents who came here five, ten, twelve, twenty years ago, given up by their physician and friends. Now some of them are in business here; others come once in a while to avoid the most disastrous seasons of the year at home.

The beauty of the conditions is that the altitude is a "golden mean," neither too high nor too dry, so that one may recover and return home to less favorable climates. On making researches I have found some unquestionable evidence of this fact, and many physicians of the East and North have grasped the importance of this truth.

Of course, climate does not cure every case, and indeed none should depend on climate alone, for each case needs to be put on its own merit and be directed and managed accordingly. Those who fail to receive benefit are chiefly those who "know it all"; buy medicines right and left, according to their notions; spend their time at the billiard table or the saloon; overdo in exercise, mountain climbing, etc. As Sir Hermann Weber, M. D., F. R. S., well says: "Climate by itself, without careful medical supervision, is generally insufficient. The patient's blind reliance on climate often leads to errors, to aggravation of the disease, and to death." This he said with reference to consumption, but it applies in other affections benefited by climatic influences. So thoroughly convinced am I of the value of the climate of Asheville, properly utilized, that I look for this locality to become the most popular natural sanitarium in the country, and have concluded to carry on my professional work and investigations here in the future, in the line of chronic affections. I trust to have a series of specific reports ready within the year.

Paul Paquin, M. D.

THE LAW IN ITS RELATIONS TO PHYSICIANS.

By Arthur N. Taylor, LL. B.

XL

CRIMINAL LIABILITY.

(Continued from page 532.)

Pregnancy not necessary for Commission of the Crime; Statutory Exceptions.—In harmony with the above decision, and probably based upon the same reason—viz., that the chief aim of the law is to protect the woman from injurious attempts to cause her to miscarry—is the rule that it is not essential that the woman shall, in fact, be pregnant when operated upon, in order to render the person attempting to produce her miscarriage criminally liable. This rule can not, of course, exist where the statute under which the attempted abortion is sought to be punished expressly provides that the woman shall be pregnant; such statutes sometimes provide that it shall be a crime to produce or attempt to produce an abortion upon a woman "pregnant with child." In such a case it is an essential part of the crime that the person upon whom the attempt has been made was in fact so pregnant, and if the prosecution fails in showing this condition to have existed the accused can not be convicted even though it is clearly shown that he has attempted to produce an abortion. Nor will it make any difference in the necessity of proving the pregnancy that a new law may have been enacted obviating this necessity by eliminating the words "pregnant with child," after the time of the alleged attempt to perform an abortion and before trial, it being a constitutional guarantee that no person shall be convicted of a criminal act upon less evidence or evidence inferior to that which would have been requisite to a conviction at the time the alleged criminal act was committed.

Vitality of Fetus not Essential to Commission of the Crime.—It has been contended that if the fetus had lost vitality at the time the act intended to cause a miscarriage was committed, this will relieve the defendant of criminal liability. Upon this question we have two cases nearly contemporaneous—one from the supreme court of Massachusetts, decided in 1858, and one from the supreme court of Vermont, decided in 1859, which at first blush appear to be in conflict. The Vermont case lays down the rule squarely that where a physician attempts, with unlawful intent, to produce an abortion, it is no defense that it may be subsequently discovered that the fetus had lost vitality previous to the operation or that the case was one in which it would have been necessary to destroy the fetus to save the mother. If the physician did not know this fact at the time of treat-

dering to her such medical services as her real needs required. Probably the physician's best safeguard against an attack of this sort is the exercise of discrimination in the choice of consultants, for if a consultation is secured with consultants whose professional integrity is irreproachable, no imputation of bad faith can be safely made, much less maintained.

The supreme court of Massachusetts, in a case before them some years ago,* expressed their approval of an instruction given to the jury in the trial court, wherein the legal duty of the physician in an emergency of the sort in contemplation was said to be at a much lower standard than that above fixed. Therein the trial judge said: "A physician may lawfully procure the miscarriage of a woman pregnant with child by any means applicable and reasonable for that purpose, directly or indirectly, if in so doing he acts in good faith for the preservation of the life or health of such pregnant woman. The justification of a physician thus acting must depend upon his exercising his best skill and judgment, and in the honest belief that the acts directly applied to produce a miscarriage, or applied to the treatment of a disease so as to involve a miscarriage as not unusual incident of such treatment, are necessary to save such pregnant woman from great peril to her life or health."

While the standard upon which this instruction is based is the one underlying nearly the whole law of civil and criminal liability, yet it can not be safely advised that the courts will in similar cases follow the opinion therein expressed. Moreover, should this opinion be followed, the question of fact to be determined by the jury of whether or not the physician did exercise "his best skill and judgment" and act "in the honest belief" that such operation was necessary, will be a perilous one which will be eliminated from all cases in which the physician observes the legal duties herein first laid down.

The necessity of destroying the child to save the mother's life, as contemplated by the statute, applies to those cases only where the death of the mother can reasonably be anticipated to result from natural causes unless the child is destroyed. For example, it is evidently not within the meaning of the statute that the physician's conduct in destroying the child is justified as necessary to save the mother's life when the only reason to anticipate the mother's death from a continuation of her condition of pregnancy is that she has threatened to commit suicide if she is not operated upon.† Nor is the consent of the mother to the operation, nor a desire to screen her from exposure and disgrace, any justification for the act.‡

Burden of Proving Existence or Non-existence of Necessity for Operating.—Whether it is necessary for the State to prove as an essential feature of the case of the prosecution that an abortion was not necessary to save the life of the mother, or whether, on the other hand, this fact will be presumed and the burden of proving that such operation was necessary to the mother's safety devolve upon the defendant, should he desire to maintain such a defense, is a question upon which the courts are divided.

The general rule of evidence regulating the burden of proof is that the burden or requirement of proving

---

† Hatchard vs. State, 79 Wis., 357.
‡ Com. vs. Wood, 77 Mass., 88; Com. vs. Snow, 116 Mass., 47.
any fact lies upon the party who substantially asserts the affirmative of the issue. This rule is, however, subject to a number of well-recognized exceptions, among which is the rule that when a statute, in creating or defining an offense, makes negative matter or a negative condition a material element of the offense described, then this negative condition must be proved by the party enforcing the operation of the statute. That the statutes of the several States prohibiting the production of abortion, as usually worded, come within this exception, seems evident; yet in apparent conflict with this rule, at least in the present case, is the rule that where facts are peculiarly within the knowledge of either party to a suit the burden is upon that party to prove them.

The supreme court of Oregon, in a well-considered opinion, denies the application of the last rule mentioned to this class of cases. The court, speaking through Justice Thayer, says: "The relative convenience of the parties to make the proof ought not, it seems to me, to be taken into consideration; but, in any event, no such rule should be applied to a criminal case, where the accused is presumed to be innocent, and the prosecution is required to prove him guilty beyond a reasonable doubt. . . . Proof that a physician, in his professional treatment of a woman pregnant with a child, has used means, with the intent thereby to destroy the child, and the death of the child was thereby produced, is not evidence that the treatment was not necessary to preserve the life of the mother; nor, if it produced the death of the mother, that it was not an honest effort on the part of the physician to preserve her life. The experience of mankind shows that cases have often arisen in which such treatment has necessarily been resorted to, and, in the absence of other proof, the law, in its benignity, would presume that it was performed in good faith, and for a legitimate purpose. The extent of proof to establish the negative averment in such a case would necessarily be limited by the circumstances. It could not, in the nature of things, be made positive, except as aided by the fact that the accused was able to refute it absolutely, if untrue, and had failed to attempt to do so."* The supreme court of Minnesota, in examining a question very nearly related to this one, indicated its disposition to hold the law as above laid down,† while the supreme court of Ohio very clearly expressed its opinion that it was incumbent upon the State to prove that the producing of the abortion was not "necessary to preserve the life of such mother." The ground, however, upon which this court arrived at this conclusion was that the facts showing whether or not it was necessary to perform the abortion to save the mother's life were not peculiarly within the knowledge of the defendant. Upon this point the court, speaking through Chief-Justice Day, said: "The circumstances attending the procurement of an abortion, tending to prove that it was unnecessary for the purpose of preserving the life of the mother, ordinarily can be shown quite as easily upon the part of the prosecution as it can be proved by the defendant that it was necessary for that purpose." The negative of the fact that the abortion was advised by two physicians, the court holds, for a like reason, is not necessary to be proved by the State. Here the fact that the physician obtained the advice of two physicians of the necessity of the operation, if indeed he did, is one which is peculiarly within his knowledge and one of which it might be impossible for the State to prove the negative.*

Upon the other hand, it is held in several well-considered cases that it is not incumbent upon the State to show that the operation is not necessary, but that this is a matter of defense peculiarly within the knowledge of the defendant, which he must prove if available.

The supreme court of New York lays down the rule unqualifiedly that it is not for the State to prove the absence of a necessity for performing the operation, but that this is a matter of defense which must be affirmatively proved by the defendant.† The same rule is adhered to in the State of Wisconsin.‡

*(To be continued.)

Gonorrhoeal Salpingitis.—Mr. J. W. Taylor, F. R. C. S. (British Gynaecological Journal, August), in a paper recently read before the British Gynaecological Society, submitted the following propositions which he was "disposed to maintain, and on which he invited the criticisms of his colleagues": 1. That a large number of women who are suffering from tubal disease have been at some time or another exposed to the infection of syphilis as well as of gonorrhoea. That these undoubtedly show marked improvement after a prolonged course of mercury and iodides, and in the course of this treatment, unless acute pyosalpinx intervenes (in which medicine is useless), it is the rule rather than the exception for all gross physical signs of disease to slowly and permanently disappear. 2. That many cases in which there is no history of syphilis, including cases in which there is an unmistakable history of gonorrhoea pure and simple as the sole cause and starting-point of tubal disease, do similarly improve and get permanently well under the same course of treatment, provided always that the disease stops short of acute pyosalpinx and its dangerous complications. 3. That acute pyosalpinx is peculiarly liable to occur in the first place on the left side of the body, and its special severity is probably due to secondary infection from the rectum. That cases of pyosalpinx, whenever possible, should be treated by free incision of the posterior vaginal fornix, by thorough exploration and emptying of all pus cavities from the pouch of Douglas, and by iodoform gauze drainage. That this is far preferable to the older operation of removal of the appendages, which is not only much more dangerous, but is peculiarly liable to be followed by facial fistula, an operation sequel sometimes worse than death itself. 4. That such cases of mixed infection and acute suppuration treated by operative evacuation of the pus, with or without removal of the appendages, do sometimes not only recover but remain permanently well without further treatment, the acuteness of the inflammation appearing to terminate the process of infection. In other cases, recovery is not so complete or relapses are met with, and these cases should be followed up by a course of specific treatment, the bene-

† State vs. McIntyre, 19 Minn., 92.
Frambusia or Yaws.—Seeing that this disease is more or less indigenous to some of our new possessions —viz., the West Indies and the Malay Peninsula (which is in communication with the Philippine Islands) — it may not be amiss here to reproduce the excellent summary of it which appears in a supplement to the Journal of Tropical Medicine for September. The Journal says:

"In different parts of the tropical world an exanthematous disease, contagious in character, ushered in by some fever accompanied by rheumatic pains, and marked by an eruption of tubercles, which become in time moist, fungoid masses, is known by several local names. The name frambusia has been bestowed upon the ailment in consequence of the supposed resemblance of the eruptive masses to a raspberry (frambesia = a raspberry). The French and Germans designate the disease as pian; in Ceylon it probably falls under the heading of parangi; the Fijians term it coko; it is probably also the purra of the Malays; and some even claim that the 'button scurvy,' which up to the year 1851 was not infrequent in Ireland, belonged to this category. These names imply a widely spread geographical distribution to the disease. It has been recognized in the West Indies, tropical Africa, Ceylon, Java, Fiji, and Samoa, and in the Malay Peninsula and Assam. In Fiji, in tropical Africa, and in the West Indies epidemics of the disease are frequent, and Dr. Daniells states that the Fijians inoculate their children against the disease.

"The incubation period is a lengthy one, but, owing to the mildness of the initial constitutional disturbance, its duration is indefinite. From two to ten weeks of incubation are assigned as the usual limits, but six months even are mentioned as a possible incubatory period. Inoculations have an incubation period of from twelve to twenty days. The premonitory symptoms are variable, but usually mild and fleeting; they may, however, occasionally be severe. An initial fever, at one time denied, is in the majority of instances attended by but a slight increase in temperature, but pains in the limbs and a general feeling of being 'out of sorts' are always present. The characteristic eruption does not appear at once, but changes in the skin gradually lead up to the typical raspberry-like masses from which the disease derives its name. First, furfuraceous patches appear on the skin of the trunk or limbs, or both; the patches may coalesce and give rise to a general furfuraceous desquamation. It frequently happens that this stage may be so slight as to be overlooked. Secondly, papules appear beneath the epidermis and, gradually increasing in bulk, push their way up to the surface. Thirdly, the papules now become of the nature of tubercles, consisting of elevated nodules with a yellow top about the size of a pin's head. The yellowness, however, is not due to pus, but to an aggregation of a cheesy material in the apex of the enlargement. At this stage many of the tubercles abort, but the majority rather suddenly increase in size, become fungous in character, pink in color, and accompanied by a foul-smelling secretion, of a glutinous consistence and a dirty yellow color. Fourthly, the yaw shrinks, a brown scab takes its place, or an ulcer may succeed, and a stain or cicatrix, according to the depth of the pitting, results.

"The face and neck is a favorite site of yaws, and around the mouth and nostrils the tubercles may assume the character of a row or fringe. Even the mucous membrane of the mouth may be affected immediately within the lips. On the trunk and limbs the eruption is more frequently discrete in character, but around the anus and on the genitals the tubercles may coalesce into groups, ridges, or ragged fringes. The sole of the foot may be attacked, and the bursting of the tumor through the thickened epidermis causes considerable pain and swelling. The finger and toe nails are liable to be involved, causing troublesome onychia.

"The duration of an attack of yaws varies; it may disappear within two months, but, on the other hand, recurring crops may continue the disease for twelve months; an average attack lasts three months.

"The prognosis is, in fairly healthy people, favorable; but in persons weakened by any constitutional complaint the joints are apt to become swollen, ulcerated, and stiffened; chronic ulcers may form, which may assume phagedenic characters; septicaemia may carry off the patient, or he may die of pure asthenia.

"The treatment of frambusia is both general and local. Good food, frequent bathing, and attendance to the sanitary environment of the patient are essential. The local application of disinfectants, either lotions, powders, or dressings, is all that is necessary; attempts at destruction of the individual growths are futile. Iodide of potassium or small mercurial doses, or both combined, seem to exercise a beneficial effect upon the eruption. Hygiene and not inoculation is the keynote of prophylactic treatment."

Kala-azar.—The British Medical Journal for July 29th, commenting on the report upon kala-azar, a full abstract of which appears in the Indian Medical Gazette for July, says that this is the third report which the Indian government has received on the subject. The first was by Major Giles, who came to the conclusion, as a result of his investigation, that the chief characteristics of the disease were anaemia and dropsy, and that the cause was the presence of large numbers of ankylostomes in the intestine. In this connection Major Giles worked out the life history of the intestinal parasite, and showed that mud rather than water was the chief medium for its propagation and spread. The next report was made by Captain Rogers, whose researches led him to disagree with the conclusions arrived at by Major Giles, and to consider kala-azar as essentially a malarial disease which had acquired infectious properties. With these two opposing and somewhat confusing opinions on record, the government of India employed Major Ross,
whose work on malaria rendered him peculiarly fitted therfor, to work out this problem. Unfortunately, the time at Major Ross's disposal extended over only six weeks, so that he was unable to enter into the subject in the thorough manner that it deserves. His observations have, however, been sufficient to lead him to concur with the views of Captain Rogers. He shows that kala-azar may be divided into three stages, the characteristics of which are: 1. Recurrent attacks of high fever with rapid enlargement of the spleen, and generally also of the liver, in the first stage. 2. Great tumefaction of the organs, with low fever, in the second stage. 3. Cachexia, with gradual decrease of the organs, disappearance of the fever, and frequently intercurrent attacks of pneumonia or dysentery, in the third stage. The first stage, Major Ross believes, is chiefly that of the parasitic invasion; the second stage, that of the secondary effects of the invasion; the third stage, that of the tertiary effects—namely, the result of the secondary effects. He was not able in the time at his disposal to assure himself regarding the species of the malarial parasite which causes kala-azar. Whatever species it may be due to, he conceives the disease to be a form of paludism in which the infection falls with a very heavy incidence on the spleen and the liver, especially the latter. He considers that the enlargement of these organs and the low fever are the chief cause of the exceptional mortality. As regards the power of communicability and epidemicity of kala-azar, he does not agree with Captain Rogers's view that this is due to an intensification of the virulence of the malarial parasite, but holds that it may be explained in the same way as the communicability of ordinary malarial fever. Recent researches have shown that malarial fever is communicable by the agency of insects, and Major Ross thinks that this is sufficient also for kala-azar. It must be confessed, says the Journal, that, although the report is a remarkably able one and carries the reader along from the first to the last page, yet the gaps are still so wide that it is a matter of regret that Major Ross was not able to spend a year instead of six weeks on this investigation. In this respect the conclusions are unsatisfactory, and were they not confirmatory of a longer investigation by Captain Rogers, there would be justification for the criticism that though the arguments from analogy are fascinating, yet there is not sufficient material to establish the view so ingeniously set forward.

The Influence of Humidity upon the Human Organism.—M. Lerachoff (Revue d'hygiène et de police sanitaire, August; Lyon médical, September 3d) has studied in conjunction with M. Rubner the influence of extreme degrees of relative humidity of the air at temperatures of from 59° F. to 84° F. upon the general condition, the pulse, the respiration, and the temperature of the body. To saturate the air with aqueous vapors it was passed through metal cylinders filled with layers of pumice stone moistened with water. To dry the air it was made to traverse cylinders filled with calcium chloride. The author used Pettenkofer's respiratory apparatus in his experiments. From his tests he finds that dry air is easily borne even at a temperature of 84° F. Its action is tonic; the pulse becomes full and hard, respiration is easy, and perspiration increases. Dry air acts probably still better upon those with pulmonary affections, for to the normal action of dry air upon the organism is in the these cases superadded its inhibitory effect upon micro-organisms. The rôle played by the climates of San Remo, the Riviera, and Davos Platz in diseases of the lungs is thus easily explained by the dryness of their atmospheres.

Moist air, he says, has exactly the opposite effect. At a temperature of 84° F., it becomes very disagreeable and painful, and provocative of thirst. The temperature as well as the pulse have a tendency to rise, and the latter becomes feebler and easily compressible. Ordinarily, the augmentation of the humidity of the air is accompanied by an increase of its contained carbonic acid; but the disagreeable sensations experienced in a confined atmosphere are, he says, due rather to its exaggerated humidity than to the carbonic acid, whose quantity, even in a vitiated atmosphere, is very slight. Dry air he finds never to cause disagreeable sensations, and if such are associated with artificial heating, they are due to the presence of dust in the air. These researches, says the Revue, thus supply a scientific basis for facts already established.

The Local Treatment of Puerperal Infection.—Dr. Arnold Lea (Medical Chronicle, August), in a paper on this subject in which he gives an analysis of forty-eight cases, arrives at the following conclusions: 1. A rise of temperature over 101.4° F. during the puerperium, not obviously accountable for by other causes, should lead to a thorough examination of the genital passages. 2. If no sufficient explanation is found in the condition of the perineum or vagina, a uterine douche should be at once given, with due precautions. 3. If within twenty-four hours the temperature has fallen definitely, no further exploration is required, but the douche may be repeated if the temperature again rises. 4. If at the end of twenty-four hours the temperature is higher, and the pulse rate has increased, the cavity of the uterus should be explored with the sterilized finger. 5. If the initial rise of temperature is great (103° F. or over), with or without a rigor, the uterus should be explored at once, without waiting twenty-four hours to observe the effect of a douche. This is more especially indicated if the uterus is bulky, showing delayed involution, since this points to putrefaction of retained products, or to septic endometritis. 6. If clots or placenta are discovered, they should be removed by the finger or curette, a douche given, and a gauge drain inserted for twenty-four hours. 7. In the great majority of cases it is wiser to thoroughly curette the uterus with the object of removing the whole of the decidua and retained products. 8. There is no evidence that curettage, if done with every precaution, favors the spread of infection. In a large proportion of cases the infection is rapidly checked. 9. In very virulent infection early curettage, with the object of sterilizing the uterine cavity, affords the best chance of a successful result. 10. If curettage entirely fails, it must be repeated or not, according to the local condition present. The prognosis, however, in the absence of a definite localization of the infective process, is bad. 11. In some cases, if curettage fails, and there is no evidence of general peritonitis or of infection of the blood stream, vaginal hysterectomy, if performed in good time, may be successful. 12. Anti-streptococceal serum should be given early and freely in cases of proved streptococceal infection. It is of little use in the advanced stages of the disease.

The Centenary of the Royal College of Surgeons of England is to be celebrated in due form next year. The charter of incorporation was dated March 22, 1800.
The Significance of Epistaxis as an Early Symptom of Softening of the Brain and the Relation of Both Diseases to Arteriosclerosis.—Karl Kompe (Archiv für Laryngologie, Band IX, Heft 2, 1899; Laryngoscope, September), after a history of five cases, gives his reasons for thinking that epistaxis may be a symptom of the earlier stages of arteriosclerosis, and hence a forerunner of cerebral softening (encephalomalacia). It is established that selerotic changes are very apt to be set up in the carotids, especially the internal, as early as anywhere in the arterial system. These changes most readily pass along into the ramifications of the carotids. The ethmoidal artery, a branch of the ophthalmic, being thus derived from the internal carotid, supplies the upper and anterior nasal structures; while the sphenopalatine, a branch of the internal maxillary, and therefore a derivative of the external carotid, supplies the posterior portion. These vessels being among the first to become weakened may easily give rise to severe and frequent epistaxis. The intima becoming first affected, the blood seems to lose its coagulability, and in addition to this the elasticity and retractile power of the arterial coats being lost, there is no good reason why a hemorrhage should not continue almost to exhaustion. As a matter of fact, plugging the nases is often necessary. All practitioners, and especially laryngologists and ophthalmologists who are most frequently called to these cases, are urged to make a careful examination of the arterial system. This is of special importance, as treatment in the early stages does seem to accomplish some good, while later on it is of no avail.

Early Diagnosis in Pulmonary Tuberculosis.—Dr. S. G. Bonney (Medical News, September 30th), in a paper read at the meeting of the American Climatological Association, would especially condemn: 1. Delay in instituting any physical examination whatever until long after the development of pronounced constitutional and pulmonary impairment. 2. Failure to examine upon the bare skin, the presence of clothing effectually preventing any approach to accurate results. 3. Neglect to examine the entire chest, the bases, intercostal spaces, and axillary regions being frequently overlooked. He would deplore particularly the existence of: 1. Erroneous conceptions concerning the significance of the absence of percussion dulness at the apices, an active process often being capable of recognition by auscultation considerably before the evidences of consolidation are apparent. 2. The non-recognition, in the absence of rales, of the various modifications in disease of the normal respiratory sounds. 3. Inaccurate interpretation of localized diminished intensity of auscultatory sounds, elevation of pitch, harshness of quality and prolongation of expiration. He would severely criticize: 1. Failure to utilize cough preceding forced inspiration in eliciting the presence of slight moisture in the finer tubes. 2. The non-appreciation of the almost pathognomonic significance of a circumscribed bronchiolitis, even in the absence of dulness or other auscultatory signs.

Evolution of Lines of Sight.—Dr. Chalmers Prentice (Lancet, June 17th; Medical Review of Reviews, August) gives some interesting observations about the evolution of the lines of sight in binocular vision. He has noticed that herbivorous animals generally have divergent eyes, and can not look at an object with both eyes at the same time. In many birds the eyes are so situated as to look nearly in opposite directions. Such birds and beasts present the side of the head to an object to get the best view of it. Carnivorous animals have not nearly so divergent eyes as are found among the herbivora, and binocular vision is usually possible for them, but their eyes have a constant tendency to diverge, and are kept in visual alignment only by tonic contraction of the internal rectus muscles. Dr. Prentice has observed a slight, quick converging movement in the eyes of lions and tigers as they lay languidly closing and opening their eyes. After death animals present considerable divergence of both eyes.

Dr. Prentice found by testing the eyes of a thousand North American Indians with a prism, base down, to create a vertical diplopia, that in them, as well as in eight hundred uncivilized African negroes similarly tested, there is a general tendency of the eyes to diverge. In the entire eighteen hundred aboriginals, three cases only of convergence were met with. Thinking that the eyes might show the true anatomical condition after death in civilized man, the doctor has made a record of over three thousand cases, and has discovered that the eyes turned outward almost without exception in twenty-four to forty-eight hours after death. He has not found a single case where the eyes of the dead remained perfectly straight. In seventeen cases he has examined the same persons before and after death, in all of which having normal vision and perfect alignment of the optic axis during life, there was yet divergence after life had ceased.

From the above facts, the doctor thinks that even in civilized man there is a tendency to diverge, which is overcome and, in cases of convergent strabismus, turned into a functional convergence by a fixed, tonic spasm or innervation of the internal rectus muscles. That this functional convergence is not due to any anatomical shortness of the internal muscles is shown by the fact that the eyes of the blind invariably diverge to some degree. The doctor concludes that the eyes of civilized man are in a state of evolution as yet incomplete, requiring nerve energy to bring about normal binocular vision. The necessity for the use of the eyes for near objects in the various pursuits of civilization make functional convergence and accommodation still more of a strain on the innervation of the ocular muscles than is requisite for binocular distant vision. The partial relaxation possible in sending patients away for "change of air" may be a factor of relief in nervous persons, substituting open country for city blocks and distant vision for close accommodation. "If the evolution of the optic axes now goes on under civilization were complete, the nerve energy now required to maintain binocular vision could be utilized in performing other functions more perfectly, thus adding comfort and years to life. How much this strain is, or how much life is shortened and our peace and happiness disturbed by it, it is impossible to calculate; but it must be great, from the fact that the nerve centres of vision are so extensive; in fact, they are many times greater in area than those which furnish energy for our legs, and the legs may use more than a million foot pounds of energy in a day."

Mosquitoes in Relation to Malaria.—Dr. Ian Macdonald, assistant medical officer to the Rio Tinto Company, Spain (British Medical Journal, September 16th), has instituted observations with reference to the presence or absence of mosquitoes in certain localities.
The district, as a whole, over which his observations extend embraces an area of sixty miles, reaching from the southern part of the Spanish Sierra to the Atlantic. He has examined, in all, twelve districts; of these, nine have endemic malaria; the remaining three may be considered free from fever. Isolated cases do occur in two of them, but the author has always been able to trace the infection to a night or more passed in the fever zone beyond them. The remaining one on the sea coast is quite free from malaria.

The following shows the mosquitoes he has identified up to the present, and their distribution in the different localities:

Three Healthy Districts—Culex elegans, Culex phyllophagus, Culex pipiens, Culex spathipalpis, from large and found as adults. Culex penicillaris, adult specimen only; seacoast (pines).

Nine Malarial Localities.—The first four already mentioned; with also Anopheles claviger in all nine, Anopheles pictus in three, and Anopheles bifurcatus in one (one adult).

Most of the malarial villages are situated on the face of a hill, with small ravines or partially dried up streams at its foot. In small pools in these ravines he has always found anopheles larvae without difficulty, and in one district notoriously malarial the larvae of Anopheles pictus were present in great abundance. It will be seen that here, as in Italy, up to the present Anopheles claviger is the predominating anopheles.

During four years’ residence in a fever-stricken locality, the only Englishman who has avoided fever has invariably slept under curtains. Further, he has always made it a custom, in order to avoid being bitten when sitting outside his house in the evening, to cover his feet with towels, protecting his hands with gloves, and his neck with a muffler. His servant has suffered severely from fever. The only mosquito present in his house is Anopheles claviger. They are found in numbers in the rooms of the house and adjoining shed.

The healthiest area is on the coast, where the company has its sanatorium on a sandy shore. Malaria does not occur there. Mosquitoes exist, but are hardly noticeable. The author has found Culex penicillaris biting sometimes at night, and has obtained here Culex spathipalpis from larve. Six miles farther along the coast he visited a fishing colony of a hundred people, all of whom were suffering from fever at the time of his visit, for those who were not actually ill said they awaited their attack next day. Three deaths had occurred among them in a week from pernicious attacks.

The only difference between those two coast areas consisted in the latter having behind it a small lagoon, some stagnant pools, and disused surface wells. In all those places the author found anopheles larvae. The people said they were bitten furiously at night by a large mosquito. Their “patron” alone slept under curtains and had not had fever. Adult specimens sent from their huts were A. claviger and one A. bifurcatus.

Can it be said, asks the author, that these facts are only coincidences? That might be possible, but looked at in connection with recent researches into the life cycle of the parasite in anopheles, it will be probably considered that they have a direct bearing on the all-important problem of malarial infection.

The Treatment of Intestinal Catarrh.—Dr. G. C. H. Mcier (Boston Medical and Surgical Journal, September 21st) epitomizes his experience in the following conclusions: 1. That in all diarrhoeal affections of recent duration it is of the utmost importance to free the intestinal canal of all irritating material, preferably by the use of small doses of calomel. 2. After this has been accomplished, it is usually necessary to restore the toxicity of the relaxed intestinal mucous membrane and to check the discharges by the use of astringents. In diarrhoeal affections of some days' duration, especially in children, it may be advisable to resort to the use of astringents at once in order to prevent exhaustion and collapse from the profluse and frequent evacuations. 3. The best form in which to administer an intestinal astringent is one by which the astringent principle is slowly liberated in the intestinal canal so as to avoid any irritant effect upon the stomach, and also to subject the lower intestinal tract to the influence of the remedy. 4. Tannopine represents an efficient and reliable intestinal astringent, which, owing to its innocuousness, is well tolerated by the smallest children, and which, while an active astringent, is entirely free from irritating effects upon the intestinal canal.

Chamber Disinfection after Death from Phthisis.—Dr. Edward O. Otis (Boston Medical and Surgical Journal, September 21st) says that the importance of disinfection or renovation after a case of phthisis is in his experience not generally appreciated. No tenement, apartment, or room should be again occupied or let until satisfactory evidence of thorough disinfection or renovation has been furnished. A case narrated to him by a physician of Boston will illustrate the importance of this. The daughter of the landlady of a well-to-do boarding house died of consumption. Some time afterward a young woman from the West took up her residence in the boarding house and occupied the daughter’s room. In the course of time she exhibited evidences of tuberculosis, and her physician, suspecting the source of infection, had her removed. Such experiences were probably familiar to many. According to the author’s knowledge the disinfection of premises which have been occupied by consumptive patients and vacated, either by death or removal, before they can be occupied, is compulsory only in New York city, Italy, and Spain.

The Ocular Causes of Headache.—Dr. S. D. Risley (Journal of the American Medical Association, September 23d) thus concludes a paper read before the Section on Neurology of the American Medical Association at Columbus: The following conclusions may be regarded as established by clinical experience: 1. Abnormalities of the ocular apparatus are in a large group of patients the sole and sufficient cause of headache. 2. These abnormalities of vision may be the unsuspected cause, and therefore the absence of symptoms obviously referable to the eyes does not exclude them as an aetiologic factor in headache, insomnia, vertigo, petit chorea in children, and certain stomach derangements. 3. The recent or sudden development of symptoms, after attacks of severe illness, as typhoid fever, the exanthemata, etc., or in association with more or less acute exacerbations of some general dysrasia, is not sufficient evidence against ocular participation in causing the symptoms. 4. The participation of the eyes as an aetiologic factor in headache can be positively excluded only in the absence of ocular disease or after the most painstaking correction of any existing error of refraction or abnormality of binocular balance. 5. For the relief of
reflex symptoms accurate corrections are essential, and these can be secured only by the more or less prolonged use of a strong cycloplegic. 6. Immediate relief by these corrections in a large group of patients is not to be expected, since the pain is frequently due to associated pathological conditions of the fundus oculi, which require time for cure.

Plague.—Dr. W. J. Simpson (British Medical Journal, September 16th) says that two features are specially characteristic of plague: 1. The slow, irregular manner in which it acquires a hold over the locality into which it is imported and which may subsequently become the scene of an epidemic. 2. The obscure nature of the earlier cases. The first is apt to cause procrastination in vigorous measures; the second, loss of time through disputed diagnoses. There are two forms which often escape attention, the pneumonic and the ambulant. The pneumonic form lacks the pain, tenderness, and swelling of the glands, which are the most prominent external signs of bubonic plague, and is very likely to be mistaken for bronchitis, broncho-pneumonia, or pneumonia. There are the usual symptoms of febrile infectious diseases, premonitory and otherwise, with cough and watery sputum tinged with blood, which will be found to be almost a pure culture of plague bacilli. These cases rapidly become worse, and commonly end fatally. These are also the most infectious.

On the least suspicion, therefore, that plague may be present in a locality, the sputum of all pneumonic cases should be examined by spreading on a cover glass, drying, fixing, and staining with gentian violet, methylene blue, carbol fuchsin, or any ordinary aniline dye. A one-twelfth oil-immersion lens will show, if present, the characteristic coco-bacilli or diplobacteria, more stained at the ends than in the centre. If they are found, then it is imperative that the sputum be sent for confirmatory cultivation in a laboratory.

The ambulant form is particularly dangerous, being very mild, non-fatal, apparently sporadic, and commonly mistaken for some other disease—e.g., mumps, syphilis, malarial disease, scrofulous glandular affections, etc. These mild cases occur in almost every epidemic, and, owing to their escaping notice at first, disseminate infection before suspicion is aroused. There is some fever, pain, tenderness, and enlargement of glands, weakness, a tongue with creamy white fur in the centre and angry red at the edges and tip, the eyes are congested, and the speech somewhat thick.

The bubonic plague is, of course, always accompanied by buboes appearing at the commencement of the illness in the groin, axillae, and neck. There are certain symptoms common to all severe forms of plague. The countenance generally portrays in the early stages anxiety and distress, later resignation and apathy; the eyes are red and congested, and the patient has the appearance of being under the influence of a hypnotic, and yet unable to sleep, the eyes remaining wide open. Unless delirious, when the face is flushed and the physiognomy wild, the expression in advanced cases is apathetic or vacant, masking the approaching dissolution. The speech is peculiarly hesitating and broken, being more or less staccato in character, each syllable being pronounced by itself in a thick and husky tone like that of a drunken man, or only half the sentence may be spoken, the rest being forgotten. The tongue is early coated with a creamy white fur, except the tip and edges, which are clean and red; later it is dry, covered with a yellowish or whitish-brown fur, the tip and edges remaining red and irritable.

The characteristic physiognomy, speech, and tongue, with the presence of a bubo, are unmistakable signs of plague. The general symptoms of a typical case are shivering, high fever, nausea, vomiting, intense general or frontal headache, painful and tender bubo, staggering gait, suffused and congested eyes, anxious expression, coated tongue except on tip and edges, restlessness, with uncontrollable desire to wander aimlessly to some distant locality, dyspnea, increasing disturbance of the nervous and circulatory systems manifesting itself in high and noisy delirium or coma, and in gradual or sudden failure of the heart’s action. The pulse, which is quite soft and easily compressible at the onset, becomes intermittent and dioretic and often difficult to count, and there is a tendency to collapse, the patient’s extremities becoming cold and clammy. After the sixth or seventh day the patient’s chances of recovery are much increased, and the temperature usually reaches the normal about the tenth day.

The Role of Insects, Arachnids, and Myriapods in the Spread of Diseases due to Parasites.—Dr. George H. F. Nuttall (Journal of Tropical Medicine, August), in a paper read before the British Medical Association, subdivides his subject as follows: a. The Role of Insects, etc., in the Spread of Bacterial Diseases.—1. Passive rôle. The domestic fly and allied species are chiefly to blame in this respect. Ineptable of “biting,” they may from the nature of the food they seek carry pathogenic bacteria in their bodies or within their alimentary canal and deposit them on lesions of skin or mucous membrane, or on food.

It is possible, however, and in many cases scientifically proved, that anthrax, plague, cholera, typhoid fever, frambesia, and Egyptian and “Florida” ophthalmia are so diffused.

2. Active rôle. Blood-sucking flies may play a part in propagating bacterial disease. Clinical writers report that cases of anthrax, septicaemia, pneumonia, and erysipelas arise in certain instances from bites of flies; but experimental evidence is all against this statement. Experiments made by the writer on animals with plague, anthrax, mouse septicemia, and chicken cholera all gave negative results.

b. The Role of Insects, etc., in the Spread of Diseases due to Animal Parasites.—Insects, etc., while serving as intermediary hosts, may play: 1st, a passive rôle, when they are devouring by a host of the parasites they contain: 2d, an active rôle when, as in the case of the tsetse in Texas fever, and various mosquitoes in malarious affections of man and animals, they inoculate into a host by means of their proboscis: 3d, if in filarial diseases an intermediary position is played by the mosquito, as it infests itself by sucking the blood of the definitive host.

Insects, etc., without serving as intermediary hosts, may play: 1st, a passive rôle, when they transport eggs of animal parasites and deposit them in food—e.g., eggs of Tunga solium, Trichophalus, Asciris lumbricoides; 2d, an active rôle, by carrying the diseased animal from one animal to another and inoculating the parasite—e.g., Tsetse fly.

Abdominal Suture after Laparotomy.—Dr. A. T. McCormack (American Practitioner and News, August 1st), in a paper read before the Kentucky State Medi-
cal Society, says: "To summarize, I would say that the most efficient method of repair of the abdominal incision would consist of the following distinct steps: 1. A continuous peritoneal suture of fine catgut. 2. An interrupted suture of chromicized catgut for the fascia with four sutures to the inch. 3. A running suture of catgut for the subcutaneous fat. 4. A subcuticular subcutaneous stitch of catgut for the skin."

Proceedings of Societies.

AMERICAN LARYNGOLOGICAL ASSOCIATION.

Twenty-first Annual Congress, held in Chicago, Monday, Tuesday, Wednesday, May 22, 23, and 24, 1889.

The President, Dr. William E. Casselberry, of Chicago, in the Chair.

(Continued from page 500.)

Acute Suppurative Processes in the Faucial Tonsil.

—This was the title of a paper by Dr. J. L. Goodale. (See page 509.)

Tonsillar and Peritonsillar Abscess.—Dr. George A. Leland read a paper with this title. (See page 512.)

Septic Thrombophlebitis as a Complication of Peritonsillar Abscess, with a Report of Two Cases.—Dr. M. R. Ward presented a paper on this subject. (See page 546.)

A Report of Cases of Peritonsillar Abscess associated with Diphtheria.—This was the title of a paper read by Dr. Thomas Hubbard. (See page 549.)

Dr. Cobb, of Boston: I will not take up the time of the society in reading the paper which these photographs illustrate, but will give a brief résumé of it, and then show the photographs. The object of the paper is to call attention to a space lying just outside the fascia on which the tonsil rests as a possible seat of peritonsillar abscess. This space is called by anatomists the pharyngo-maxillary space, and was first brought into clinical prominence by Zuckerkandl in an essay on the relation of the great vessels to the tonsil. Chiaria was, I believe, the first to attribute the location of peritonsillar abscess to this space. My attention was called to the study of the location of the peritonsillar abscess by the immediate closure of the punctures, which often occurred in attempting to relieve the condition. It was noticed that punctures, even when successful in obtaining a free flow of pus, often failed to evacuate the abscess, which only reformed to rupture elsewhere. The existence of a deep location for the pus covered by muscles and fascia running at an angle to each other, so as to close any aperture made by transfixing two or more muscles at a time, would explain this. The depth at which the pus must often be sought strengthens this view, as does the infiltration of the pus into the region of the great vessels, as reported by Dr. Hubbard. To ascertain the direction of the infiltration of the pus if contained in the pharyngo-maxillary fossa, hot wax was injected into the fossa through the tonsil on the cadaver, and after allowing time for the injection to cool and harden, sections were made through the head at about the level of the palate. These sections were then photographed, and they show the wax penetrating the soft palate and the space both above and below the tonsil. This photograph from Testut's Anatomy shows the normal appearance of the space, while the others give the appearance of the space when filled with wax. It will be observed that the great vessels are situated in the rear of the space, which is divided into two portions by the styloglossus and stylopharyngeus muscles. It is this partition which usually protects the great vessels from infiltration in peritonsillar cases. Dr. Hubbard's paper has shown us that it is not always a good protection.

Dr. Swain, of New Haven: I have had the pleasure of looking over the pictures of Dr. Cobb's and think they are excellent. They impress upon us the points he makes. We see by the photographs that have been passed around what a large space is easily formed by the introduction of wax; consequently, it is easy to assume that this space would readily admit the index finger; and the proposition Dr. Leland makes, of introducing the finger in the manner described by him certainly shows a radical method for breaking up the wall which forms the anterior and inner surfaces of the triangular space, thus aiding in the complete evacuation and cleansing of the abscess. I can readily see that if the operation described by Dr. Leland is done under an anesthetic, nothing more thorough and successful could be undertaken in the way of opening up these peritonsillar abscesses. I have recently had four or five cases come under my care in which the ordinary methods were not very successful, at least as regards locating the abscess cavity.

Dr. T. A. de Bloom, of Boston: I can bear witness to the thoroughness with which Dr. Leland does this operation, but I must say that it takes considerable boldness to go thoroughly through the tonsil in this way. There is always some doubt in the patient's mind as to what has been done. He is uncertain in his mind whether it is the finger or the whole arm that is inside of his mouth. (Laughter.) I remember assisting Dr. Leland in one case where the lady said Dr. Leland got his finger into my mouth and passed it down until it reached almost to my collar bone. This woman had a recurrent tonsillar abscess, and these abscesses occurred for many years until this most thorough operation. I am glad to bear witness to the fact that peritonsillar abscess never recurs after it has been done. I do not think then that there is any part of the tonsil left.

Dr. James E. Newcomb, of New York: Speaking of the clinical side in connection with Dr. Hubbard's paper, it recalls a case which, I presume, many of you have seen reported in the last number of Fraenkel's Archiv by Sendziak, of Warsaw, in which an attack of diphtheria was complicated by a succession of tonsillar and peritonsillar abscesses. One of the faunal tonsils had suppurating tissue around it, then the other; next, the nasopharyngeal tonsil underwent the same process, also the lingual tonsil, and finally the antrum of Highmore became completely inflamed. The point of interest to me was the spontaneous opening of the abscess in front of the lingual tonsil, attended by very profuse hemorrhage. That seems to be a very unusual complication in cases of this kind.

Dr. Swain, of New Haven: I wish to refer to the excellent work of Dr. Goodale in connection with the finer pathology of this subject. I am sure we were all very much interested in his paper; yet it is a difficult one to discuss adequately with impromptu remarks, and I wish I might do greater justice to it. I have frequent-
ly wished that, as we follow out our cases clinically, we might be able to say what cases were going to be severe and what cases were going to be comparatively mild. The book, however, is written in a style that makes it easy for the reader to follow the author's thoughts. It is a valuable contribution to the field of medicine and should be a welcome addition to any library.

The description of the book's contents is as follows:

The author informs us in a preface note that the volume is "nothing but a compilation"; and in that it quotes the work in sermon diagnosis and the conclusions of all who have recorded them, it certainly is such. As one reads, however, he is able to see how small a value such a compilation would have, were it not presented by one who not only thoroughly understood his subject, but had also that most excellent quality of being able to make others understand it. The value of the book is, therefore, not to be accounted for by mere compilation, and the work deserves more credit than its author would accord it.

We are introduced in the opening chapter to the phenomenon of agglutination, a term which it is unlikely needs definition. In the second chapter the technique of testing is described, and in the three that follow, the variations in the phenomenon as well as an inquiry into its nature. The five succeeding chapters concern the phenomenon of agglutination or clumping as it occurs in the Widal reaction. These chapters are the path of the work, and are as detailed and as exhaustive as the subject permits, the eighth chapter containing brief clinical histories which show the value of the test. The book concludes with a chapter dealing with the agglutination obtainable with the micro-organisms of other diseases when subjected to the action each of its appropriate serum. This field is indeed a vast one, but enough has been done in it to show how much diagnostic promise it contains. The book is both enjoyable and instructive.

---

The design and scope of this useful little volume are well expressed in its preface, from which we quote: "So rapidly do the advances in the various branches of medical science multiply, that one finds it an almost impossible task to keep abreast of the times without the aid of what might be called concentrated literature. In current publications many terms and neologisms are employed long before they find their way into text-books, encyclopedias, and dictionaries. For these reasons the authors have been led to compile an alphabetically arranged volume, giving so far as possible the
meaning of new terms and value of the new discoveries in the realms of practical medicine. The book includes the more recent and novel names of diseases, tests, methods, drugs, therapeutic and surgical suggestions, etc. It would have been impossible and unwise in a work of this kind to attempt even an enumeration of all the remedies recently introduced. In other branches as well, omissions have occurred, since to incorporate all the novelties of medicine, even for a single year, would call for a volume whose size would defeat the ends of condensation and portability.” For the greater part the selection had been well made, though among the inclusions are a few whose importance is of no great magnitude. The volume is characterized by brevity, but at the same time by clearness, and can scarcely fail to be of service.

The fifteenth American edition of Kirk’s Handbook of Physiology is marked by a number of minor changes which progress has demanded. In a few instances the changes have been of some importance, notably as concerns the ductless glands and muscle-nervous action. Apart from these, however, the book has the same features that have made its previous editions so deservedly esteemed.

Books, etc., received.

Miscellany.

The Medical Laws of Various Countries.—Dr. Julius Schwabhe, the editor of the Deutsche medicinische Wochenschrift, has compiled a most useful work, entitled Bestimmungen über die Zulassung zur ärztlichen Praxis in Auslande, giving the substance of the laws and regulations governing the practice of medicine in ninety-eight different communities representing practically the whole of America, Europe, Asia, Africa, and Australia. These communities he classifies as follows: 1. No special Laws.—China and Japan. 2. The requirement of a diploma or certificate authorizing the holder to practise in his own community.—Many States in the United States and some States in Africa. 3. The passing of a state examination.—Some States in the United States, Austria, and Turkey. 4. The passing of a state examination, with some concessions as to preliminary examinations.—Argentina, Denmark, France, the Netherlands, Spain, and Sweden. 5. Regular courses in the community’s own schools.—Belgium, Greece, Italy, and Portugal. 6. The same, with evidence of preliminary education.—Germany, Russia, and Switzerland. 7. Denial to all foreigners of the right to practise.—Luxembourg and Servia.

The Mississippi Valley Medical Association.—At the annual meeting held in Chicago last week officers for the ensuing year were elected as follows: President, Dr. Harold N. Moyer, of Chicago; vice-presidents, Dr. A. H. Cordier, of Kansas City, and Dr. S. P. Collings, of
Hot Springs, Arkansas; secretary, Dr. Henry E. Tuley, of Louisville; treasurer, Dr. Dudley S. Reynolds, of Louisville.

The Question of the Indication of Doses in the Pharmacopoeia.—At the recent annual meeting of the American Pharmaceutical Association, held in Put-in Bay, Ohio, Mr. Harry B. Mason, associate editor of the Bulletin of Pharmacy, read a paper before the Section in Education and Legislation, in which he said that there were many good reasons why minimum and maximum doses should be incorporated in the next Pharmacopoeia, and no good reason, he believed, why they should not. That their presence would undoubtedly increase the popularity of the book was reason enough in itself for their introduction. During the six years which had elapsed since the publication of the present revision a feeling had constantly been growing that the book should be so changed in character, or so broadened in scope, that it would spring into more general use among pharmacists and physicians. The Pharmacopoeia was a book which prescribed standards for the character, quality, strength, and comparative purity of medicines. It had been created by the professions of pharmacy and medicine, and had the authority and the influence which only entire representation could give. The government had accepted it as the national standard; manufacturing pharmacists made their products conform to its requirements; text-books and reference books in materia medica and pharmacy and pure-food and drug laws were based upon it; and judges were guided by it in making their decisions. It should surely be in the hands of every pharmacist and every physician in the country, but hardly one pharmacist in ten or one physician in a hundred had it in his library.

The introduction of doses, among other changes, would do much to increase the usefulness of the book and would therefore materially increase its popularity. There was little in the present Pharmacopoeia to interest the average physician. He cared nothing for descriptions, tests, and processes of manufacture. He wanted information along medical lines, and he would not buy or consult a book which failed to give him this information. If he was in doubt about the dose of some toxic remedy, and, knowing that the Pharmacopoeia was the recognized book of standards, turned to it with trust only to find it silent, he would discard the book as useless to him. It was this very lack of usefulness to the physician, with respect to doses and other things pertinent to his needs, which had prevented the Pharmacopoeia from being popular with medical men. The notion had gone abroad that the book was a pharmacist's book and that it had no value for the physician, and the consequence was that physicians were deplorably ignorant of its contents.

This ought not to be. The Pharmacopoeia should not be unknown to the great majority of physicians. Just to the extent that it was unknown and unread its very purpose was defeated. From a selfish point of view there were reasons of the most vital character why pharmacists could not afford to allow such a condition of things. The one great reason why the vast horde of proprietary medicines of every kind had been taken up with such acclaim by physicians was that they were ignorant concerning the Pharmacopoeia and its authoritative character. A knowledge of the Pharmacopoeia spread among physicians would do much to restore prescribing to official medicines, and thus restore pharmacy to the pharmacist. Moreover, a greater use of the Pharmacopoeia, which was the joint work of both pharmacists and physicians, would go far toward bringing the professions together, to the profit and pleasure of both and to the enhancement of medical science.

But the introduction of doses into the Pharmacopoeia would not only increase the use of the book among physicians; it would also increase its use among pharmacists, which was quite as necessary and desirable. The Pharmacopoeia was essentially the guide-book of the pharmacist, and, yet, unfortunately, it was too seldom found in his library. His excuse was that it contained nothing but what was in the dispensary. This was not true, and as an excuse it was certainly not sufficient; but the pharmacist would nevertheless continue to slight the Pharmacopoeia and to give this excuse unless the book was made more directly useful to him. Doses were of major importance to the pharmacist, and it was their absence from the Pharmacopoeia, more perhaps than anything else, which had prevented him from using the book to a greater extent. His most important duty, in connection with every prescription which he dispensed, was to see that the physician had not, either by carelessness or by ignorance, prescribed excessive doses, and a book which professed to be his guide, but did not guide him, in this important duty failed to impress him as a book invaluable to him. Perhaps, after all, he was not much to be blamed if he preferred the dispensary, because he found it to supply what the Pharmacopoeia lacked, if not so authoritatively or so accurately as the Pharmacopoeia would. And this preference of the average pharmacist for the dispensary was a hint which the author thought the revisers of the Pharmacopoeia of 1900 should heed seriously.

That both pharmacists and physicians had in truth been disappointed in the Pharmacopoeia because it did not contain doses, and that they would like to have it contain them, had been well proved by their responses to inquiries which had been sent to them within the last year or two. When asked whether doses should be included in the Pharmacopoeia, 264 out of 311 Missouri physicians had replied in the affirmative, and the committee of the Medical Society of the State of New York, which had for two years been striving to obtain the opinion of medical men as to the Pharmacopoeia, had received such a preponderance of replies in favor of the introduction of doses that it had recommended this step, among others, in its report to the society. So much for the evidence of physicians. Of sixty-two Ohio pharmacists to whom the same question had been submitted by a committee of the State pharmaceutical association, only one had replied in the negative. There was little doubt, then, that if doses were to be introduced into the Pharmacopoeia (particularly in connection with other changes made for the same reason, such as the introduction of the more important synthetics) the book would be looked upon with much more favor by pharmacists and physicians generally, and would in time spring into a much larger use.

Not only was the introduction of doses into the Pharmacopoeia desirable for the reason that it would greatly increase the use of the book, however; it was desirable and necessary for its own sake alone. There should certainly be some authoritative standard in pathology. The physician should have some guide which represented the crystallized experience and opinion of his profession, and the pharmacist, whose duty it was to act as a safeguard to the physician, and who was held
responsible if he failed to discharge this duty, should have some definite and authoritative ground of judgment. The Pharmacopoeia set the standard of medicaments in all respects save that of doses; it should, in view of its necessity and importance, set the standard in this respect also. That this should be done had been urged by the pharmacopoeial revisers of other countries. The English, the German, and nearly every other pharmacopoeia of importance, save that of the United States, contained doses.

Against the introduction of doses into our Pharmacopoeia three objections had been urged. The first one was that, if the prescriber exceeded the doses designated in the Pharmacopoeia, he would perhaps render himself amenable to the law for so doing, if, perchance, his patient should die or if some enemy should bring suit against him for malpractice. This objection was more academical than practical; it was based more upon fancy than upon fact or reason. In the first place, a prescriber would so very rarely exceed the maximum pharmacopoeial dose that the point was scarcely deserving of any consideration. Indeed, he would hardly ever exceed the maximum dose except in giving an antidote in case of poisoning, or, perchance, in giving morphine to a person addicted to morphine. But, even supposing for argument's sake that he should do so, and that he would immediately be sued by some designing enemy lying in wait, he would have no difficulty, if he were innocent, in proving his innocence to the court. If his act had not been within the bounds of science and reason, he must of course expect to suffer the consequences, and should, indeed, be made to suffer them; but if he had acted competently he could readily show sanction of his act in the book of some prominent therapeutist. The Pharmacopoeia was a book of standards, true; but there was nothing to prevent the physician from departing from its standards if he so desired. If he preferred to use a tincture of digitalis which was of twice the pharmacopoeial strength, he rendered himself liable to no legal punishment. So, also, he might with impunity exceed the pharmacopoeial dose of any medicine so long as he did no harm thereby; and if he did do harm, and was punished for it, he was not punished because he violated the standards of the Pharmacopoeia, but because by incompetence or carelessness he endangered or destroyed life. But to make doubly sure immunity from punishment for exceeding a given pharmacopoeial dose, the doses could be so stated as clearly to give the prescriber liberty to exceed them in the very rare cases where it would be necessary. Perhaps a clause to this effect, inserted among the preliminary notices, would serve the purpose.

The second objection which had been made against the introduction of doses was that the Pharmacopoeia was a book of arbitrary and definite standards: there could be no arbitrary and definite standard in doses, because hardly any two authorities in therapeutics stated the same dose of any given medicament. This, the author believed, was an erroneous conclusion drawn from an exaggerated statement. The disagreement between medical authors in the giving of doses was not a vital one. In the comparatively few cases in which it was found it was most often in connection with non-toxic drugs, which did not much matter, and rarely with toxic drugs, concerning which the question of dose was one of importance. Moreover, this disagreement was usually with respect to average and not maximum doses. The disagreement among medical writers over maximum doses, particularly of those drugs with which the matter was one of importance—the toxic ones—was not enough to prevent the medical members of the revision committee from deciding upon doses which would not only represent the consensus of opinion, but be as near to scientific accuracy as was possible in posology. But, even if it were possible to get only what might be termed approximate doses, these would serve the purpose. For the purpose was to get doses which were representative of general practice and experience, and would enable the pharmacist to know authoritatively when an excessive dose had been prescribed, but which the physician might depart from in those rare cases in which he deemed it necessary, indicating on the prescription, by a star or exclamation point, that an extraordinary dose had purposely been ordered, as he always should when ordering such a dose.

The third objection which had been urged against the introduction of doses into the Pharmacopoeia was that they were entirely foreign to the original purpose and scope of the work. The purpose of the Pharmacopoeia, it was argued, was to prescribe standards for the selection, preparation, nomenclature, character, strength, and purity of the medicaments authorized by it; it had nothing whatever to do with the use of these medicaments, any more than the national law which prescribed the standard of the gold dollar had to do with the number of gold dollars which should be paid for a day's work. This comparison was, in truth, misleading; the conditions in the two cases were not at all the same. But it is not the author's purpose to argue whether the introduction of doses would conform to the original purpose of the Pharmacopoeia or not; this, to his mind, was a point of minor importance. He had due respect for tradition, but he thought that when we failed to recognize that tradition had grown out of the conditions of the past, and that it could not apply without modification to the conditions of the present, if these had materially changed, we were devoid of that power of adaptability which had always and would always determine the survival of the fit; we showed ourselves incapable of meeting new conditions and of realizing that the times changed and we must change with them. If the Pharmacopoeia were the product of a single author and intended only for whoseower might choose to buy it, as most books were, a narrow scope might be desirable. But the Pharmacopoeia, on the contrary, was a book of standards created by the professions of pharmacy and medicine, and as such it was intended to be used, and should be used, if its purpose was to succeed fully, by every pharmacist and physician in the country. It had been proved that the traditionally narrow scope of the Pharmacopoeia had prevented a more general use of the book; that the pharmacist, and more particularly the physician, did not often consult it, because he found it of too little service to him. In the face of this experience should we continue the old policy? Should we refuse, with the eyes open, to extend the scope of the Pharmacopoeia when we had the best of reasons for knowing that to extend it would materially extend its usefulness and therefore its popularity, and would not be in any way detrimental? Which was better, to have the Pharmacopoeia conserve the ethics of the revered men who had established its policy decades ago, and have it lie unpurchased and unused by the great majority of pharmacists and physicians, or to relinquish some of those now musty ideals, and make it so conform to the demands and needs of the pharma-
The Effects of Habitudal Train Journeys on the Business Man's Health.—The British Medical Journal for September 23d points out the seriousness of the injury inflicted on the users of the railways by the irregularity of the service. Common experience, it says, affords to every one of us ample familiarity with the ordinary trials of the railway traveler. The rush to the station to catch the train, which may perchance be punctual; the weary wait on draughty platforms or in stuffy waiting rooms; the dilatory journey—all these add seriously to the labor of the day even in the best of times; but when the weather is cold and damp they are still more injurious, in that they are largely responsible for those "cold," as they are called, those conditions of depressed vitality which are the starting points of most of the acute diseases from which men suffer, and from which the elderly and the feeble die. But outside and beyond these well-recognized evils, the unpunctuality of a railway service does a daily injury to those who depend upon it as a means of reaching their place of business by adding to that nervous strain which is the really hard part of a business life. An unpunctual railway, in fact, hits a business man in his most vulnerable spot. It is on the crisp activity of his mental processes that his livelihood depends, and the evil effect of the unpunctual morning train is not merely that it makes him arrive late at his office, but that it causes him to begin his work weary and annoyed. People talk about the "nervous strain" of railway traveling, which many folk, even medical men, attribute to "vibration" and high speed. Perhaps in long journeys in third-class carriages, where there is no rest for the head, vibration may have something to do with it; and as to high speed, if people persist in looking out of the windows, of course they suffer in consequence of the visual disturbances produced. But it is to be noted that experienced travelers always rush to quick trains, and especially to those that stop as seldom as possible. It is the worry of delay and the anxiety as to the time of arrival, which is the great cause of nervous strain, that "tired feeling" with which most suburban-dwelling business men arrive in London. This, repeated day after day, undoubtedly has an evil and wearing effect on the nervous system. But it does harm in other ways, which are less obvious, but none the less effective, and this especially to people beyond middle life. The two great causes of high arterial tension in such people are worry and chill, and the one great remedy—practically the only remedy which can be got away from home—is alcohol. Thus it happens that when the city man arrives from his suburban home, chilled, worried, and late, with the stopcocks on all his blood-vessels so that his brain is starved and he can not think, the craving for a "nip" of alcohol—the only available vasodilator—becomes overwhelming, and this morning drag is too often the beginning of the end. The more we consider this matter, says the Journal, the more convinced we are that the city man seeking for a suburban residence should study the punctuality of the train service rather than go by its advertised speed as described in those mendacious documents commonly spoken of as "time tables."

The Heart of Dr. Livingstone.—According to the Gazette médicale de Paris for September 2d, the British South Africa Company has offered to the Livingstone Memorial Committee to reserve near Lake Nyassa a piece of ground, one hundred acres in extent, around the spot where the heart of Dr. Livingstone is interred. The Livingstone Memorial Committee has gratefully accepted this gift, and has decided to erect upon the site a granite column forty feet high destined to perpetuate in South Africa the memory of the illustrious medical explorer and missionary.

Death of Professor Stoerk.—The Lancet for September 23d announces that Professor Karl Stoerk, the well-known laryngologist, died on Sunday, September 17th, at Hietzing, near Vienna, in his sixty-seventh year. He was a pioneer of much modern laryngology and the author of treatises on the use of the laryngoscope published a quarter of a century ago.

Death of Dr. Jules Simon.—The British Medical Journal for September 23d announces the death of Dr. Jules Simon, physician to the Hôpital des enfants malades, Paris, which took place recently from heart disease following influenza. Dr. Simon was recognized as one of the foremost living authorities on diseases of children.

The Uses of Play.—Dr. Burnham (Sanitarian, October), in an article on Ventilation and Cleanliness in the Schoolroom, has the following excellent remarks on play:

"The largest psychological benefit of play is that it leads to quick judgment and adaptability. Children who are brought up away from their fellows are dreamy, living in several worlds. Such children are more thoughtful and have broader natures, but lack adapting power. Play, physically, gets one into the habit of doing things for the pleasure of doing them. Play increases the capacity of the individual for action.

"Another, social rather than psychological, point is that play lengthens the period of childhood. To be free to grow until one is twenty or twenty-five, perhaps, lays the foundation for future greatness. Play, in keeping up childhood interest, preserves the vigor and optimism of youth."
Original Communications.

VERY EARLY RUPTURE IN AN ECTOPIC GESTATION IN A TUBAL DIVERTICULUM.

By FERNAND HENROTIN, M.D.,
PROFESSOR OF GYNECOLOGY IN THE CHICAGO POLyclINic,
AND
MAXIMILIAN HERZOG, M.D.,
PROFESSOR OF PATHOLOGY IN THE CHICAGO POLyclINic.

As is well known, rupture in tubal pregnancy, occurring during the first month, is comparatively rare. The infrequency of the condition is, of course, proportionate to the time which has elapsed since the implantation of the ovum into the tubal mucous membrane.

Cowles * has recently reported a case of rupture of a tubal pregnancy, probably in the fourth week. This has caused Lamb † to communicate a report of a post-mortem in which rupture was claimed to have occurred in a case of tubal pregnancy at about two weeks. Lamb's description, however, is too meagre to be accepted as conclusive evidence.

Parry ‡ cites a case reported by Cathcart § of a rupture in the third week of extra-uterine gestation, and one reported by Rokitansky, || in which a rupture is claimed to have taken place as early as the first two weeks of ectopic gestation.

The case about to be reported is undoubtedly one of very early rupture in an ectopic gestation, and is the more interesting as it evidently had its seat in a diverticulum of the main tubal canal. This location of an ectopic gestation has been observed in very few cases; one example of this variety was observed and reported by the authors a short time ago. The microscopic examination clearly demonstrates that the early rupture must have been directly due to the fact that gestation occurred at a point in the Fallopian tube which from the first had an extremely thin wall on one side.

Case.—Mrs. M. A., forty years old, Swedish, housekeeper. Parents alive and well. One sister died of heart disease, otherwise the family history is negative. Patient first menstruated at the age of thirteen; menstruation was regular and normal in all respects. In 1889 she was married, and two years later her first child was born. Pregnancy and labor were normal, but the child was small and poorly nourished, and was sickly until its third year. The patient again became pregnant about four months ago, and thinks she had a miscarriage at about two or three weeks. At this time she passed clots and a great deal of fluid blood. The flowing continued intermittently for about three weeks. From this time on she menstruated every three weeks. The amount of the menstrual discharge was about the same as that of the menstruations prior to the miscarriage above mentioned, but it was less sanguineous.

On August 12, 1898, the patient menstruated as usual; three weeks later, or about September 2d, she had the usual menstrual phenomena, but no flow appeared. On September 24th, while in a large dry-goods store, she was seized with very severe cramps in the lower part of the abdomen, more particularly on the right side. Soon after the onset of this attack she vomited, and, after great difficulty, was able to reach her home. By this time the pain was not quite so severe, but was still present.

Despite the fact that the pain was less intense, the patient grew rapidly weaker and had repeated attacks of vomiting. She then noticed a swelling or enlargement of the abdomen and her family and friends observed that she was growing rapidly paler, that her extremities were cold and her body bathed in cold perspiration. The patient herself complained of intermittent pains, and said that she felt as if she was going to have a baby. During the train of symptoms just described there had, however, been no vaginal discharge of any kind.

Dr. Henrotin was sent for, and, from the history given, the subjective symptoms, and the physical examination, made a diagnosis of ectopic pregnancy with rupture.

The patient was at once taken to the Polyclinic Hospital, and on September 25th, at 1 A.M. — that is, nine hours after the first manifestation of symptoms of rupture — an abdominal section was made. The operation confirmed the diagnosis of ectopic pregnancy.

Fig. 1.—Ruptured Fallopian tube natural size. a, site of rupture with blood coagulum; b, open fimbriated extremity; c, ovary with corpus luteum.
The patient recovered without any incident.

Description and Microscopic Examination of the Specimen Removed.—The specimen removed included the greater part of the left Fallopian tube and of the ovary of the same side. The tube as a whole appears to be somewhat, but not materially, thickened. The length of the removed portion is six centimetres; its thickness, nine millimetres; the fimbriated extremity is comparatively small, but its place are well developed. A small pedunculated hydatid of Morgagni, $6 \times 3 \times 2$ millimetres, is seen on the anterior surface of the ampulla. The tube wall is ruptured at a point $2.5$ centimetres from the outer margin of the fimbriated extremity. The opening is elliptical in general outline, and is two centimetres in its greatest diameter, which is parallel to the long axis of the tube. The margins of the rent are as thin as fine paper and are curled and rolled outward upon themselves. A blood coagulum $8 \times 7 \times 6$ millimetres in extent protrude out of the tear in the tube wall and is firmly adherent to the latter. The fimbriated extremity is open, and on making a vertical medi-an incision into the ampulla and the isthmus external to the rent the tubal canal is found to be very tortuous.

The portion of the ovary removed measures $3.4 \times 2.3 \times 1.6$ centimetres and shows a large typical fresh and still gaping corpus luteum $1.9 \times 1.8 \times 1.6$ centimetre in measurement. The greater part of the corpus luteum cavity is filled in with yellowish tissue, and the defect is in the form of a shallow depression.

The ovum and embryo were not found at the time of operation, as is so frequently the case in operative procedure for the relief of the conditions following rupture in ectopic gestation.

In estimating the age of an ovum or embryo from the clinical data we must always remember that the product of gestation may have originated either from an ovulation about the time of the last actual menstruation or from the time of the first catamenial period missed. This should always be taken into consideration because, otherwise, we are liable to make serious mistakes.

Judging from the clinical data in our case, the ovum was either two to three weeks or five to six weeks old, providing that ovulation as well as menstruation occurred at intervals of three weeks. When the size of the tube and of the rupture are taken into account we are compelled to infer that the ovum could not have been older than two to three weeks, because an ovum five to six weeks old could not have been accommodated in the tube, as it appeared at the time of removal, nine hours after rupture—that is, before any material changes could have occurred.

As the tube wall at the site of rupture was extremely thin, and could have contained only very minute blood-vessels, which could have given rise to only an insignificant amount of hemorrhage, the hemorrhage which caused the urgent symptoms in the case must have come from the tubo-placental sinuses.

Microscopical examination shows that the ovum had made its escape from the tube. The only embryonal structures found are syneytrial buds, which are either attached superficially to the tubal decidua or imbedded in the latter. The syneytrial buds, however, do not show any degenerate changes. The tubal decidua shows a fairly well differentiated compact and spongy layer. Canalized fibrin is not found excepting in a very thin, insignificant layer in a few places.

The sections examined were taken from places opposite to the site of the blood coagulum and rupture, and also from locations external and internal to this point. The tubal canal was found to be preserved throughout its entire extent. In a zone extending through only a small number of sections one side of the canal still shows simple, flattened, and drawn-out plicae lined with flattened cuboid epithelium. The connective tissue on this side, while it shows marked changes, does
not present any well-marked typical decidual cells. Toward the other side of the tube the epithelium disappears, and is replaced by a tissue which presents decidual characteristics. In all other places the main tubal canal shows complicated folds lined with columnar epithelium, in some places ciliated. The connective-tissue core of the placenta, while it shows marked changes—namely, dilated blood-vessels and enlarged cells—does not present the characteristics of a typical decidua, as no decidual cells can be found.

From a careful examination of many sections, it appears that the ovum could not have been located in the main tubal canal, which is preserved throughout its entire extent, but that it must have developed in a diverticulum originating from the main canal. This diverticulum was probably located at the point above referred to, where, within a very small space, the upper and lower circumference of the tube presented such different characteristics. The ovum must have been located in this branch of the main canal and not in the main canal itself, which shows only slight decidual changes, and which was not laid open by the rupture.

A few words could be added with reference to the muscle fibers and blood coagulum. The muscle fibers around the main tubal canal are enlarged and hypertrophied. They are, however, rarefied, and open interstices—diastases—are seen between the different bundles of fibers and even between the individual fibers. Opposite the point of rupture, and between it and the tubal canal, the muscle fibers are especially hypertrophied and the rarefaction is particularly prominent.

In the blood coagulum, which is adherent to the tube at the point of rupture, a dense, firm network of fibrin is seen. The red blood-corpuscles are well preserved as regards their shape and color, and hematoxyl granules and crystals are absent. This demonstrates that the blood coagulum was recent and could only have formed shortly before the operation.

From the history of the case, and after consideration of the macroscopical and microscopic examinations of the specimen obtained by operation, the following conclusions may be drawn:

In this case an ectopic pregnancy occurred, located in a diverticulum of the tubal canal. This diverticulum was short and very probably traversed the fibers of the muscular coat outward in such a manner that it was covered by only a very small amount of tissue. The very thin outer covering of the diverticulum gave way very early in the course of the pregnancy—not later than the third week—under the influence of pressure and pressure atrophy, and a rupture and hemorrhage from the placental site occurred.

At the time of this occurrence the ovum must have been alive, because there are no signs of previous hemorrhage or degeneration of the decidua and syncytiat buds.

Whether the diverticulum was congenital and due to an embryonic anomaly, or acquired in later life in consequence of a pathological process, is a question which we are unable to answer.

**A REPORT OF TWO CASES OF ACCESSORY THYROID GLAND AT THE BASE OF THE TONGUE.**

*By ARTHUR W. WATSON, M.D., PHILADELPHIA.*

The occurrence of tumors at the base of the tongue composed of thyroid tissue is sufficiently rare to make of interest a report of the following two cases:

**Case 1.**—Mrs. Elizabeth D., aged fifty years, came to the Howard Hospital in May, 1898, complaining of great dyspepsia and difficulty in swallowing. She stated that there had been a lump in her throat for eight or ten years, but it had given little trouble until recently, when it had begun to enlarge, producing the symptoms for which she sought relief. The patient's general health was not good. She was weak and somewhat emaciated. Direct inspection of the throat showed a rounded tumor rising behind the arch of the tongue, having a whitish patch on the top (Fig. 1). With the laryngeal mirror it was seen that a large, smooth tumor occupied the base of the tongue from the epiglottis, which it pressed backward, to the circumvallate papilla. To the finger it felt smooth and firm. It was about an inch and a half long, an inch wide, and an inch thick. It was ulcerated on the top, the ulcer being covered by a white slough or membrane. An attempt was made to remove the growth with the galvanocautery snare, but, the current not being strong enough, the loop slipped over the tumor, removing only a portion of membrane. A second attempt having no better result, further effort at removal, on account of the patient's conditions, was deferred. A small, rather superficial piece of the tumor was removed and given to the pathologist for examination. The patient was put to bed and carefully watched, and in about ten days the growth had become reduced in size sufficiently to remove the immediate necessity for interference, and as I was ignorant of the nature of the tumor I thought it better to wait. The microscopic examination at the time was not entirely satisfactory, and it was not until after having found the second case, four months later, that a reexamination of the specimen revealed its true nature. The pathological report at the time was as follows:

"Microscopically the sections consist in great part of tissue the seat of excessive inflammation and necrosis, without tangible evidence of tuberculosis. In one corner there is a small circumscribed area, about half the size of a split pea, surrounded by an area of hemor-
rhage, consisting of cells arranged in alveoli, supported by a rather delicate stroma of connective tissue. The alveoli are irregular, narrow, and tortuous. The cells are distinctly epithelial and stain well, both nuclei and nucleoli. The cells are usually in but a single layer. There is a distinct membrana propria. Sections were stained for tubercle bacilli in tissue, but none were found."

Case II.—Anna E., a colored girl, aged sixteen years, came to the Philadelphia Polyclinic in September, 1898. She complained of something growing in the throat that interfered with swallowing. A lump had been present, to her knowledge, for five years, but had only of late given much trouble. Examination showed a smooth, rounded, firm, and elastic tumor on the base of the tongue, in the median line, between the epiglottis and the circumvallate papillae. It resembled in every respect the first case, except that it was not ulcerated.

Under cocaine anaesthesia the growth was surrounded by the electric-cautery snare and removed. Subsequently the wound healed promptly, leaving a smooth and apparently normal tongue. The tumor, after removal, measured an inch and three eighths in length, an inch and an eighth in width, and three quarters of an inch in thickness (Fig. 2). It was submitted for examination to Dr. H. L. Williams, who gave me the following report:

"Macroscopic appearance: The growth is surrounded by a fibrous capsule. It is soft, spongy in appearance, and a delicate reticulum of fine filaments extending all through is clearly apparent to the eye. The surface is reddish, and in some areas whitish, glistening in appearance, and resembles the structure of the thyroid gland.

"Microscopically, the growth presents a meshwork of acini which are separated by an exceedingly delicate reticulum of connective tissue. The acini are almost universally dilated and cystic and filled with colloid material which contains many vacuoles. In some of the acini the granular debris contains leucocytes, and partially disintegrated red blood-corpuscles are also found. Lining the acini is found a single band of epithelial cells whose nuclei take the stain deeply. The outline of the cell substance can not be clearly distinguished. The nuclei appear granular and without carvocinetic figures, the epithelium being decidedly flattened by pressure. In some areas the epithelium is profusely proliferated and scattered throughout the stroma. The stroma for the most part is made up of fibrous tissue with few nuclei, and contains numerous well-formed blood-vessels filled with blood. The diagnosis of cystic thyroid tissues undergoing colloid degeneration is easily established." (Figs. 3 and 4.)

In a careful search through the literature it appears that very few such cases have been reported, and that the condition is probably quite rare. In 1892, at a meeting of the American Surgical Association, Dr. J. Collins Warren, of Boston, reported a similar case in a woman aged fifty-two years. In his article Dr. Warren mentions the report of two similar cases by Mr. Henry T. Butlin in 1890, who also collected six other reported cases. I have been able to find only the two following cases reported since 1892:

C. H. McIlraith (British Medical Journal, 1894). This was in a girl aged seventeen years. A tumor at the base of the tongue of the size of a small walnut. It
gave no trouble except that speech was rather thick. The larger part was on the right side. Under chloroform, the mucous membrane around the base was cut with scissors, the tumor caught with tenaculum forceps and separated, partly by raspatory, partly by snare. Bleeding profuse but controlled by pressure. Recovery.

J. H. Reintjes, Nymegen, at a meeting of the Laryngological, Rhinological, and Otological Society of the Netherlands, held May 22, 1898, reported a case of like nature. A man, twenty-five years of age, who had had several severe haemorrhages, was found to have a swelling, dark brown, smooth, elastic, covered with enlarged veins, occupying the base of the tongue, between the circumvallate papillae and the epiglotis. Electrolysis having been unsuccessful, operation was performed. A Trendelenburg's cannula was introduced into the trachea, the tongue was pulled forward, and the anterior pillar of the fauces was divided. The capsule of the tumor was split horizontally, and the mass shelled out without much bleeding. Recovery was excellent. This is the only case occurring in a male that I have been able to find, all the others being in females.

Strange to say, these tumors are not mentioned in any of the works on diseases of the nose and throat with which we are most familiar, including those of MacKenzie, Cohen, Browne, Bosworth, Ingals, and Sajous. McBride, in his last edition, mentions "thyroid-gland tumors" among others that may occur in the tongue.

Thyroid tumors in this position are developed from a persistent upper part of the thyroglossal duct, which is formed in the development of the thyroid gland, and opens at the base of the tongue at the position of the foramen caecum. The thyroglossal duct is usually obliterated after the eighth week of fetal life, but may persist, in whole or in part, throughout life.

For the microscopical examinations and reports in both cases, as well as for the photomicrographs of the tumors, I am indebted to Dr. H. L. Williams, pathologist to the Philadelphia Polyclinic.

THE CAUSE OF DEATH FROM INDUSTRIAL ELECTRIC CURRENTS.*

By R. H. CUNNINGHAM, M.D.,
CLINICAL ASSISTANT IN NEUROLOGY, VANDERBILT CLINIC,
COLUMBIA UNIVERSITY, NEW YORK.

Since the pioneer experiments upon the cause of death by electricity were made for the first time by Nollet much has been said and still more has been written, especially within the past twenty years, on the subject of death by electricity. To review and criticize

* The experiments described in this paper were performed in the physiological laboratory of Columbia University through the courtesy of Professor J. G. Curtis, to whom the writer is inexpressibly indebted for the many facilities so kindly placed at his disposal.

in detail the many extraordinary and peculiar opinions and theories that have been offered by the numerous investigators to explain the awe-inspiring and mysterious phenomenon of death induced by the electric current, although very interesting from an historical standpoint, would probably occupy more space than it is intended that this entire paper should occupy. In fact, though the literature on the subject of death by electricity is extensive, comparatively few of the experimental researches of the many investigators of this subject have been carried out except in a very crude way, and in consequence many undoubtedly erroneous conclusions have been arrived at simply because the experiments were not made in a truly scientific manner. In general, all previous investigators of the subject universally agree that if a strong continuous or alternating current of high tension is passed through the head and trunk, or even through the trunk alone, instantaneous death, or a condition so closely resembling death as to be indistinguishable from it, may be produced. Whether this condition is in all instances that of absolute death, or whether it is a variety of syncope with suspension of the respiratory function, leading ultimately to death if artificial respiration is not practised, seem to be questions on which scientific opinions differ, in spite of the existing accumulation of evidence that clearly disproves the latter explanation of the lethal effects of the electric current.

According to d’Arsonval,* the electric current produces death in one of two ways:

1. By direct action, the tissues being altered mechanically by the disruptive action of the current.

2. By reflex or indirect action affecting the nerve centres.

When the action of the current is as in No. 1, d’Arsonval concludes that the death produced is absolute and final. In the second case experimentation led him to the conclusion that the apparently moribund individual can usually be restored by artificial respiration if it is begun immediately after the accident.

But the result of later researches (Tatum,† Jones‡ Houston and Kennelly,§ Bleie,∥ Oliver and Bolam,¶ and others), so far from substantiating the hypothesis of d’Arsonval, clearly lead one to the conclusion that neither the results of experiments on animals with strong electric currents, nor the numerous reports of the pathological findings in the bodies of men killed

Comptes rendus de la Societe de biologie, 1887, No. 8, t. iv, p. 55.

accidentally by the electric currents of commerce or legally electrocuted by the high-tension current such as the State of New York employs, are in the least corroborative of that hypothesis. In fact, all of the more carefully conducted experiments (Tatum, Jones, Bleile, Oliver and Bolam) clearly indicate that in the higher animals the chief lethal effect of both the continuous and the alternating current is due to their action upon the heart, a result that is most clearly corroborated by my own experiments. Furthermore, it has been observed (Tatum, Jones, Houston,* and others) that in order to produce a fatal issue very much stronger currents are necessary when the electrodes are applied to both sides of the head, or one electrode on the head and the other just caudad the occiput. Thus Houston passed as much as six amperes directly through the head of a dog without producing death. Such observations are also fully substantiated by my results, and as all of my experiments without exception lead to the conclusion that if rapid death occurs from a very brief contact with a wire or wires conveying one of the commercial high-tension electric currents, the lethal effect is due entirely to the action of the current upon the heart. What the action is, however, none of the various writers tell us definitely, except that the cardiac effect occurs just as readily after the exclusion of the action of the vagus nerve by the administration of atropine or curare (Tatum). Whether the heart muscle is merely paralyzed by the current, whether it is killed from molecular changes produced by the current, or whether it merely comes to a standstill from its inability to overcome the enormous resistance, rarely present in my experience except under special conditions, that is stated by Bleile to result from the sudden contraction of the peripheral arterioles, are all opinions that seem to be merely theoretical. Therefore the object of this paper is not to investigate the well-proved fact that strong electric currents can produce death, but to reemphasize the effect produced by the current upon the heart, to elucidate the nature of that action, and finally, to devise, if possible, a more reliable method of resuscitation than that of artificial respiration, the only, and almost invariably futile, method in vogue in electrical accidents at the present day.

About five years ago the writer performed a number of experiments on dogs for the purpose of determining whether a contact of 0.5 second with the continuous 1,000-volt arc-light current, the 500-volt trolley-car current, or the continuous 220-volt power current was capable of producing rapid death in medium-sized dogs. Although the experiments were rather crude, owing to the lack of the proper physiological and electrical registration apparatus, it was shown very satisfactorily that even the comparatively low-tension power current possessed sufficient electro-motive force to send a lethal strength of current through an etherized dog when the resistance at the points of application of the electrodes was minimized by thoroughly moistening the skin and hair, or by shaving off the hair at those points and wetting the skin with a strong warm salt solution.

As only the continuous 115-volt illuminating current and a current of 124 volts from a large battery of accumulators were convenient for the present research, only these currents were employed in the experiments described below. As quite a number of fatal accidents from contact with the 110- to 120-volt current have been reported in recent years (Hansen,* Dr. V. F.,† and Hankel ‡), it was very probable that the currents at my disposal were of sufficient voltage to produce the desired effect in a dog, especially if care were taken to have good electrical contact at the points of application of the electrodes. That such was the case is clearly shown by the following experiment:

**EXPERIMENT I.—A medium-sized dog was etherized and a cannula inserted into the right carotid artery and connected to a Ludwig manometer that recorded upon the paper of a Hürtthle kymograph. In the trachea a tracheal cannula was inserted, through which the anaesthetic was administered when necessary. After carefully shaving the chest over the heart or over the abdomen the negative electrode, moistened with a strong hot salt solution, was firmly applied to that region by strips of rubber plaster. The cup-shaped positive electrode was then applied to the head over the cerebrum after the superficial layers of the scalp had been previously dissected from the underlying skull and temporal fascia. To minimize the resistance at the points of contact, both electrodes were covered with thin chamois skin, well soaked in hot salt solution. To record the respiratory movements, a stethograph was attached to the chest by rubber plaster or tapes, and connected to a recording Marcy tambour. A chronograph—the upper in the tracings—being in shunt with the circuit that passed through the dog served to inscribe the base line as well as to mark the closing and the opening of the circuit. A second chronograph, the lower, indicated the time in two-second intervals.

To measure the strength and voltage of the current a Weston deadbeat ammeter and a Whitney deadbeat voltmeter were used.

After a normal tracing was taken the current was suddenly closed and kept closed for seventy-six seconds, during which time 0.4 ampère at a pressure of a hundred and sixteen volts passed through the dog and produced the following effect (Fig. 1).

Almost simultaneously with the closing of the circuit the blood pressure rapidly fell to zero, a few heart beats (auricular) being perceptible in this tracing. At the closure of the circuit a deep inspiration was produced, then a deep expiration followed by cessation of respiratory movement in a state of expiration during the passage of the current. On breaking the circuit a deep inspiration followed by an expiration resulted.

---

† Dr. V. F. in O. Aerzliche Cental-Anzeiger, 1897, S. 415.
and after a few moments a few shallow respirations took place. Attempts at restoration by artificial respiration were then begun and continued for twenty minutes, but were entirely ineffectual.

Thus the conclusion is evident that the continuous, finely pulsatory, 116-volt current can readily kill a dog. Immediately both ventricles stop beating, while the auricles, especially the auricular appendices, beat with extreme rapidity. On stopping the current the auricular appendages generally resume their usual coordinated, rhythmic rate of contraction, which may continue for a considerable number of minutes. Frequently the auricles also begin to beat again coordinate\_ly for a few seconds, but the ventricles very rarely ever exhibit the slightest sign of a coordinated contraction. So rare, in fact, is the spontaneous recurrence in the dog of even a few feeble coordinated beats of the ven-

![Fig. 1](image1)

![Fig. 2](image2)

ther, it is evident from the tracing that an almost instantaneous and total extinction of the arterial circulation is produced. That this extinction of the blood pressure results from a practically instantaneous cessation of the coordinated rhythmic contractions of the ventricles of the heart is readily demonstrated, for all that is necessary is to observe the behavior of the heart, after previously opening the chest, at the instant a current of 0.9 ampere, or even less, is passed through a
tricles after such powerful shocks that I have noted it in but one experiment, and then only after a tube had been passed into the ventricle via the right jugular vein in order to withdraw venous blood from the greatly distended heart. Very evidently, therefore, the current affects chiefly the ventricular portion of the heart muscle.

 Passage of the Current Directly through the Chest. — When the current is conducted directly through the thorax by attaching the electrodes to the forearms, or if one electrode is attached to the left forearm and the other is placed on the chest immediately over the heart, the resultant tracing differs in one respect from that obtained in the preceding experiment. This difference, as is very evident from the accompanying tracings (Figs. 2 and 3), consists of the greatly exaggerated respiration that occurs during the passage of a current that is of an ample lethal strength. This effect is well shown in the following experiment:

 Experiment II. — Mongrel dog, weighing 8,654 grammes. Procedure as in Experiment I. Current = 1.5 ampères; volts = 115. Duration of shock, three seconds. Electrodes on forearms. Effect: Immediate tetanic contraction of muscles of fore limbs and hind limbs, which lasted during the passage of the current; momentary contraction of the muscles of the trunk. Rapid and exaggerated respiration, which, after thirteen seconds, became gradually slower and feeble, and finally ceased at the end of two minutes. Almost immediately after closing the current the blood pressure rapidly fell and the heart soon ceased apparently to beat.

 In other experiments with currents of less or of greater strength applied through the forearms, or through a forearm and the front of the chest, while the same general effects were produced, the fall of blood pressure and cessation of the heart beat occurred practically simultaneously with the closing of the circuit.

 To get a more definite idea of the average minimum strength of the continuous current that is required to produce a fatal effect in the average dog, when it is passed immediately through the chest, numerous experiments fashioned after the plan of Experiment II were made. In these experiments continuous currents of various strengths were passed for different periods of time through the chests of dogs of different weights and ages. Briefly summed up, the results of this series indicate, first, that young, well-nourished, and hardy dogs can usually withstand a slightly greater strength of current through the chest for a longer time than ill-nourished or older dogs. Secondly, that the minimum strength of current required to stop the hearts of different dogs bears no definite ratio to their size and weight, for I have seen frequently the heart of a very large dog, such as a Newfoundland, instantly stopped by a current of but 0.3 ampère, while the hearts of very small shaggy terriers, although usually considerably affected, not only readily withstood repeated shocks of a current of 0.45 ampère, lasting from ten to eighty seconds, but quickly recovered from the shock of a current of 0.7 ampère that was applied for two seconds and a half. Thirdly, that the duration of the shock must occupy a certain amount of time to cause the heart to stop its coordinate beats. But what the exact relationship is I have been unable to determine, because the hearts of different dogs differ greatly as regards their susceptibility to continuous currents of different strengths conducted through the chest for different lengths of time. Thus in some dogs a current of 0.25 ampère for one second causes the heart to stop permanently its coordinate beats. In other dogs, which
were as nearly like the former as possible, it was found that even 0.45 ampère applied through the chest for over a minute failed to stop the heart. In other dogs repeated shocks of 0.6 ampère for periods of from two to fifty seconds failed to stop the heart permanently. Currents of from 0.65 to 0.75 ampère were then sent through the chests of these dogs for two seconds, but in each instance complete recovery of the blood pressure, which is always very prompt when it is going to occur, quickly followed. Finally, after ten minutes had passed, the former current of 0.6 ampère, that had been borne previously without harm, was applied for two seconds, and almost coincidently with the closure of the circuit the heart of each animal ceased permanently to beat. Further, certain dogs may be given at intervals of about one minute in the early stages of the experiment a number of succeeding shocks, each a little stronger than the other, until a current strength of from 0.45 to 0.6 ampère is reached, which amounts many dogs will bear without the occurrence of a stoppage of the heart. Then, if some severe operation that usually produces more or less profound general depression even in a deeply anaesthetized animal be performed—for instance, if the cervical spinal cord be exposed and divided—frequently the very brief passage of a current of 0.35 ampère through the chest will cause the heart to stop immediately, although previous to the occurrence of the depression a current possibly as great as 0.65 ampère had been withstood readily. In other words, it seems that the heart of an anaesthetized dog, and probably also that of an unanaesthetized dog, is more susceptible to weak electric currents when the general condition of the animal is depressed. From the preceding results it is quite evident that to come to any definite conclusion regarding the exact strength of current of a certain voltage that is necessary to electrocute a dog is out of the question. In none of my experiments was a current strength of less than 0.2 ampère fatal, in spite of the fact that the current was passed directly across the chest so as to include the heart in the circuit. The maximum strength of current that failed to stop the heart and kill the animal was 0.75 ampère. However, the failure of a current of this great strength to kill was met with in but one dog, and then a rather small one, its weight being 5,005 grammes. Usually a current of from 0.6 to 0.65 ampère was sufficiently strong when passed across the chest to kill the majority of the dogs whether large or small. As large dogs often succumbed just as readily to currents of only 0.25 ampère, always in the same manner—namely, by an immediate and permanent cessation of the coordinated contraction of the heart—there seems to be ample ground for concluding that, besides the influence exerted by the quality, duration, strength, and density (Tatum) of the current through the thorax, some other factor, apparently residing in the heart and probably physiological in nature, also exercises a con-

siderable influence in the greater or less readiness with which the cardiac effect is produced. But the further discussion in greater detail of this physiological factor will be deferred until the effects produced by sending a very strong current directly through the cerebrum and medulla oblongata have been described and contrasted with those obtained in the above-mentioned experiments.

Effects produced by the Passage of a Strong Continuous Current directly through the Cranio-cervical Portion of the Central Nervous System.—So far as I have been able to discover, in none of the various experimental investigations upon the cause of death from high-tension electric currents has any observer exposed the cerebral cortex and upper portion of the spinal cord and applied the electrodes conveying the death-dealing current directly to those regions of the nervous system. A number of writers (Brown and Peterson, Tatum, Houston and Kennelly, Jones, and others) * have applied the electrode to the head and lower part of the back, or to the head and middorsal region of the back, or to the head and the back of the neck, and have produced death with greater or less ease with strong currents. Tatum concluded that much stronger alternating or continuous currents were necessary to produce death when they were passed from the head to the lower cervical region of the back, or vice versa, than when such currents were sent from the head through the thorax to the leg, or even through the thorax. Houston passed six ampères for a few moments directly through the head of a dog without killing it. Jones noticed that while 0.5 ampère of the continuous current could be passed through the head or upper part of the neck of an anaesthetized cat without affecting it much, an equally intense current through the thorax always proved fatal.

In the above-mentioned experiments in which the electrodes were applied to the skin the intensity of the current actually traversing the deeply lying nerve structures is naturally a matter for speculation, for though the ammeter indicates the total ampère of the current passing through the portion of the body between the electrodes, probably but a small part of this total ampère really traverses the deeply lying cord and brain. To minimize, the discrepancy arising from the above-mentioned cause, and to prevent as much as possible the escape of current to other conducting tissues and to the heart, a number of experiments similar to the following were made.

Experiment III.—Etherized dog. After the skin and temporal muscles had been dissected from the underlying bone, the cranial cavity was opened by a trephine applied to both sides. These openings were further enlarged by bone cutters until a large area of the cerebral hemispheres was uncovered. Along the course of the longitudinal sinuses a narrow protecting strip of bone was left. A hot, flat sponge was then

* Loc. cit.
placed upon the brain and the skin flaps temporarily replaced in their proper position. Next an incision was made through the skin of the upper part of the neck; the various muscles were then dissected from the upper cervical vertebrae, and finally the spinal processes and lamina of the five upper cervical vertebrae were removed so as to expose the spinal cord freely. After opening the spinal dura the horizontal narrow arm of an L-shaped electrode, entirely covered with rubber except on the lower surface of its horizontal arm, which was faced with chamois skin, was placed on the posterior surface of the cord and held in position by spring clips applied at the edges of the incision in the skin. The cerebral convulsions were then exposed by reflecting back the dura, and a cup-shaped brass electrode, covered on its convexity with rubber and lined with well-moistened chamois skin on its concave surface, was applied to the surface of the brain. Bread electrodes of thin sheet copper were applied also to both forarms. By means of a double pole, double throw switch, and an adjustable rheostat, currents of different intensities could be directed either through the thorax or through the brain and upper cord.

Tracing No. 2 illustrates very clearly how the blood pressure and the respiration are frequently affected by the passage of such a current as 1.1 ampere for one minute directly through the cerebrum, medulla, and upper cord, while in tracing No. 3 the effect of passing a current of only 0.3 ampere for six seconds through the thorax of the same dog is shown for comparison. In this instance the current through the brain gave rise to the usual deep inspiration, followed by expiratory standstill while the current was flowing. If the current is not applied for too great a length of time, in a few moments after it is shut off the respiratory movements generally recommence, often feebly at first, and soon return to their former normal rhythm and strength if the electrode on the head is prevented from unduly pressing upon the brain. In fact, in a number of instances, even with currents as strong as 1.6 ampère, I have noticed that the respiratory inhibition seems to cease or to be overcome after the current has been acting for a number of seconds, so that pronounced respiratory movements begin even though the current is still flowing through the brain and upper cord. Generally with currents of from 1.5 to two ampères complete inhibition of respiration obtains during the entire time the current is passing. Markedly different is the behavior of the blood pressure in such experiments from that observed in experiments I and II. After a slight rise, coincident with the general tetric spasm of the muscles which the closure of the circuit suddenly produces, the pressure falls slightly, and then slowly rises to a considerable height, frequently to twice or even nearly three times its original height, if the circuit is kept closed for about fifty seconds. If the current is broken at this stage the pressure may or may not continue to rise for a few moments, after which it quickly returns to the normal; but if the flow of current is allowed to continue for four or five minutes the height-

ened blood pressure slowly diminishes, the cardiac action becomes progressively more labored and slower, and, finally, the complete cessation of the heart beat announces the fact that the death of the animal has occurred. Quite otherwise, however, is the behavior of the blood pressure when artificial respiration is performed during the entire time that the current is flowing. Under such circumstances, although the slight initial rise and the slight subsequent temporary fall of blood pressure accompanied by more or less cardiac inhibition occur, the enormous rise in the pressure does not take place. Thus, on discontinuing the current at the end of a minute the inhibited heart action gradually disappears and respiratory movements, at first slow, soon become natural. Therefore, asphyxia resulting from the inhibition of the respiratory movements appears to be mainly responsible for the increased blood pressure.

In certain dogs, especially when rather stronger currents are employed, a series of severe general convulsions may commence a few moments after the current is closed, and, should such occur, the return of the natural respiratory movements upon discontinuing the current after an application of from thirty to sixty seconds is frequently quite tardy. In fact, occasionally the fatigue of the muscles and of the spinal and medullary nerve cells concerned with the respiratory function is so great that a dangerous, or even a fatal degree of asphyxia may arise before effectual respiratory efforts are made by the animal. Consequently, artificial respiration applied for a few minutes, or until the fatigue has passed off, invariably restores such animals completely.

Therefore, it is quite clear from this description that a dog may be killed by passing a strong continuous current for a more or less lengthy period through the brain and upper part of the cervical spinal cord. But the mode of death is quite different from that which results from passing the current through the body in such a fashion that the thorax, or rather the heart, is traversed by some of the lines of the current. In the former case, when death results from the more or less prolonged passage of a strong current directly through the exposed brain and upper spinal cord, the lethal effect is plainly the result of asphyxia, while in the second case, where the streams of even a moderate current traverse the heart for but a brief period, the lethal result is clearly due to the sudden and permanent stoppage of the heart's coordinated action, the central nervous system dying from anemia. Such being the case, it is evident that to produce experimental in the briefest possible time the death of an animal by means of the ordinary commercial continuous or alternating electric currents, the electrodes should be so placed that the greater portion of the current passes through the heart. Thus one electrode should be placed on the front of the chest directly over the heart and
patients to suffer indefinitely, hoping that something may occur to relieve them, when a comparatively simple and harmless operation would remove the trouble at once and prevent irreparable damage to highly necessary organs. In most early operations, where extensive destructive changes have not taken place, the danger in competent hands is next to nothing. Henry Morris, for instance, reports a hundred and thirty-two such operations with but two deaths.

The following cases have been selected with the idea of calling attention to certain interesting features:

Case I.—A woman, twenty-three years of age, well nourished, and not neurotic, had suffered for years with pain and tenderness in the region of the left kidney, the pain following the ureter to the bladder and often running down the thigh. Recently she had been almost completely disabled. The symptoms were increased by motion, and particularly by jolting.

Physical examination revealed nothing abnormal, which seemed to exclude movable kidney, tumor, hydronephrosis, etc.

Examination of the urine showed absence of albumin, sugar, and pus, with presence of innumerable crystals of calcium oxalate, together with a few hyaline casts and red blood-corpuscles. As the patient was menstruating, it was thought that this might account for the blood, but catheterization failed to eliminate it. It was then imagined that the passage of the catheter might have liberated the few red cells which were present; hence, when the menses had ceased, the parts were cleansed and the urine again collected and examined. The result was the same.

The character of the urinary secretion, together with the absence of fever and the good general condition, appeared to exclude suppurative affections, tuberculosis, malignant tumors, and acute and chronic nephritis.

There were no evidences of disease of the spine or of adjacent organs.

There remained for consideration calculi without infection, "idiopathic" nephralgia, and nephralgia due to irritating substances in the urine.

In favor of calculi was the increase of pain, tenderness, and blood in the urine on motion, jolting of the body, or percussion of the lumbar region, with decrease of these symptoms during rest in bed. The presence of hyaline casts is considered a valuable confirmatory sign by Muser.

Against the presence of stone was the limited number of blood discs and casts, and the fact that the patient had never passed any gravel.

As the blood might have been due to the presence of calcium-oxalate crystals, nitrohydrochloric acid was administered until they disappeared; but the pain on exercise, the tenderness, and blood remained.

The diagnosis seemed, accordingly, to lie between so-called idiopathic nephralgia and nephrolithiasis. The patient was informed that, although a positive diagnosis could not be made, an exploratory incision was indicated, owing to the severity and long standing of the symptoms, and their stubborn resistance to medication. At the operation, in which the kidney was freely incised along its convex border and reunited by catgut sutures, nothing was found except an undue movability of the organ. Nephrectomy was done, and

SURGICAL DISEASES OF THE KIDNEYS:*

CASES ILLUSTRATING
SOME POINTS IN DIAGNOSIS AND TREATMENT.

By LEONARD FREEMAN, M. D.,
Professor of Surgery, Gross Medical College; Surgeon to the Larimer County Hospital, and to St. Anthony's Hospital, Denver, Col.

Renal surgery is of such recent origin that many physicians have not realized its possibilities, owing, perhaps, to the spirit of conservatism, which renders progress slower but safer. Ten or fifteen years ago it was considered dangerous and daring to cut into the substance of a kidney or to remove it, but these operations are now done every day with satisfactory results and with but little danger.

As in most other branches of surgery, extremely radical measures were at first employed, which were followed by more conservative ones. Not long since it was the rule to at once remove diseased kidneys, irrespective of what the affection might be; even movable kidneys were often treated in this manner. At the present time nephrectomy is resorted to in extreme cases only, and then more often as a secondary than as a primary operation.

The tendency of modern surgery is toward early operations, renal surgery being no exception to the rule. Unfortunately, there are still many physicians who, through timidity or lack of information, permit their

* Read before the Colorado State Medical Society, June, 1889.
union by first intention, without drainage, was obtained. Complete recovery from symptoms ensued after the lapse of some weeks.

This case illustrates the difficulties in diagnosis sometimes encountered in affections of the renal organs, and emphasizes the fact that time, patience, and minute investigation are often required, and even then failure may result. Attention is also called to the observation that blood in the urine may be due to movable kidney as well as to such conditions as nephrolithiasis, tumor, tuberculosis, irritating crystals, etc.

In this connection I desire to mention a feature of movable kidney occurring in this case which I have not seen stated elsewhere—the absence of symptoms during pregnancy, due, perhaps, to the support furnished by an enlarged uterus.

**CASE II.**—A strong, healthy man of about forty years, with symptoms similar to those of the previous case. The urine was acid, contained a few red blood-corpuscles, some hyaline casts, and an abundance of urates, and was of high specific gravity. A movable kidney was suspected, although, the abdominal walls being thick, nothing could be discovered on palpation; but treatment directed to the diminution of acidity and specific gravity of the urine cleared up the symptoms in a few days.

This case serves to remind us that in nephralgic conditions internal treatment should be tried before operation is resorted to; but it should not be lost sight of that exploratory incisions often give relief in bad cases of nephralgia where medicines fail.

**CASE III.**—A movable kidney in a well-developed and well-nourished young woman of twenty-five years. In addition to the ordinary symptoms, the urine contained an immense number of hyaline, granular, and epithelial casts, without albumin. A nephrohraphy was done, union by first intention being obtained. Following the operation the number of casts rapidly diminished until they almost if not quite disappeared. The other symptoms were also recovered from.

Is it possible that serious danger to the kidney was here averted by timely operative intervention?

**CASE IV.**—A woman of about thirty-five years, with right movable kidney, which descended as far as the crest of the ilium. A severe and persistent sciatica existed, which had resisted all treatment, and which incapacitated the patient for work. This immediately disappeared on the performance of nephrohraphy, and has not returned at the end of more than eight months, except occasionally as a slight soreness at the sciatic notch.

**CASE V.**—A well-nourished woman, between thirty and thirty-five years, fell from a wagon some fourteen years ago, alighting on her back. Shortly after this she experienced, whenever she moved about, severe dragging pains in the pelvis, back, and thighs, and irritation of the bladder. The symptoms disappeared after a rest in bed. Being forced to give up all her duties, she consulted a gynecologist, who promptly removed the uterus, tubes, and ovaries; but the old symptoms continued as before.

When the patient came under my care, the pelvis being empty, I examined the kidneys and found them both extremely movable. After a rest in the recumbent position, the application of an elastic bandage about the waist, with properly adjusted pads, caused the complete disappearance of the annoying pains.

The patient, however, not liking the belt, insisted upon an operation. Double nephrohraphy was accordingly performed, with gratifying results. A stitch abscess, however, resulted in a temporary sinus.

This case would seem to indicate that before resorting to serious and mutilating pelvic operations it would be wise at times to examine the kidneys. It also shows how easy it is to refer kidney symptoms to the pelvic organs.

**CASE VI.**—A man, about thirty years of age, well developed and in good health, had noticed all his life a tumor in the region of the left inguinal canal. This was supposed to be an undescended testis. There was no testicle in the scrotum on that side, and the tumor was of the size and shape of a large testicle, and gave rise to a painfully sickening sensation when pressed upon. At irregular intervals inflammation and swelling took place, giving rise to much suffering and disability. The urine was normal.

At the operation it was only after the most careful scrutiny that what was supposed to be a testicle was found to be an undeveloped kidney lying in the inguinal canal. An atrophied testicle was lodged beneath the kidney, and a hernial sac lay by its side. The kidney was filled with a black fluid, and its ureter was a mere fibrous cord resembling a vas deferens. A radical operation for hernia, castration, and nephrectomy were simultaneously performed, an uneventful recovery resulting.

**CASE VII.**—A boy, twelve years old, fell fifteen feet from a tree, striking his left side on a projecting root. He was collapsed for a time, suffering great pain and passing blood in the urine. In a few hours the temperature went to 103° F. The pulse became rapid, and a tense, tender swelling appeared in the left side above the ilium. No blood was noticed in the movements from the bowels, but blood had not been looked for. On the third day, the high pulse and temperature continuing, an exploratory incision was determined upon, especially as an extraperitoneal rupture of the colon was suspected in addition to injury to the kidney. The kidney was found torn almost in two, and surrounded with a large quantity of fluid blood and urine. The bowel was uninjured. Recovery, after drainage, was rapid and complete.

The propriety of operation in injuries of the kidneys presenting such marked symptoms will not be questioned. It enables us to check hemorrhage, forestall the formation of an abscess, and save the peritoneal cavity from possible contamination.

**CASE VIII.**—A man, about thirty-five, was shot in the left side with a .45-caliber bullet, which passed downward through the lower portion of the pleural cavity, wounded the kidney, and passed out to the left of the lumbar spine. There being much extravasation of blood and urine, an incision was made down to the kidney for purposes of drainage. Infection, which had already taken place, was soon pronounced, and at the
end of several weeks secondary hemorrhage set in. This was at first easily controlled by packing, but it suddenly became so profuse as to almost exsanguinate the patient. As a desperate resort, a nephrectomy was rapidly done without anesthesia, the renal pedicle being secured by clamps, which were left in place. The operation required but a few moments. The patient rallied under the liberal use of saline solution, and ultimately recovered. For a long time a fistula remained through which urine frequently regurgitated from the bladder when the individual was in a recumbent position.

From general considerations, and from the course of this particular case, I am inclined to believe the safe procedure in secondary renal hemorrhage to be a prompt nephrectomy. The unusual feature of regurgitation of urine from the bladder is worth noting.

CASE IX.—An emaciated old man of about seventy years suffered from profuse and constant renal hemorrhage, for which no cause could be detected. His condition was such as to discourage operative intervention, even if anything could have been found to operate for. He had been strongly addicted to the eating of crude opium. The drug had been suddenly taken from him just before the hemorrhage began. Death from exsanguination shortly resulted. At the autopsy, made by Dr. W. N. Beggs, of Denver, no cause for the bleeding was discovered. The kidneys were apparently normal, except for some moderate fibrous changes which accompany age.

Was the excessive hemorrhage connected with the opium habit, or was it due to the mild interstitial nephritis?

CASE X.—Perinephritic abscess, originating without apparent cause in a young man of about thirty years. Pain and tenderness were at first of such an uncertain character, and the general symptoms so pronounced, that the case was treated as typhoid fever for three weeks by the physician in charge. At the end of this time attention was strongly directed to the back, but even then only the slightest possible fullness could be detected in the left lumbar region. Incision revealed a large abscess surrounding the lower part of the kidney, but not connected with it. Recovery.

CASE XI.—A man of over sixty years strained himself severely on the right side of the abdomen, producing an acute inguinal hernia, to which a truss was applied. After a time fever developed, which continued many weeks. When examined, the temperature was 103° F. The right thigh was flexed on the abdomen, and the iliac fossa moderately tender, although no swelling could be felt. A peculiar soft, emphysematous tumor existed near the external inguinal ring, which crackled beneath the fingers and could be reduced within the abdomen, but which lacked the usual characteristics of a hernia. Prolonged observation failing to throw much light on the nature of the case, an incision was made above Poupart's ligament and the peritoneum turned up. A large retroperitoneal abscess was found, extending down from the region of the kidney, and with a fingerlike prolongation alongside the inguinal canal. The cavity contained a great amount of offensive gas and comparatively little pus, although there was no connection with the bowel. The peculiar tumor men-

tioned above was due to the presence of this gas. An inguinal hernia existed also. A lumbar incision was made for the sake of better drainage. The patient reacted well from the operation, but died from the effects of a heavy fall from his bed during the night.

In such cases the painful contraction of the thigh, together with fever, should call attention to the probable existence of an abscess closely connected with the ilio-psoas muscle.

CASE XII.—A man between thirty and thirty-five had suffered for several years with recurring abscesses of the prostate gland, following a perineal operation for stone. There was great irritability of the bladder, which continued, without apparent cause, after the prostatic trouble had been relieved. There was also moderate fever, together with increasing debility and loss of weight. Although it was known that some suppurative disease of the right kidney existed, there was not sufficient pain and tenderness to call marked attention to the organ. No tumor could be felt; but the muscles were too rigid to permit a satisfactory examination. It was finally decided, however, to cut down upon the kidney. Five abscesses were encountered, containing several pints of pus. The kidney, which was incised and drained, was found pushed over to the median line. The abscesses were not connected, and were discovered one after the other by means of an exploring syringe. The bladder symptoms at once disappeared and the patient made an excellent recovery, although a small purulent sinus remained.

This case calls attention to the fact, which is not widely enough appreciated, that irritability of the bladder may be due to affections of the kidneys. The illusion may be so great that the bladder has been frequently considered to be the seat of the trouble, and treated accordingly.

In opening purulent collections about the kidney, we should always satisfy ourselves that more than one abscess does not exist.

Where there is reason to believe, from examination of the urine, that the kidney is involved in the suppurative process, I believe it is wise, when possible, to open and drain that organ at the time of operating, although some advice against this course.

CASE XIII.—A woman, perhaps forty years of age, had suffered for years with pain and other symptoms of such character that ovarian and bladder trouble had been diagnosed. Finally, an enlarged movable kidney was discovered, and a nephrectomy revealed several abscess cavities containing three calculi of moderate size. Drainage was followed by complete recovery. Much damage to the kidney and great suffering might have been prevented by earlier operation.

CASES XIV and XV were cases of suppurative nephritis (possibly pyelonephritis) following parturition. The urine was cloudy with pus in suspension; and there were pain and tenderness in the right lumbar region. A free incision revealed in each case an enlarged and softened kidney, with numerous foci of infection scattered throughout its substance. Drainage and recovery.

These successful cases indicate that even in so-called suppurative nephritis, with disseminated inflammatory
feci, nephrotomy, instead of nephrectomy, may result in cure.

Case XVI.—Congenital hydronephrosis in a girl of twelve years. The tumor was enormous, occupying the entire right side of the abdomen, and extending several inches beyond the median line. At intervals the swelling became more tense, accompanied by pain, vomiting, headache, diarrhea, etc. Ordinarily there was but little discomfort. On one occasion, at least, a tumor the size of a fist had appeared upon the left side.

The right kidney, exposed through a lumbar incision, was distended into a thin layer, but the hydronephrotic sac was principally from the pelvis. Although it seemed scarcely possible that any secreting substance remained, the kidney was not removed, because of the probable unsoundness of the other organ, and because of the difficulty attending the removal of so large a cyst. The kidney was, however, swung around on its axis, in order to correct, if possible, a hypothetical faulty insertion of the ureter. In the course of two or three days an abundance of urine was flowing from the lumbar incision.

This case demonstrates that when the renal substance appears to be totally destroyed it may still be capable of performing its functions.

I believe it to be preferable, where the soundness of the other kidney is uncertain, to refrain from making a primary nephrectomy. Later, when the hydronephrotic sac has contracted, if a fistula remain, a plastic operation may be attempted upon the ureter. If this should fail, a nephrectomy may perhaps be done.

It should be kept in view, however, that a live patient with a urinary fistula is much preferable to a dead patient. When last heard from the fistula in this case was discharging very little.

Cases XVII and XVIII.—During the past year I have encountered one case of pyelitis and one of suppurrative nephritis, due to the colon bacillus, both following fulminating cases of appendicitis with localized purulent peritonitis. No operation on the kidneys was made in either instance. The case of pyelitis recovered, but the suppurrative nephritis terminated fatally at the end of seven weeks.

Cases XIX and XX.—I have also seen two cases of pyelonephritis, due to the colon bacillus, arising from catheterization of ureteric bladder following distention. Both terminated fatally, with symptoms of general sepsis. Physicians should be on the lookout for these colon-bacillus infections and meet them promptly with urotropin or salol.

Case XXI.—A well-built, healthy looking girl of eighteen years. Since she was four or five years of age she had complained of pain and tenderness in the region of the right kidney. At first the attacks of pain were rather infrequent, perhaps once a month, or not so often. They gradually became more frequent, until during the last five months constant distress has been present. At the time of examination there was much tenderness over the kidney, both anteriorly and posteriorly, although the pain had shifted to a point just internal to the anterior superior spine of the ilium. No history of renal colic or the passage of gravel. The right kidney seemed to be somewhat loose. Jarring the body or pounding upon the lumbar region produced sharp pain.

An examination of the urine disclosed cystine crystals in considerable quantity, together with a moderate number of leucocytes, a few red blood-corpuscles, and many epithelial cells. There were no casts. The urine was neutral, with a normal specific gravity, and contained no albumin.

The diagnosis of cystinuria was made, and it was considered probable that a calculus existed in the right kidney, although the symptoms might be attributed to a movable kidney, or possibly to the presence of the sharp cystine crystals.

While the patient was under observation she fell down a flight of stairs, striking heavily on the affected side. At once the pain, which had existed steadily for so many months, absolutely disappeared, and at the end of a week, when I lost sight of the case, had not reappeared. Tenderness also rapidly subsided. This abrupt cessation of symptoms would seem to point to the existence of a stone, which suddenly, under the influence of the trauma, shifted its position, and ceased to be a source of irritation.

Cystinuria is such an extremely rare disease that Delafield, in the Twentieth Century Practice, asserts that but seventy-five cases have been reported. The etiology is involved in obscurity, and no reliable treatment is known. Dr. J. N. Hall, who saw the case with me, and independently arrived at conclusions similar to my own, developed the interesting fact that the patient could not wear a silver ring during the last five months, owing to its turning black almost as rapidly as it was polished. The explanation of this phenomenon undoubtedly is that those affected with cystinuria exude a certain amount of sulphur through the skin. Cystine itself, as is well known, contains about twenty-six per cent. of sulphur.

The patient was told that if her annoying symptoms returned an exploratory lumbar incision might be advisable.

THE EFFECT OF ATMOSPHERIC CHANGES ON THE HEARING IN CHRONIC CATARRHAL OTITIS MEDIA.*

By SEYMOUR OPPENHEIMER, M. D.,
ATTENDING LARYNGOLOGIST TO BELLETUCE HOSPITAL, OUTDOOR DEPARTMENT; ATTENDING LARYNGOLOGIST TO UNIVERSITY MEDICAL COLLEGE DISPENSARY; SENIOR ASSISTANT TO THE CHAIR OF LARYNGOLOGY, UNIVERSITY MEDICAL COLLEGE.

It appears to be commonly accepted among the laity, and to a certain extent among physicians, that audition, especially when the auditory apparatus is the seat of a morbid process, is unfavorably influenced by atmospheric changes. With the view of ascertaining the detrimental action of barometric and thermal changes upon the already impaired hearing in catarrhal deafness, fifty consecutive cases of chronic sclerosis of the middle ear were studied over a considerable period of

* Read before the New York County Medical Association, March 20, 1899.
time, and the usual tests were used to determine the variations in the hearing under different atmospheric conditions.

The normal ear is practically uninfluenced by changes in the weather, excepting that, depending upon the amount of atmospheric moisture, the transmission of sonorous vibrations from a considerable distance is more or less clearly appreciated. This follows well-known physical laws, and when clearly understood enables one to better appreciate the effect of the same atmospheric conditions upon the diseased ear. For the same reason the intimate relationship of the tympanic cavity to the nasopharynx and other portions of the upper respiratory tract must be taken into consideration. The auditory end organ, for it may be so considered, is but a specialized diverticulum of the respiratory areas, and partakes in all respects except in its special function of the histological characteristics of the former. The mucous membrane of the tympanic cavity is but an extension of that of the nasopharynx, and the physical conditions acting upon the mucosa of the latter affect in the same way that of the middle ear. This is not only anatomically demonstrated in health, but becomes especially marked in catarrhal conditions of the mucous membrane of the nose and pharynx, it being an almost constant rule to find diminution of auditory acuity following long-continued catarrh of the nose or throat.

The vast majority of cases of suppuration of the middle ear result from extension of inflammatory nasopharyngeal changes through the continuous mucous membrane of the Eustachian tube and subsequent infection through the same route. It is decidedly uncommon to observe a case of chronic sclerosis of the tympanum without evidences of nasopharyngeal catarrh antedating the aural affection. As a final evidence of the existence of this intimate connection, little can be done toward the improvement or restoration of the impaired hearing until the other portions of the upper respiratory tract are restored to an approximately normal condition. Therefore it becomes necessary for us to regard catarrhal states of the tympanum and catarrh of the nasopharynx as varying manifestations of the same disease, its phenomena varying only by the interference with the functions of the special organ involved, both being subjected to the same atmospheric influences.

As a rule, all the conditions favorable to the production of morbid changes of the respiratory and tympanic mucous membrane are dependent upon a lowering of the general vitality, mainly due to the continuous action of unfavorable climatic or hygienic surroundings. This is of such common experience that it is not necessary to cite individual cases, but it was plainly brought out in the cases studied that in those individuals in whom the hearing was most adversely affected in unfavorable weather a lowering of the general health was present at such times. And when one is run down by disease or other causes, such as fatigue, the susceptibility to temperature and barometric changes is greatly enhanced. Unfavorable climatic conditions also, especially if their action on the individual is repeated or constant, produce a state of more or less systemic depression, which, in turn, reacting upon the mucous membranes, render them less able to resist the morbid causes of catarrhal inflammation.

Primarily the changes in the atmospheric tension cause hyperemia of the mucous membranes by chilling of the body surface, when the dermal covering is not sufficiently prepared for the action of cold or excessive humidity. This is true in a general sense of the entire mucous membrane system, and especially that of the respiratory tract, but locally the action of lowered barometric pressure may be well observed in the nasal chambers, especially in an individual affected with catarrhal rhinitis. Under these conditions marked congestion and swelling, with increased secretion, result, the turbinal cavernous tissue becomes enlarged, and nasal respiration is decidedly diminished. In bright, clear weather, with a normal or rising barometer, capillary congestion does not take place, and there is no obstruction to the passage of air through the nares.

Besides the relation borne by the auditory apparatus to the upper respiratory tract, the tympanic cavity, in its relation to the normal or varied atmospheric pressure, is related indirectly to the various pneumatic spaces of the head. Changes in the normal atmospheric pressure act the same on the cavities containing air (the antrum of Highmore, etc.) as they do on the tympanum, the pressure exerted in these internal cavities being the same as the pressure exerted upon the external surface of the body. Practically, however, the pressure in the other head cavities does not vary, while the air in the tympanum changes to a certain extent with every act of swallowing, this portion of the pneumatic system being but temporarily in direct communication with the outer air. Upon this fact depends the restoration of hearing in certain cases of beginning catarrhal otitis. By the opening of the Eustachian tube the rarefied air in the tympanum is replaced with the normal pressure air. Diminution of the intratympanic pressure, even to a limited extent, seriously interferes with the transmission of sound waves.

For the reason that all the cases presented well-marked evidences of sclerotic changes of the tympanic tissues, the term chronic sclerotic otitis media is here used as a characteristic designation in preference to the more common one of catarrhal deafness. In all these cases sclerosis and atrophy represent but later stages of a previous cell proliferation, and a complete understanding of the pathological changes occurring in the tympanum is necessary to comprehend the deleterious effect produced on auditory perception by atmospheric influences. The pathogenesis is constantly and slowly
progressing from the initial catarrhal inflammation, with its cellular increase, exudation, and overgrowth, to finally sclerosis and contraction, and ultimately atrophy of the mucous lining. When this late stage is reached the blood supply is much limited, the tissues are firm and contracted, and the Eustachian tube and nasopharynx in the majority of cases partake in the more or less general condition. In the pure atrophic stage atmospheric changes in no way affect the greatly diminished hearing capacity; while in the sclerotic stage, where examination of the tympanic cavity shows patches of beginning or well-marked atrophy along side of areas of cell proliferation or hyperemia, atmospheric changes invariably impair for the time being the already affected audition.

The degree of hearing impairment is influenced in proportion to the location of hyperplastic tissue situated at or in immediate proximity to the path of the transmission of sound waves. Should sclerotic or atrophic changes exist in practically all portions of the tympanum, except a small area of proliferating connective tissue situated at the point of articulation of the foot plate of the stapes with the oval window, any slight change in the barometric pressure would be immediately appreciated and impairment of hearing rapidly ensue from the additional succulence of this mass of tissue and the resultant interference with the transmission of sonorous vibrations from the ossicular chain to the important structures of the perceptive apparatus. Further, as a result of repeated acute attacks of catarrhal inflammation of the respiratory mucosa, resulting from atmospheric alterations, Eustachian salpingitis is of frequent occurrence, and from the consequent occlusion of the Eustachian tube stagnation of the air in the tympanum results; this air, originally of the same pressure as the surrounding atmosphere, is to a great extent absorbed by the blood-vessels and becomes rarefied. The usual pressure is then removed from the capillaries and they become engorged with blood, and exudation of serum takes place, greatly interfering with the hearing. The hearing is also influenced through atmospheric changes in other ways than this; such as the production of an acute myringitis superadded to the already existing chronic process, and occasionally acute inflammation of the tympanic mucosa may result and produce impairment of audition in the same manner.

In all, fifty cases were under observation, and of these there were thirty-one females and nineteen males. As is well known, females are usually more susceptible to the ill effects of variable weather than males, especially as they are not, as a general rule, exposed as much to the elements as are the latter. Sex, however, bore no relation to the effect of barometric and thermal changes upon the hearing, the proportionate majority of those stating that the hearing was more impaired in damp weather being males. The youngest patient was nine years old, while the eldest was eighty-three. A careful analysis showed that, although the hearing ability was less in those of advanced years than in the younger patients, yet, all things being equal, the age of the individual was in no way a factor concerning the relation of the atmospheric variations to the impaired hearing.

The duration of time since the individual's attention was first attracted to the impaired hearing varied greatly, and from the insidious nature of this form of otitis many of the patients could not state the time when the impaired audition was first noticed. Of these, there were nineteen patients, and all stated that the aural affection had existed for at least two years, but other than this no definite data as regarded the duration could be obtained. In ten the disease had existed for a year; in eleven, between one and five years; in two, between five and ten years; in three, between ten and fifteen years; in three, between fifteen and twenty years, and in the remaining two the affection had existed between twenty and thirty years. The duration of time intervening from the appearance of gradual impairment of hearing to the time when the patients were first seen varied considerably, as usually morbid changes in the tympanum are fairly well advanced before the impairment of hearing is noticed by the patient. A number of the cases bore evidence to this point; one, for instance, as a typical example, stated that the hearing became impaired but one week before he was first seen, but examination showed that the disease had existed for several years, and the impairment of the auditory function had undoubtedly existed for a considerable time, but attention was only directed to it by an attack of coryza caused by sudden change in the weather.

The duration of the affection per se bore no relation to the increased impairment of hearing under unfavorable atmospheric changes, this point alone depending upon two factors: First, the amount and location of hyperplastic tissue in the tympanic cavity, and, secondly, the condition of the nasopharynx and Eustachian tubes. Of the first factor, the location of the hypertrophied tissue has been referred to, and requires no further consideration here; the amount of new tissue or cellular proliferation is also an important factor in determining the influence of atmospheric changes upon audition in the specific case. Of the fifty cases, eleven presented every evidence of a general atrophic condition of the tympanum, and in all these the hearing was greatly impaired both for aerial and bone conduction; four of these stated that some time in the past the hearing was worse on rainy or damp days, but not to any marked extent, while in the remainder atmospheric conditions had no influence at all. At the time the cases were examined, however, all gave evidence that barometric changes were entirely negative.

Twenty-one cases presented at the same time various phases of the pathological changes incident to catarrhal otitis, the examination disclosing that the atrophic condition was not as well marked as were the
sclerotic and hyperplastic changes. All of these were influenced by thermic and barometric changes, varying in degree of the impairment of audition with the individual case; while in the remaining eighteen the hyperplastic condition predominated and the hearing was markedly diminished during long-continued spells of damp, rainy weather, or when there were sudden atmospheric changes.

In this affection especially the three morbid stages mentioned do not always follow each other in sequence; many are sclerotic or atrophic from the commencement, while in others areas of hyperplasia may remain for a number of years and shrinking and absorbing changes not take place till after long periods of time. It will be seen, therefore, that the susceptibility of the affected ear to adverse weather conditions depends to a great extent upon the special pathological condition present and not upon the duration of time the affection has existed.

Attention was not especially paid to the influence exerted by the upper respiratory tract; but, independent of the aural pathogenesis, it was found that thirty-two of the cases complained of nasal obstruction, especially marked in rainy weather, and when this occurred the hearing was more diminished than when the turbinal swelling did not exist and when the nares were free. Whether one or both ears were affected was of no consequence at all. In thirty-nine cases both were involved; in seven, the right only, while in the remaining four the affection was limited to the left side. The degree of hearing may fluctuate from day to day, dependent upon the changes in the weather, and frequently, as a result of the catarrhal salpingitis usually present, there is an associated sense of fullness in the ears, referable to the Eustachian obstruction from the barometric changes.

Three factors in the climatic conditions exert a greater or less extent their influence upon the aural tissues in morbid changes of the tympanum; these are the humidity, barometric pressure, and temperature. Of minor importance are the electrical and other phenomena associated to a much less degree with the three prominent factors. The action of barometric pressure and humidity has been considered, while the effect of purely temperature changes is most difficult of explanation, but, so far as can be seen, practically exerts little influence. Generally, however, patients with catarrhal deafness will state that they are worse in the winter months, and during the heated term of summer the symptom-complex, and especially the deafness, is much less prominent. In all probability it is not the cold of winter that exerts a more deleterious action upon the ear than the higher temperature of summer, but the explanation seemingly lies in the excessive dampness of the winter months and the consequent tendency to the production of catarrhal changes of the respiratory and aural mucous membranes.

It may be here pointed out that catarrhal affections are most frequent in the transitional periods of autumn, and especially in the spring, during which times sudden alternations of cold, heat, dampness, and moisture become unduly exaggerated. The deleterious effects of climatic conditions upon the auditory apparatus depend therefore not to such an extent upon the yearly range of temperature, humidity, and pressure as upon the suddenness with which these conditions are apt to vary in a given period of time. For this reason catarrhal otitis is most common in localities where sudden changes occur in varying rapidity.

Conclusions.—1. The hearing in at least seventy per cent. of cases with chronic catarrhal deafness becomes worse under adverse weather conditions.

2. The degree of impairment of audition, as influenced by atmospheric changes, is determined to a great extent by the location and character of the pathological process in the tympanic cavity.

3. The morbid alterations most susceptible to barometric variations are those of hyperplasia.

4. In purely atrophic changes in the middle ear weather variations have little or no effect upon the auditory function.

5. Atmospheric influences also impair the hearing by unfavorably affecting catarrhal processes of the upper respiratory tract and Eustachian tube.

6. All things being equal, the impaired audition in chronic catarrhal otitis is diminished more (under unfavorable weather influences) in those whose general health is below par than in those otherwise healthy.

706 Madison Avenue,

A CLINICAL NOTE ON THE CONNECTION BETWEEN ASTHMA AND ECZEMA.

By H. NEVILLE TAYLOR,

M. A. CAMB.; M. A., N. D. DUBLIN; L. R. C. P. EDIN.; L. S. A. LOND., ETC.; CIVIL SURGEON, ARMY MEDICAL STAFF;
LATE ASSISTANT TO PHYSICIAN TO OUT-PATIENTS, MIDDLESEX HOSPITAL, LONDON, ENGLAND.

That there is some close connection between eczema and asthma is admitted by most authorities, and the following case, in addition to many already noted, points to the fact that whatever the condition of the bronchial mucosa is—whether catarrhal or erythematos— it is in close sympathy with that superficial dermatitis we term eczema.

The patient was a boy, aged eight years, of a somewhat strumous aspect. His mother suffered from asthma, but there is no history obtainable of any other relation having suffered from this complaint, or from gout, rheumatism, or any neurotic trouble. The patient himself, however, had some epileptiform convulsions when a baby, though his teeth show no "pitting"; he has had neither measles nor whooping-cough, and there is no evidence of any naso-pharyngeal adenoid growths.
His bowels are regular and his appetite is good. His one brother, younger, is up to the present quite healthy. At the age of six the patient had a severe attack of eczema, which, though under treatment, showed for six months no signs of improvement; the dermatitis then began to gradually disappear.

During the next year, however, he had another attack, so severe that his mother states that he became "almost blind"; while this second attack was clearing up he had his first asthmatic seizure. Then for a few months he suffered from asthma and eczema, the attacks being sometimes concurrent, sometimes definitely alternating, sometimes overlapping each other, the patient at no time being quite free from either.

Latterly, however, he has had intermissions of four to five weeks in the asthmatic fits, but his skin has been in a state of more or less chronic eczema or xerodermia.

He came under my care for a recent exacerbation of the dermatitis, the flexures of his hands, wrists, arms, and legs, his face and trunk being in a pitiable condition from the intense irritation and subsequent scratching and pus inoculation. After a few weeks' treatment this condition was becoming materially ameliorated and his skin resuming its usual xerodermatous condition, when he presented himself one morning with a typical asthmatic attack. I then elicited from his mother the above history.

Dr. Gee, in his Lumleian Lecture, 1899, cites two interesting cases of a similar nature—the one a girl, aged eleven, had, when a baby, eczema, but from the age of two had suffered from asthma; a younger brother had a like history. On the father's side there was evidence of gout and eczema; on the mother's, of an asthmatic tendency; the other, a boy of two and a half years, suffered from the age of six to twelve months from eczema, which then cleared up and he became asthmatic.

It has been argued, because of the sudden development of the symptoms of asthma and their subsequent rapid cessation, that the disease must be of the nature of some spasmodic contraction of the bronchial muscles, but when one remembers how quickly the vasomotor disturbance producing an urticarial "wheal" may occur and subside, I do not think that we have sufficient reason for putting "out of court" the theory that asthma may be due to some sudden vascular engorgement or erythematous "blush" of the bronchial mucosa, though this very sudden rise and fall of the bronchial symptoms militates against the view held by some that asthma is really "eczema" of the bronchial tubes. Eczematous eruptions are unfortunately anything but of an evanescent nature.

Certain articles of diet, by producing gastric irritation, may cause an eczema or asthma, sometimes both simultaneously; and Morris points out that a person may take a chill which subsequently may develop not into a bronchial catarrh but into an attack of dermatitis, and he goes on to say that "both eczema and asthma are the response by the skin and respiratory mucous membrane, respectively, to some central or peripheral irritation to which both alike are exposed."

Brocq insists that the rapid disappearance of an eczematous eruption—a happy but too infrequent consummation—may lead to dangerous pulmonary congestion, though, according to the same authority, it is more usual in middle life that eczema alternates with visceral—pulmonary, cardiac, or cerebral—lesions.

The influence of gout and rheumatism as constitutional and predisposing causes of eczema is more in evidence in middle life, while the eczema of children is usually of the seborrhoeic type, starting from the head (Morris).

While the problem of the connection between eczema and asthma is still unsolved, we can only ask in Dr. Gee's words, "What is the bond which in so many cases connects the several diatheses of asthma, gout, and eczema?" But we can hope that one day a satisfactory answer will be given to a question of so much theoretical and practical interest.

THE TREATMENT OF FOLLICULAR AND SUPPURATIVE AMYGDALITIS AND THE ANGINA OF SCARLET FEVER BY THE INJECTION OF A SOLUTION OF CARBOLIC ACID.

By H. Judson Lipes, M. D., Instructor of Obstetrics, Albany Medical College, Albany, N. Y.

Heurnee, of Leipzig, first suggested the injection of a solution of carbolic acid in the treatment of the angina of scarlet fever, and the successful results obtained prompted others to try the same measure.

Professor Seitz, the director of the Children's Polyclinic at Munich, reports excellent effects by this treatment in scarlet fever, but did not find it of service in diphtheria.

Having been a frequent sufferer from follicular amygdalitis, the writer has used this method on himself after other remedies failed, and received such relief that he concluded to use the treatment in similar cases. The results have been fairly satisfactory.

The method of procedure is simple. Professor Seitz used a three-per-cent. solution of carbolic acid and injected a few drops into each tonsil at several points. A small syringe was used with a long needle having a shoulder about four millimetres from the point, to prevent too deep introduction and consequent injury to the larger vessels. After having used in several cases an ordinary hypodermic syringe with an extra long needle, we procured a special one. The shank and needle proper are together about six centimetres long and have the extremity turned at an angle of forty-five degrees, the elbow being about three millimetres from the point.
This form of needle permits the operator to inject the solution into the tonsils easily and safely, the elbow preventing too deep introduction. In children it was necessary, of course, to use a mouth gag and a tongue depressor.

The solution has varied in strength from one per cent. to four per cent. Cognizant of the fact that carbo-lie acid solutions, even as weak as one per cent., often produce serious gangrene in children, particularly of the extremities, when applied in poultices or otherwise, it was with some hesitation that even a one-per-cent. solution was used in the younger patients. No bad effects were noticed, however, probably on account of the great vascularity of the tonsils.

The results of this method of treatment are based upon nineteen cases—not enough, perhaps, to establish positively its merits, but the results have been satisfactory in proper cases, and therefore the remedy merits further trial.

The cases under observation in which this method was tried include five of scarlet fever, six of diphtheria, three of suppurrative, four of simple, and three of follicular amgyaldalitis. A brief résumé of the results obtained may perhaps be of interest. All but two cases were among children from eight months to fifteen years of age.

In cases of diphtheria no beneficial effects were observed, at least none that could be ascribed to the carbo-lie acid injections, since antitoxine was used immediately in all cases together with other appropriate treatment. In fact, I believe that this method may really be harmful in diphtheria, since it may destroy the combative influence of the staphylococci on the Klebs-Loeffler bacillus.

There was no doubt about the value of this procedure in the cases of scarlet fever. Immediate relief was obtained, with a prompt reduction of the fever and an improvement of the general condition. These cases occurred in girls of four, six, and seven years of age. In the youngest patient, the first one treated, a one-per-cent. solution was used, and in only one tonsil; and, as some relief and no bad effects were observed, a few hours later both tonsils were injected with a three-per-cent. solution. In the two other cases only a single injection was necessary, none of the cases being of a severe type.

The four cases of simple amgyaldalitis were seen in the early stages, and, as prompt abortive measures were tried in conjunction with the injections of carbo-lie acid, it is impossible to measure the exact value of the injections. All cases responded to the treatment quickly.

More positive results were obtained in follicular and suppurrative amgyaldalitis where the cases were seen sufficiently early. For example, in one case the left tonsil, which was the more inflamed, was treated. The relief was immediate, so that in a few hours the right tonsil, which was as yet but slightly inflamed, seemed to be much the worse. In another case where both tonsils were treated, the one which had become inflamed first was not benefited so much, the process having proceeded too far, but the condition of the inflammation of the other tonsil was aborted.

A prominent physician of this city presented himself for treatment, and, after informing him of the pleasant results which had been obtained, the injections were permitted. He had suffered from suppurrative amgyaldalitis several times previously. One tonsil alone was affected and the inflammatory process had but fairly begun. A three-per-cent. solution was used, and next day he informed me that although he had suffered some inconvenience from the apparent hypersemia of the tonsil after the anaesthetic effect of the acid had disappeared, the inflammation had subsided and the condition was greatly improved.

In children, amgyaldalitis occurs more frequently than is generally supposed, and, unless a physician examines the throats of all children systematically, many cases will escape notice. Gargles, sprays, and similar measures are not easy to employ in children, and can not be used in infants at all. With proper assistance, however, it is not difficult to use the injections.

No carbo-lie acid intoxication was observed, nor was there any sloughing of the tonsilar tissue, which was greatly feared in the younger children.

1184 Broadway.

Therapeutical Notes

Lactic Acid as a Remedy for Baldness.—Balzer (Semaine médicale, May 19th; Fortschritte der Medicin, September 20th) practises friction of the bald part daily with a thirty-per-cent. solution of lactic acid until the skin becomes inflamed. Then the treatment is suspended for a few days, and resumed when the inflammation has subsided. He reports that he has often observed a new growth of hair in the course of three weeks.

For Facial Neuralgia.—Riforma medica for July 1st ascribes the following to Boequillon-Limouisn:
R Butyl chloral hydrate, of each, 150 grains;
Alcohol, 300 "
Glycerin 1,800 "
Distilled water 1,800 "
M. Half a soupspoonful to be taken daily.

For Chronic Rheumatism.—Settimana medica for September 9th recommends euphorine in doses of from three to six grains. From two to four doses may be taken daily.

Acetylsalicylic Acid (Aspirin).—Wohlgemuth and Withauer (Therapeutische Monatshefte; Fortschritte der Medicin, September 6th) find this preparation less apt to produce gastric derangement than sodium salicylate. It is given in daily amounts of from sixty to seventy-five grains, on sugar or in water.
Pyrogallic Acid in the Treatment of Psoriasis.— Richter (Monatshefte für praktische Dermatologie; Deutsche Aerzte-Zeitung, September 15th) recommends the following formula:

B. Salicylic acid, each 3 parts; Ichthyol, 10 a

C. Pyrogallic acid, each 75 grains; Olive oil 100 "

D. Wool fat 100 "

M. The action of the pyrogallic acid is said to be much intensified by the presence of the salicylic acid and ichthyol, but the ointment does not irritate the eyes or stain the skin.

For Constipation.—Riforma medica for August 19th attributes the following to Lyon:

A. Aloe, of each 75 grains; Extract of rhubarb, 30 a

B. Alcoholic extract of nux vomica 100 "

M. Make twenty-four pills. One to be taken in the evening.

The Treatment of Acute Gonorrhoea.—P. Albarran (Revista de Medicina y de Cirugia Practicas, August 10th; Journal of the American Medical Association, October 7th) asserts that the failure of the usual methods of treating gonorrhoea is owing to the folds and crevices of the membrane lining the urethra, in which germs may lurk sheltered from the irrigations. He suggests, and has been very successful with, a method consisting of distending the urethra with air. He injects two cubic centimetres of pure ichthyol and three cubic centimetres of air with a ten-cubic-centimetre syringe inserted through a perforated cone, which serves to prevent the escape of the air, when held against the orifice for one to three minutes while the urethra is lightly massaged.

Syrup of Creosote.—Riforma medica for July 13th gives the following:

A. Pure beech creosote 75 grains; Pure glycerin 1,300 "

B. Syrup 13,725 "

M. A soupspoonful holding three hundred grains contains a grain and a half of creosote. From five to six soupspoonfuls to be taken daily, before meals.

Tropacocaine as a Dental Anæsthetic.—Dorn (Odontologische Blätter; Klinisch-therapeutische Wochenschrift, September 24th) gives the following as Vamossy’s formula:

A. Tropacocaine hydrochloride 3 parts; Sodium chloride 6 "

B. Distilled water 100 "

M. The solution is said not to need sterilizing and to keep indefinitely. Dorn has used it in more than three hundred cases of tooth extraction, and never witnessed any untoward effects.

Syrup of Guaiacol.—Riforma medica for July 13th gives the following formula:

A. Crystallized guaiacol 113 grains; Pure glycerin 1,388 "

B. Syrup 13,300 "

M. A soupspoonful (three hundred grains) represents two and a quarter grains of crystallized guaiacol. From five to six soupspoonfuls daily during meals.

NEW YORK MEDICAL JOURNAL.
A Weekly Review of Medicine.
Published by D. APPLETON AND COMPANY. Edited by FRANK F. FOSTER, M.D.

NEW YORK, SATURDAY, OCTOBER 21, 1899.

INTER-STATE RECIPROCITY IN GRANTING THE LICENSE TO PRACTISE.

In our issue for August 12th we spoke in commendation of a movement set on foot by the Wayne County (Michigan) Medical Society looking toward securing cooperation in various States in the establishment of as near an approach to uniformity of State license requirements as might seem attainable. At that time the society had intrusted its scheme to a committee consisting of Dr. George G. Gordon (president), Dr. E. B. Smith, Dr. F. D. Summers, Dr. E. H. Troy, and Dr. E. Amberg (secretary), which committee had sent a circular of inquiry to the proper authorities of each State and Territory.

The committee announce now that they have received, up to September 14th, answers from thirty-nine States and Territories, and that almost all these answers are favorable to the more important features of the undertaking—that is, they express an inclination to consider favorably the plan of entering into reciprocity with other States and Territories having practically the same requirements as their own, together with a willingness to cooperate in preparing a memorandum to serve as the basis of proposed legislation in the various States concerned. The committee add that the few unfavorable answers received were accompanied by explanations which warrant the hope that it is practicable to overcome certain difficulties which do not at present allow of a favorable reply. They report also that from other sources they have met with encouragement and their plan has received approval. In this connection, they are kind enough to mention our article.

We are glad to learn of the degree of success that has attended the committee’s efforts in this undertaking, and we feel like urging all medical societies that deal at all with such matters to give the Wayne County Medical Society as full a measure of support and cooperation as possible. No doubt there are difficulties in the way of absolute uniformity of requirements, but the limited and reasonable reciprocity that our Michigan brethren are seeking to secure seems to us feasible. It certainly is desirable. Events succeed each other
rapidly in these closing years of the nineteenth century, and the unhoped-for comes to pass almost before we have had time to realize what its fulfillment would mean. Let us, therefore, never despair of the consummation of a desired improvement.

THE CAUSES OF PYORRHEA ALVEOLARIS.

This common affection is generally known in this country as Riggs’s disease, though it was described by Fauchard so long ago as in 1728. Its pathogenesis has been the subject of considerable difference of opinion among dentists; some have held that it was of constitutional origin. Dr. William J. Younger, of Chicago, who has made a particular study of the disease, read his most recent paper on it before the New York Institute of Stomatology in April of this year, and the communication, together with the discussion on it, was published in the July number of the International Dental Journal.

Dr. Younger does not believe that the disease is of constitutional origin, although he grants—what is not at all inconsistent with his own theory—that perfect systemic health enables the individual to so resist its progress as to make its course a protracted one. But perfect health, he insists, does not confer immunity, and no constitutional vitiation will of itself produce the disease. He regards it as essentially bacterial, but not in its inception; the first step, he thinks, is traumatism. This traumatism, he says, is brought about by some insoluble foreign substance lodging in the fold of the gum that surrounds the neck of the tooth and leading to irritation that subsequently brings on an inflammatory action which extends to the alveolar process. Among these foreign substances, he mentions little grains of sand, seeds of berries, husks of oatmeal, minute flakes floating in beer, little fragments of the skin of fruit or its core, bristles from the toothbrush, and various forms of the detritus of food. As regards this point, we may suggest that toothbrush bristles may not only themselves become detached and lodge between the gum and the tooth, but also force into that recess particles which otherwise would hardly enter it. We regard the bristle toothbrush as unfit for use. One made of badger’s hair will answer every purpose, and, we think, can be trusted not to invade the sockets of the teeth. That abomination, the wooden toothpick, too, doubtless often leaves some of its frizzy fibres between the gum and the tooth, to lead to just the irritation that Dr. Younger regards as the starting-point of alveolar pyorrhea.

Dr. Younger feels quite certain that his investiga-
tions, conducted in conjunction with Dr. G. W. Cook, of Chicago, so far as the bacteriology was concerned, have led to the discovery of the specific organism of the disease, which he describes as a very short, round bacillus, slightly motile at the normal temperature of the body, but showing little movement at that of 70° F. It is a facultative aerobic, he says, growing when either exposed to the oxygen of the atmosphere or deprived of it, liquefying gelatin, and forming a brownish coating on agar-agar, in which medium it grows readily and freely. In blood serum it seems to take on a stronger growth, appears in chainlike forms, and after ten or twelve days apparently produces spores. It is not found along the alveolar edge of the tooth or in the collections of tartar at the gingival margins, but only in “the deep-seated pockets where the advance guard of the disease is progressing.” The periodontal membrane must suffer perforation. He thinks, before the bacillus can play its part in the progress of the disease. Dr. Younger’s conception of the pathogeny of pyorrhea alveolaris seems reasonable and well borne out by observation so far as it has yet gone, and we look to see him reporting data still further confirmatory of his views.

AN ENDEMIC OF NEURALGIA.

A remarkable observation is recorded by Dr. Wille, of Oberdorf (Münchener medicinische Wochenschrift, 1899, Nos. 33–35; Deutsche Medicinal-Zeitung, September 25th), that of the occurrence of a hundred and twelve cases of neuralgia between the 10th of August and the 10th of November, 1898, fifty of which occurred in his own practice, and the rest among his colleagues’ patients. The physicians of Oberdorf could not satisfy themselves that the outbreak had any connection with zoster, masked malaria, primary multiple neuritis, or influenza. The last-mentioned condition seems to us the most probable cause of the endemic, and it is difficult to see how it could be absolutely excluded. The author, indeed, has little to say of the exciting causes of the endemic, but gives considerable attention to the predisposing causes. As regards locality, he observed that the outbreak was severest where the ground was marshy. The weather seemed to have had no ascertainable influence. Women appeared to be attacked a little more commonly than men, in the proportion of fifty-seven to forty-three per cent., and more than half the cases occurred in persons between twenty and forty years old. As to the preponderance of the affection among women, the author speculates upon the periodically recurring function of menstruation and the
like, but somewhat unsatisfactorily, it seems to us. Only in seven cases was a neurasthenic diathesis apparently operative in inviting the attack.

An endemic of neuralgia is certainly notable. Occurring in such an old community as that of Oberdorf, it ought to be readily recognized as connected with malarial poisoning or not. Primary multiple neuritis, too, should admit of ready recognition, if it existed, and the same may be said of malarial poisoning, however masked. We are still inclined to hazard the suggestion that the endemic was one of the multiform expressions of influenza.

THE OVERWORKED MEDICAL STUDENT.

In our issue for September 16th we said that medical men were alive to the damage that was being done to youth by the forcing system in their education, and we added: "That fact makes it all the more disgraceful that our medical schools are among the most flagrant scenes of its execution." Our esteemed contemporary the Journal of the American Medical Association thinks we are in error. In its issue for September 30th it says: "The errors of the medical curricula—and they may be numerous enough in the present transition state of medical education—are not that they are too thorough and advanced. Up to date they have not been advanced enough. Nor do we want a low average in our profession, something above mediocrity should be the aim. The foolishness of 'forcing' has not yet revealed itself in American medical education." We should be sorry to have it thought that we deprecated the advance of medical education. What we had in mind was the cramping of the medical student's memory, a process that is burdensome and unnecessary. We try to stock him with knowledge, whereas the proper end of schooling is to teach the pupil how to study to the best advantage, so that he may eventually become wise as well as learned. To be a good mathematician, a man need not commit the table of logarithms to memory.

EPILEPTIC PRIAPISM.

Féré. (Médecine moderne, 1899, No. 10; Monatshefte für praktische Dermatologie, September 1st) relates the case of a boy, twelve years old, in whom epileptic seizures were for a time replaced by attacks of crythrospia and for another period by exceedingly painful erections. Both the convulsions and the priapism yielded to the bromide treatment. We do not gather from the account that the priapism was persistent, as is sometimes observed in leukocytoma, but we think an examination of the blood in this case would be of interest.

AN ALLEGED PREVENTIVE OF THE PLAGUE.

Mr. Shamsudin J. Sulemani, of Baroda, states in the Lancet for September 16th that for nearly a year free use has been made in Baroda of certain pills as a preventive of the plague. Each pill contains two grains of quinine, a quarter of a grain each of ipecac and camphor, and a quarter of a minim of carbolic acid. A pill is to be taken twice a day. The writer gives observations which convince him that these pills are very efficacious. We can only hope that he is not mistaken.

A NEW CONCEPTION OF TEETOTALISM.

Newspaper medicine seems to flourish even in Greece. Dr. Achilles Rose translates as follows a paragraph that appeared in an Athenian daily paper recently: "It is known that the remedy against alcoholism employed in England and in the United States of America consists in the exclusive use of tea as a beverage. The followers of this system are called teetotalers [sic]. But the remedy is as pernicious as alcoholism itself. Many die after a few years of the tea habit, because they drink tea too frequently and take overdoses." The writer goes on to state that a certain American dramatic artist, mentioned by name, is the latest victim, and adds: "And now a crusade has been inaugurated in the United States against the use of tea."

THE TEXAS EMBARGO AGAINST NEW ORLEANS.

It is stated that the attorney-general of Louisiana has taken steps before the supreme court of the United States to obtain an injunction restraining the Texas authorities from enforcing an embargo against New Orleans on account of reports of the existence of yellow fever in that city. Without going into the merits of this particular case, we may express our decided conviction that the sooner the petty business of local quarantine is given up for good the better it will be for the entire country.

THE LOOMIS SANITARIUM.

We regret to learn of a destructive fire having occurred by which one of the buildings has been rendered at least uninhabitable for the time being, but we are glad to be able to add that it was not accompanied by loss of life.

"SICK" OR "ILL"?

Last Sunday the New York Times printed a letter which ended with the following statement: "Reliable sources tell us that 'sick' for ill has always been universal in Ireland, whence, like 'mad,' it was probably imported into this country, where, by a far-fetched method of reasoning, because the driver of a vehicle holds the reins the person who is driven is said to 'ride'—a word in England applied only to being carried on the back of some animal, two-legged or four-legged, more properly the latter." Are we to infer, then, that the phrase "in sickness and in health," got into the Book of Common Prayer by Irish machination, and that King James's translators were under Irish influence when they wrote "I was sick and ye visited me"?

INJURIES TO WOMEN IN COITON.

Under the heading Venus Cruenta Violans interdum Occidens (Monatschrift für Geburtshilfe und Gynäkologie, ix. 3; Deutsche Ärzte-Zeitung, September 15th), Neugebauer analyzes a hundred and fifty-seven cases of these injuries, including laceration of the perineum, of the sphincter ani, and of the posterior vault of the vagina with rupture of Douglas's pouch and
ZOSTER AND FACIAL PARALYSIS.

Nerves' trouble of an unusual extent and variety seems to have been connected with zoster in a case recorded by Grassmann (Deutsches Archiv für klinische Medicin, ix; Fortschritte der Medicin, September 27th). It began with sensory irritation in the region innervated by the right cervical plexus, and in a few days an herpetic rash appeared within that region, also in that of the third branch of the trigeminal and that of the facial. The rash disappeared in about eighteen days, leaving scars. During the existence of the rash there were symptoms of vasomotor irritation, such as swelling of the right cheek. On the eleventh day of the rash complete paralysis of the right facial nerve set in suddenly, and there were traces of it about six weeks later. After the subsidence of the rash there was excessive cutaneous sensitiveness in the area supplied by the cervical plexus, together with continued neuralgia.

DEGENERACY AND GENIUS.

According to the Medical News for October 7th, Lombroso has at last found a genius whom he can acquit of insanity. He has thus honored the memory of Goethe in a recent article in an Italian literary journal in which he refers to him as a normal, healthy, and sublime poet. This is an offset to his recent assertion in the Forum that Columbus was a paranoiac. The British Medical Journal for July 29th trenchantly traverses in a humorous manner Lombroso's evidences of insanity in Columbus and concludes: "Most people would doubtless prefer to be mad with Dante, Shakespeare, and Columbus to being sane with the ideal man of the criminal anthropologist, who writes like copper plate and has everything snug and symmetrical about him." We think so too.

ITEMS.

The Buffalo Academy of Medicine.—At the last meeting of the Section in Pathology, on Tuesday evening, the 17th inst., the following papers were presented for discussion: A Case of Poliomephalomyelitis in an Adult presenting the Clinical Symptoms of Landry's Paralysis and Terminating Fatally in Nine Days, by Dr. Dewitt H. Sherman; and The Significance of Chronic Rhinitis in Relation to Ocular Afections, by Dr. Edmund E. Blauw.

Marine-Hospital Service Health Reports.—The following cases of small-pox, yellow fever, cholera, and plague were reported to the surgeon-general during the week ending October 14, 1899:

**Small-pox—United States.**

- Jefferson County, Ark., Oct. 4, 29 cases.
- Pulaski County, Ark., Oct. 4, 6 cases.
- Butler County, Kan., Oct. 5, 5 cases.
- Cincinnati, Ohio, Sept. 30-Oct. 7, 3 cases.
- Cleveland, Ohio, Sept. 30-Oct. 7, 1 case.
- Dayton, Ohio, Sept. 30-Oct. 7, 2 cases.
- Allegheny, Pa., Sept. 30-Oct. 7, 3 cases.
- Memphis, Tenn., Sept. 30-Oct. 7, 2 cases.
- Portsmouth, Va., Sept. 30-Oct. 7, 2 cases.
- Seattle, Wash., Sept. 20-30, 1 case.

**Small-pox—Foreign.**

- Teneriffe, Canary Islands, Sept. 16-23, 2 deaths.
- Athens, Greece, Sept. 16-23, 7 cases.
- Bombay, India, Sept. 5, 12, 10 cases.
- Madras, India, Sept. 2-8, 1 death.
- Naples, Italy, Sept. 14-21, 3 deaths.
- Chihuahua, Mexico, Sept. 22-30, 7 deaths.
- City of Mexico, Mexico, Sept. 10-30, 21 cases.
- Cuacho, Mexico, Sept. 29, 25 cases.
- Midhat, Mexico, Sept. 29, 12 cases.
- Nueva Laredo, Mexico, July 1-Aug. 21, 3 cases.
- Orenza, Mexico, Sept. 29, 50 cases.
- Pilares, Mexico, Sept. 29, 13 cases.
- Progreso, Mexico, Oct. 7, 30 cases.
- San Antonio, Mexico, Sept. 29, 29 cases.
- San Felipe, Mexico, Sept. 29, 100 cases.
- San Francisco, Mexico, Sept. 29, 5 cases.
- San Juan, Mexico, Sept. 29, 100 cases.
- Sures, Mexico, Oct. 7, 40 cases.
- Vado de Piedras, Mexico, Sept. 29, 20 cases.
- Moscow, Russia, Sept. 3-16, 2 cases.
- Odessa, Russia, Sept. 16-26, 4 cases.
- St. Petersburg, Russia, Sept. 8-16, 1 case.
- Straits Settlements, Singapore, Aug. 20-26, 3 cases.

**Yellow Fever—United States.**

- Key West, Fla., Oct. 6-10, 137 cases, 4 deaths.
- New Orleans, La., Oct. 5-12, 8 cases, 2 deaths.

**Yellow Fever—Foreign.**

- Matanzas, Cuba, Oct. 3, 1 case (soldier).
- Nuevitas, Cuba, Sept. 9-16, 4 cases.
- Santiago, Cuba, Sept. 15-25, 4 cases.
- Vera Cruz, Mexico, Sept. 22-28, 9 cases.
- Victoria, Mexico, Oct. 6, Reported.
- Vicinity of city of Salvador, Salvador, Sept. 1, 11 cases, 1 death.

**Cholera.**

- Calcutta, India, Aug. 25-Sept. 2, 4 deaths.
- Karachi, India, Sept. 2-9, 1 case, 1 death.

**Plague.**

- Alexandria, Egypt, Sept. 17-24, 1 death.
- Maguio, Lorenzo Martinez, Sept. 22, Reported.
- Bombay, India, Sept. 5-12, 87 cases.
- Calcutta, India, Sept. 7-8, 54 cases.

**The St. Louis Medical Society.**—At the last regular meeting on Saturday evening, the 11th inst., Dr. I. N. Love read a paper entitled Appendicitis from the Medical Standpoint, which was discussed by Dr. E. S. Lenoine, Dr. P. A. French, Dr. M. P. Morell, and others.
ITEMS.  [N. Y. Med. Jour.]

Changes of Address.—Dr. B. M. Hawley, from Morristown, New Jersey, to No. 355 West Twenty-eighth Street, New York; Dr. Charles A. Jersey, to No. 203 West One Hundred and Thirty-first Street, New York; Dr. Walter Keene Wilkins, to No. 237 West Thirty-eighth Street, New York.

Army Intelligence.—Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from October 7 to October 14, 1899:

- Block, W. H., Acting Assistant Surgeon, United States Army, will proceed to Socorro, Cuba, for duty, relieving Macy, Robert C., Acting Assistant Surgeon, who will report at El Caney, Cuba, for station, relieving Lawason, George R., Acting Assistant Surgeon, United States Army, who, when thus relieved, will proceed to Havana.

- Boyd, Robert, Acting Assistant Surgeon, United States Army, is assigned to temporary duty at the General Hospital, Presidio of San Francisco, awaiting transportation to the Philippine Islands.

- Brown, Ira C., Major and Surgeon, United States Volunteers, will proceed to the Philippine Islands on the transport Valencia.

- Chmelicer, Joseph F., Acting Assistant Surgeon, United States Army, is assigned to duty as attending surgeon at Fort Winfield Scott, California, relieving Cohen, H. M., Acting Assistant Surgeon, United States Army, who will proceed to the Philippine Islands on the transport Valencia.

- Dean, Elmer A., First Lieutenant and Assistant Surgeon, United States Army, will report for duty as surgeon at camp of recruits and as medical inspector of regimental and recruit camps on the Presidio reservation, relieving Powell, Junius L., Major and Surgeon, United States Army, who will proceed to the Philippine Islands on the transport Zelandia.

- Ebert, R. G., Major and Surgeon, United States Army, accompanied by Schuelke, Julius A., Major and Surgeon, Thirty-fifth Infantry, will proceed to Portland, Oregon, and make a thorough sanitary inspection of the steamers Rio de Janeiro and Sikih, United States transports, upon their arrival at that city.

- Hartsuff, Albert, Lieutenant-Colonel and Deputy Surgeon-General, United States Army, will proceed to Fort Thomas, Kentucky, and inspect the camp of the Forty-eighth Infantry.

- Millhoff, Clarence B., First Lieutenant and Assistant Surgeon, United States Army, will report to the commanding general, Department of California, for assignment to duty with troops going to Manila.

- Perley, H. O., Major and Surgeon, United States Army, will proceed to the Philippine Islands on the transport Rio de Janeiro to join the hospital ship Relief.

- Stark, A. N., Captain and Assistant Surgeon, United States Army, will report to the commanding officer, Columbia Barracks, for duty at that post.

- Van Tuyl, W. R., Acting Assistant Surgeon, United States Army, is relieved from duty at the United States General Hospital, Presidio of San Francisco, and will report to the commanding officer of that post for duty at the camp of recruits, and as a member of the board of medical officers, vice Cattermole, Charles A., Acting Assistant Surgeon, United States Army, ordered to the Philippines.

Warren, Stanley S., Acting Assistant Surgeon, United States Army, will proceed to Fort Clark, Texas, for duty, relieving Woodson, Robert S., Captain and Assistant Surgeon, United States Army, who will proceed to San Francisco for duty.

The following officers are detailed to represent the Medical Department of the Army at the annual meeting of the American Public Health Association at Minneapolis, Minnesota, from October 31st to November 3d: Reed, Walter, Major and Surgeon, United States Army; Bradley, Alfred E., Major and Surgeon, United States Volunteers (Captain and Assistant Surgeon, United States Army).

Naval Intelligence.—Official List of Changes in the Medical Corps of the United States Navy for the Week ending October 13, 1899:

- Atlee, L. W., Surgeon. Detached from the Solace and resignation accepted.

- Bagg, C. P., Passed Assistant Surgeon. Detached from the Pensacola and ordered to the Solace.

- Hawke, J. A., Medical Inspector. Promoted to medical director.

- Lewis, D. O., Surgeon. Detached from the Mare Island Navy Yard and ordered to the Iowa.

- Lovering, P. A., Surgeon. Ordered to the Mare Island Navy Yard.

- Page, J. E., Passed Assistant Surgeon. Ordered to the Pensacola.

Siegfried, C. A., Medical Inspector. Detached from the torpedo station at Newport, Rhode Island, and ordered to continue in charge of the Naval Hospital, Coasters Harbor Island, Rhode Island.

Simons, M. H., Surgeon. Detached from the Iowa and ordered to Washington, D. C., for examination for promotion, and then home to await orders.

Steele, J. M., Surgeon. Ordered to duty at the torpedo station at Newport, Rhode Island.

Marine-Hospital Service.—Official List of Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the United States Marine-Hospital Service for the Seven Days ending October 12, 1899:

- Murray, R. D., Surgeon. To proceed to Key West, Florida, for special temporary duty. To assume command of the service at Key West, Florida, in accordance with orders of May 15, 1899.

- Carrington, P. M., Surgeon. To proceed to New York as inspector of unserviceable property.

- Perry, T. B., Passed Assistant Surgeon. To report to the chairman of the board of examiners, New York, for examination to determine fitness for promotion.

- Woodward, R. M., Passed Assistant Surgeon. To report to the chairman of the board of examiners, New York, for examination to determine fitness for promotion.

- Vaughan, G. T., Passed Assistant Surgeon. To report to the chairman of the board of examiners, New York, for examination to determine fitness for promotion.

- Wengenbaker, C. P., Passed Assistant Surgeon. To proceed to Bristol, Tennessee, for special temporary duty.

- Decker, C. E., Assistant Surgeon. To proceed to San Diego, California, and assume command of the service, relieving Assistant Surgeon L. E. Copher.

- Greene, J. B., Assistant Surgeon. To report to the chairman of the board of examiners, New York, for examination to determine fitness for promotion.
Casualty.
Assistant Surgeon W. R. McAdam died of yellow fever at Key West, Florida, October 12, 1899.

Society Meetings for the Coming Week:
MONDAY, October 23d: Medical Society of the County of New York (annual); Lawrence, Massachusetts, Medical Club (private); Cambridge, Massachusetts, Society for Medical Improvement; Baltimore Medical Association.

TUESDAY, October 24th: Tri-State Medical Society of Alabama, Georgia, and Tennessee (first day—Chattanooga); New York Dermatological Society (private); Metropolitan Medical Society, New York (private); Buffalo Academy of Medicine (Section in Obstetrics and Gynecology); Medical Society of the County of Putnam, New York (semiannual); Richmond, Virginia, Academy of Medicine and Surgery.

SATURDAY, October 28th: New York Medical and Surgical Society (private).

Births, Marriages, and Deaths.

Borns.
Turman.—In Lassiter, Virginia, on Wednesday, October 11th, to Dr. and Mrs. Alexander Emmett Turman, a daughter.

Married.
Bostwick—Nelson.—In Ansonia, Connecticut, on Wednesday, October 11th, Dr. Benjamin Earle Bostwick, of New Milford, Connecticut, and Miss Clara Hubbell Nelson.
Clark—Greene.—In Shuqualak, Mississippi, on Tuesday, October 10th, Dr. N. G. Clark, of Pratt City, Alabama, and Miss Minnie L. Greene.
De Munden—Bellinger.—In New York, on Wednesday, October 11th, Mr. Frederick W. De Munden, son of Dr. John T. De Munden, and Miss Sadie Bellinger.

Kline—Hall.—In New York, on Thursday, October 12th, Dr. Charles Demarest Kline, of Nyack, New York, and Miss Charita Irma Hall.
Lavinder—Fair.—In Ponce, Puerto Rico, on Thursday, September 28th, Dr. Claude Henry Lavinder, of Lynchburg, Virginia, and Miss Frances Moore Fair.
Moore—Stanton.—In New York, on Wednesday, October 11th, Dr. John William Moore, of Atlantic Mine, Michigan, and Miss Helen Louise Stanton.
Mortimer—Brown.—In New York, on Wednesday, October 11th, Dr. Samuel E. Mortimer and Miss Mary Wells Brown.
Peck—Anderson.—In Chester, Pennsylvania, on Wednesday, October 11th, Dr. George A. Peck, of New Rochelle, New York, and Miss Letitia Anderson.
Ramsay—Selden.—In Hampton, Virginia, on Wednesday, October 11th, Mr. Harvey Reynolds Ramsay and Miss Isabella Randolph Selden, daughter of Dr. Charles Selden.
Robbins—Blanchard.—In Sherborn, Massachusetts, on Tuesday, October 10th, Mr. Warren C. B. Robbins and Miss Florence Blanchard, daughter of Dr. A. H. Blanchard.
Taylor—Ransom.—In Buffalo, on Wednesday, October 11th, Dr. Edwin Stanton Taylor, of Philadelphia, and Miss Martha Ransom.

Died.
Collier.—In Rochester, New York, on Wednesday, October 11th, Laura M. Collier, wife of Dr. M. S. Collier.
McAdam.—In Key West, Florida, on Thursday, October 12th, Dr. W. R. McAdam, United States Marine-Hospital Service.

Letters to the Editor.

THE TESCHNER EXERCISE TREATMENT.

134 East Sixtieth Street, New York, October 7, 1899.
To the Editor of the New York Medical Journal:
Sir: In to-day's issue of the New York Medical Journal there appeared a paper by Dr. Louise Erich containing a report of cases of scoliosis and flat foot, treated by the "Teschner method."

Permit me, through the columns of your journal, to take exception to Dr. Erich's modification of my treatment, and especially to the reason assigned for this modification. I have held, and still do hold, that I obtain the best and most rapid result with the heaviest weights that the patient can exercise with, with rhythm and grace.

My patients are not required to "lift more" at each succeeding treatment, as stated by Dr. Erich, but they are expected to improve in their work, as will be seen by reference to my words, which she quotes, viz.:

"As the amount of work performed depends upon the last previous record of that patient, that record must be improved upon, unless there is a good and sufficient reason to the contrary."

Dr. Erich has had an opportunity of seeing my patients treated, but she has not had the advantage of
that personal training which I consider it necessary that any one should have who would undertake this work, execute it understandingly, and expect good and rapid results.

It is the lack of training and the timidity resulting therefrom which lead the doctor to the idea that she might overwork the patient's heart if she did not modify my method.

In the closing remarks of my paper, quoted by Dr. Erich, I specifically call attention to "the beneficial effect upon the heart's action, as shown by the diminished frequency of the pulse and the increase of pulse pressure after each treatment, as shown by Basch's sphygmomanometer." I have treated over a hundred cases of sclerosis (privately) and among the patients there were some with weak hearts, lesions implicating one or more valves, hypertrophy, dilatation, and even fatty degeneration, and in no case was the slightest injury inflicted; on the contrary, they all improved markedly, as can be attested by the physicians who referred them to me and by the patients themselves, who were enabled to undergo great exertion and exhibit endurance without the slightest discomfort.

As to the doctor's discovery that flat feet are benefited, I must again refer to her quotation. In next to the last paragraph of my closing remarks it is distinctly so stated.

The greatest benefit comes to them from the heaviest work, and not from the light foot exercises—the heavier the work, the more rapid the change in conformation—and the pain should disappear in one or two weeks, not only after the lapse of nine months, and then partially so.

I must, however, express my gratification at the showing made in the report of cases, as it demonstrates that, even if the results were slow and obtained by one who was not properly trained to the work, inferior handling by this method gives infinitely better results than by any other known treatment.

Taking it all in all, Dr. Erich is certainly to be congratulated upon her results.

 Jacob Teshiner, M. D.

Professor Kossmann on Certain Technical Terms.

[Translation.]

Berlin, September 15, 1890.

To the Editor of the New York Medical Journal:

Sir: In a letter from my highly esteemed colleague Dr. A. Rose, published in your journal, vol. lxx, No. 6, page 212, I find my name mentioned in a connection that leads me to think that Dr. Rose has misunderstood a remark of mine, perhaps made with undue brevity in a letter, concerning "policlinic" and "astyclinic." My view is as follows: In classical Greek—probably also in modern Greek—πόλις means a town as a municipality, as a political organism; ἀυτή, on the other hand, conveys a geographical idea, that of a collection of houses. Κλινώδος is an adjective derived from κλίνω, a bed. An "astyclinic," therefore, is an institution for the treatment (outside of a hospital) of the sick of a town who are confined to bed; a "policlinic," however, can be only an institution established by the municipal government for the care of those who are sick abed. It is alike improper to call an institution for treating the sick who are not confined to bed either a "policlinic" or an "astyclinic."

Whether it is grammatically more correct to write "policlinic," "policlinic," or "policlinic" is another question. The answer is as follows: "Policlinic" is admissible according to modern Greek usage, but not according to classical usage. Both "policlinic" and "policlinic," however, are correct forms according to classical usage. Yet, the ancients, although partial to the connective -io- in analogous word formations, avoided it for the most part in compounds of τοῖος, in order not to give rise to confusion by reason of the similarity in sound to the word τοῖος, gray (πολιοκράτωρ, having gray temples; τοιάρχος, the heart of a town).

But allow me, Mr. Editor, not only to answer these little side questions, but also to say a few words on the main question. Since, then, I am not a beer-drinking and pipe-smoking pedant, as Dr. Ellis seems to imagine every educated German to be, but a man who has pursued the objects of his research in many countries, and believes himself almost as capable as a smart American [als ein smarter Amerikaner] of distinguishing the important from the unimportant, I ask: Is an international technical language important or superfluous for us physicians? My readers will probably answer unanimously that for the learned of all nations uniform technical expressions are in a high degree important for the progress of our science.

I ask further: From what languages are these technical expressions to be taken appropriately? Answer: Since for two thousand years Greek and Latin medical terms have been in international use, and since to exchange them for terms taken from any other living tongue would provoke the self-conceit of other nations and meet with insurmountable opposition, the only proper course to follow is to employ technical expressions, both those now existing and those yet to be formed, taken from the so-called classical languages.

Finally, I ask: Is it proper to create or accept technical terms that are linguistically incorrect? Answer: No, it is not proper. Incorrect expressions, so long as they have not come into general use, are unintelligible without some added explanation; but their coming into general use will do more—it will hinder the adoption of correct expressions—because our professional brethren who are learned in languages can not be expected knowingly to run counter to the rules of a language intrusted to them.

From this it follows, then, that a person who knows nothing of Latin or Greek should seek the advice of some one who is learned in those languages when he attempts to create a new medical expression. If a man who was unable to play a scale correctly were to execute one of his own compositions in a circle of musically educated persons, it would be taken as the height of naivety. How, then, can a man pass around such words as "appendinflammatus," and the like, in a circle of men who are accustomed to regale themselves with Horace and Tacitus, and expect them to adopt them?

R. Kossmann, M. D.
Constitutional and Legal Safeguards in Criminal Cases.—When one accused of a criminal offense enters a court of justice sitting for the purpose of determining his innocence or guilt of the crime charged, he is protected by constitutional guarantees and presumptions of law, wisely designed to guard the innocent from the untoward and sometimes pernicious chain of circumstances which often falsely bespeak guilt. In all criminal cases the place of trial must, by virtue of the United States Constitution, lie in the State and district where the crime has been committed. This provision prevents the possibility of taking the prisoner to a distant State, where it would probably be impossible for him to secure evidence to disprove or combat that produced by the prosecution. The manner of trial, according to the guarantee of the United States Constitution, shall be, in federal cases, by jury, and by a similar guarantee contained in the constitutions of the several States the trial of prisoners for crimes against the respective States shall also be by jury. These guarantees, together with the wise laws which generally prevail for the purpose of securing unprejudiced juries, insure the prisoner a reasonably fair trial.

The first, and probably one of the most important, intemdtions of the law in the prisoner's favor is the presumption of his innocence. This presumption can only be overcome by the production of evidence on the trial so strong as to remove from the mind of the jury every reasonable doubt as to his guilt. The rule has been examined in civil matters, and it has been shown that the jury, after weighing the evidence, are to give their verdict in accordance with the preponderance of evidence; but in criminal matters, it must be observed, the rule is different. Here the jury can not find the accused guilty unless the evidence indicating guilt preponderates so greatly over that calculated to show innocence as to remove from the mind of the jury every reasonable doubt of the defendant's guilt.

In the manner of producing the evidence against the prisoner the solicitude of our Constitution and laws for justice to the accused is again shown. In civil matters, if a witness is far distant from the place of trial, or if he is sick and unable to appear in court, his deposition may be taken and produced upon the trial with a like effect as his personal statement made before the jury, or perhaps even greater; but not so in criminal matters. Here the Constitution says he shall be confronted by the witnesses against him—that is, he shall meet them face to face—and they shall testify in open court and in his presence. The prisoner is insured the right of compulsory process to obtain witnesses in his favor, and is spared the necessity of being himself required to testify. Moreover, he is guaranteed the right of being informed of the nature and cause of the accusation against him, and is assured the assistance of counsel for his defense. And, above all, when once acquitted of the crime charged, his innocence can never again be judicially questioned. But, notwithstanding all these legal barriers thrown about the accused, it is apprehended that many innocent men have suffered because of inadvertent circumstances, or perhaps through indiscretions. The evidence of circumstances is, as all know, often most convincing, and yet sometimes leads to absolutely false conclusions.

Rules Governing Admission of Evidence in Abortion Cases.—In order to understand more particularly what character of evidence is admissible to prove the commission of the crime in consideration and the amount and weight of such evidence necessary to fix the guilt, an examination will be made of a few cases in which the evidence has been passed upon and the prisoner's guilt or innocence determined by the jury. But first a brief reference will be had to the general rules of law regulating the admission of evidence.

In the trial of a case before a jury, whenever either party offers evidence, the admissibility of that evidence is a question of law to be decided by the judge. If the judge decides that the evidence is proper and admissible, it then becomes the province of the jury to weigh and determine the effect of that evidence. The judge, in passing upon the admissibility of the evidence, as well as determining whether it is relevant to the question at issue. In determining this, recourse is had, if in a civil matter, to the pleadings, or preliminary written statements of the facts or conditions claimed by the respective parties; if in a criminal matter, to the indictment or information, and herein will be found many technical discussions, which can be neither interestingly nor profitably examined.

The general rule, that the best evidence of which the case in its nature is susceptible is required, has been heretofore referred to. This rule simply means that when a certain fact can be shown by authentic evidence a secondary or inferior grade of evidence will not be admitted to prove the same; if, for instance, the contents of a certain letter or writing are desired to be proved, then the letter or original writing itself is the only admissible evidence; if, however, it can be shown that the letter is lost or destroyed, then secondary evidence of its contents may be admitted.

Similar in principle to this rule is the one rejecting as incompetent all hearsay evidence. The rule regarding hearsay evidence is that the witness may testify as to facts lying within his own knowledge, but that he can not testify from information given by others. There are, however, a number of exceptions to this rule which figure very importantly in the trials of the class of cases we are about to examine. One of these exceptions, or apparent exceptions, is that the expressions of another showing his bodily or mental feelings at the time they were made may be given in evidence by a witness who was present, where the physical or mental condition of such party at that time is relevant to the question in issue. Another and important exception, and one which it is difficult to adequately and clearly express in few words, is the rule that the circumstances and statements forming part of the res gestae are admissible in evidence; by the term res gestae is meant all of those circumstances and things which are related to or throw light upon the real question in issue. Mr. Greenleaff, in his philosophical work upon Evidence, in describing this rule, said: "The affairs of men consist of a complication of circumstances so intimately interwoven as to be hardly separable from each other. Each owes its birth to some preceding circumstance, and in
its turn becomes the prolific parent of others; and each, during its existence, has its inseparable attributes and its kindred facts, materially affecting its character, and essential to be known, in order to a right understanding of its nature. These surrounding circumstances, constituting part of the res gestæ, may always be shown to the jury, along with the principal fact, and their admissibility is determined by the judge, according to the degree of their relation to that fact, and in the exercise of his sound discretion; it being extremely difficult, if not impossible, to bring this class of cases within the limits of a more particular description. * To illustrate this rule, if one running from a room in which a murder had just been committed were heard to use certain expressions or make certain statements, those expressions or statements would be competent as part of the res gestæ, they tending to throw light upon the main question in issue. As a general rule, the circumstances or declarations offered in proof as part of the res gestæ must be contemporaneous with the main fact under consideration and so connected with it as to illustrate its character. It has been held, however, that where the witness reached the murdered person twenty seconds after the injury and heard him say, "I'm stabbed; I'm gone; Dan Hackett stabbed me," this evidence could be admitted as part of the res gestæ. The admissibility of evidence under this rule must depend largely upon the circumstances of the particular case, as will be more particularly and practically seen in observing its application in the cases hereafter examined.

More properly the foregoing rules admitting evidence of statements expressive of bodily and mental feelings, and statements which are part of the res gestæ, are not, in fact, exceptions, but are apparently exceptions to the rule deharring hearsay evidence, for the witness in neither of these cases attempts to testify as to the truth of the subject matter of the declaration, but simply as to statement or expression which he heard.

There are, however, several real exceptions to the rule. One of these exceptions, which is of material importance in this class of cases, is that dying declarations will be received as evidence of the fact which they recite. This rule is not applicable in civil matters, but only in cases of homicide, and such declarations are then admissible only for the purpose of showing the circumstances of the death. Such declarations must, however, be made while in extremis, the party realizing his condition and entertaining no hope of recovery. The theory upon which this class of statements is received as evidence of the fact recited is that a situation so solemn and so awful is considered by the law as creating an obligation equal to that which is imposed by a positive oath in a court of justice.†

Another exception which sometimes has an important bearing in this class of cases is the rule that confessions of the prisoner, or, in civil matters, admissions against interest, may be admitted in evidence to prove the subject matter of their contents. In view of this exception and of the great zeal shown by certain ministerial officers whose duty it is to apprehend and retain custody of the accused, to procure condemning evidence, often irrespective of the merits of the case, one who is so unfortunate as to have fallen under suspicion, perhaps by force of untoward circumstances, for which he is not accountable, should have this rule in mind.

and carefully guard his utterances lest some intentionally innocent remark, made under the excitement of the occasion, be repeated in court, possibly with a slight alteration of wording or a change of expression, to convey an impression of guilt not intended and not justified by the facts.

These are the principal rules of evidence adverted to in determining the admissibility of evidence in this class of cases. An examination will now be made of the cases themselves for the purpose of ascertaining the weight and effect of the evidence when admitted before the jury.

(To be continued.)

Path of Current Literature.

Exalgine Poisoning.—Poisoning by exalgine is rare. A case was recorded by Dr. Lemitte in the British Medical Journal for June 11, 1898, and quoted in the New York Medical Journal for July 2, 1898. In the Lancet for September 30th this year, Mr. J. Bell records a case of recovery in the Government Civil Hospital, Hongkong, after the enormous dose of a hundred and fifty grains taken by a Chinese male adult. The symptoms resembled those of opium poisoning. The patient was unconscious, intensely livid, with pin-point pupils, and full, bounding pulse. The temperature was 100.8° F. He had vomited once. The urine contained one fifteenth albumin. Treatment consisted of thirty grains of salicylic acid by the nasal tube and one fiftieth of a grain of atropine hydromellicr. Two hours later, one hundredth of a grain of atropine and small quantities of milk and coffee were given. One hundredth of a grain of atropine during the night. Next morning he was out of danger, but remained weak for some days.

Intoxication from Toxalbumins, etc.—Dr. Mary McDowell Shick (Pennsylvania Medical Journal, September), in a paper on this subject, formulates the following conclusions: 1. Bacteria themselves are not always essential to the production of diseases resembling those ordinarily produced by micro-organisms. 2. All soluble poisons produce similar lesions. 3. It is possible, under natural conditions, for an individual to become poisoned with the toxines without the direct agency of the bacteria. Generally, however, this does not occur. In drinking water, the poison is well diluted; in foods, we do not, as a rule, eat those in which putrefaction has progressed sufficiently for the toxine to have been developed. 4. The trend of present experiments would seem to indicate that a special antitoxine for each toxine is not necessary; but, rather, some substance which in all cases will act as a stimulant to the lymphoid tissues of the organism. 5. Considering the similar symptoms and lesions of all intoxications, one general line of treatment may be followed, being modified to suit individual cases.

Encouraging Results of Koch's Investigations of Malaria in Italy.—According to the Journal of the American Medical Association for October 7th, Professor Koch, who sailed for the Dutch East Indies in August to continue his research on malarial infection, announces as the results of his studies in the Tuscan
Maremna that he is convinced that man is the only host of the malarial parasite during the months from summer to summer. The alternating host, the mosquito, is found all the year around, but only during the summer months does the parasite find in its body the warmth necessary for its development. When summer arrives the mosquito derives the parasite from one person and transfers it to others, thus transmitting infection. The connecting link in the infection is therefore the recurrences during the fall and winter, in the persons infected the summer before. If these recurrences could bejugulated—and this is possible with quinine—the infection could be eradicated before the arrival of summer; the mosquitoes would then find no parasites and malarial infection would gradually die out. When he first arrived in Tuscany, in April, all the cases he could find were old, dating from 1898. Suddenly, on the arrival of warm weather, large numbers of fresh cases were noted—a regular epidemic. He concludes that it is possible with the aid of quinine to break down the bridge that connects season with season, and in this way exterminate malaria.

Uric Acid as a Cause of Asthma.—L. H. Watson (Southern Medical Record, February; Laryngoscope, September) favors the theory advocated by Haig and others that asthma represents the effects of uric acid on the circulation in the thorax, and that it is paroxysmal for the same reason that epilepsy and migraine are so, in accordance with the natural fluctuation of the uric acid and the amount of substance passing through the circulation. He quotes a case cured and another improved by treatment based on this theory.

Epithelioma as a Sequel of Psoriasis and the Probability of its Arsenical Origin.—Dr. M. B. Hartzell (Boston Medical and Surgical Journal, October 5th), in a paper read at the annual meeting of the American Dermatological Association, said that the patient, a woman of thirty-five years, had been affected with psoriasis since the age of fourteen. Upon the outer side of the left heel there was an ulcer two inches in diameter with shallow edges and a deep centre. The palms and soles showed marked keratosis, with cornlike elevations. Upon the elbows and trunk were a few patches of psoriasis, which presented nothing unusual. In the left groin was a bosedulated tumor the size of a small orange, firm and elastic except at the summit, where it was soft. The patient had been given arsenic in considerable doses over long periods of time. The patient developed the horny condition of the palms and soles about two years after the psoriasis had made its appearance. Later small superficial ulcers occurred beneath the horny masses and obstinately refused to heal. At this time the tumor in the groin speedily ulcerated, forming a deep, fungating, foul ulcer which discharged abundantly. This was so followed by a more or less continuous fever, loss of appetite, rapid emaciation, and death in about two months. Histologic examination of an excised section of the border of the ulcer demonstrated beyond doubt its epitheliomatous nature. Ten cases of associated epithelioma and psoriasis had been reported. In all of them the psoriasis was of quite long standing; in all but three there was some form of keratosis; and in all epitheliomatous change took place beneath one or more of the horny excrescences. In all in which mention was made of treatment, eight out of eleven, arsenic had been given in considerable quantity over a long period. It was noteworthy that in fifty per cent, of the cases the lesions were multiple and that one half of the patients were under the age of forty. In conclusion, the writer remarked that the evidence thus far in our possession was of such a character as to permit us to accept as very probable, at least, the arsenical origin of the epithelioma in these cases.

In the discussion that followed, some of the members held that the epitheliomatous change was due to the continued irritation produced by the excessive keratosis and could not be directly traced to the arsenic. Dr. Hartzell, in closing, maintained that the arsenic being the cause of the keratosis was responsible for the epithelioma that it superinduced.

Massage with Quicksilver.—Rindloffisch (Münchener medizinische Wochenschrift, August 29th; Medical News, October 7th) has devised a plan by which one can massage rheumatic joints without doing them more injury than good. He takes the inflamed hand and sinks it in a deep, wide glass, which is two thirds full of quicksilver. The quicksilver exerts an equal pressure on every portion of the fingers, and this increases very rapidly as the fingers sink farther into it. The hand is sunk slowly into the quicksilver and withdrawn twenty or thirty times at one sitting. After the second sitting he was pleased to observe a marked diminution in the swelling, and in four days the joint was almost normal. The method recommends itself for wider trial.

The Natural Limitation of Syphilis.—Dr. J. D. Thomas (International Medical Magazine, September) says that syphilis, like all other eruptive diseases, has a clinical limit; and, again, like the other eruptive diseases, its sequelae may be unlimited. Syphilis loses its contagious character in less than four years; its sequelae may last as long as the patient lives. In cases thoroughly treated it may lose its contagious character in one year; this clinical fact we know from occasional observation, wherein some of our patients, against advice, marry at this early period, but do not infect their wives, and hence have healthy children. The far limit of the contagion we know from observation; but its near limit in individual cases we are unable to settle. If any of the lower animals were susceptible to the disease we could, by experimental inoculation, tell each patient when the disease had lost its contagious character, and thus be enabled to state how soon the marriage relation might be entered upon.

And he adds: "When a woman, newly married, comes to me with syphilis, after marrying a man who had had syphilis three or four years before the wedding, I make bold to tell her that she did not acquire the disease from her husband, but from some fresher syphilitic."

In this connection the statement of Jonathan Hutchinson, quoted in our issue for October 7th, that "hereditary syphilis would disappear if the rule was generally adopted that two years' interval after infection should elapse before marriage," will be recalled.

Ergot in Chronic Malaria.—Dr. A. Jacobi, in a paper on this subject in the St. Louis Medical Era for October, arrives at the following conclusions:

1. There are cases of chronic intermittent fevers with large traumatation of the spleen which, after having resisted the action of quinine, arsenic, methylene blue, eucalyptus and piperin, are benefited by ergot.
2. When enlargement of the spleen is not old and not
firmly established, the contracting effect of ergot is noticed within a reasonable time. 3. The attacks will disappear before that diminution in the size of the spleen is very marked. 4. Though temperatures after the employment of ergot remain irregular and are now and then somewhat elevated, chills, as a rule, are not noticed with this elevation. 5. Plasmodia do not seem to disappear from the blood so rapidly as they do after quinine when the latter is effective. But even while some are still present, the attacks being more or less under control, the patient will feel better. 6. Complicating local pain requires additional treatment with ice, or cold douches, or heat. Chronic hyperplasia demands iodide of potassium or iodide of iron. Digestive disorders may indicate, as they often do when quinine is expected to act before the employment of ergot, an emetic, or a purgative, or stomachics. 7. An experience extending over forty years, in which I have used ergot in many instances, justifies me in asserting at least this much: that there are many cases of chronic malaria, apparently intractable, that will get well with ergot. 8. There are cases occasionally in which the return of elevations of temperature after the successful use of ergot makes the combination of ergot and quinine, or ergot and arsenic, advisable, though quinine and arsenic were not successful previously. 9. Ergot, like quinine, probably by its sudden contracting effect on the spleen, and the forcing of large quantities of plasmodia-laden blood into the circulation, in chronic malaria when hydremia and spleen tumor are excessive, is capable of bringing on the very first attack of chills and fever. 10. Recent cases of malaria have got better or were improved under the extensive use of ergot, but many resisted a long time. That is why acute cases should rather be treated with quinine."

Proceedings of Societies.

SOCIETY OF ALUMNI OF BELLEVUE HOSPITAL.

Meeting of June 7, 1889.

The Vice-president, Dr. Charles E. Quimby, in the Chair.

Report of a Case of Extensive Thoraoplasty.—Dr. L. W. Hotchkiss made this report. The patient was a man, twenty-four years old, a member of the Thirteenth United States Infantry, who, at the battle of San Juan in July, 1898, had been struck by a Mauser bullet, which, after perforating the left arm, had entered the chest and emerged behind the right shoulder. The man had been exposed for several days after the battle, and had then been brought down to the hospital at Siboney, where it was found that an empyema had developed. This had been incised and drained, a small rubber tube being inserted for that purpose. Subsequently, the patient had been brought to New York on the transport Seneca and was admitted to Bellevue Hospital late in July. At that time his general condition was very bad; he was very much run down, had numerous bedsores, and a badly drained empyema of the left chest, the lung on that side having collapsed. As soon as possible, Dr. Hotchkiss had enlarged the original opening in the chest, excising one or two pieces of rib and putting in some large drainage tubes. These had drained fairly well, and the man had gained somewhat in health and strength. Later on, the collapsed lung having failed to expand, a more extensive operation had been decided on, in order to obliterate the large pus cavity on that side of the chest, which contained between one and two quarts of fluid, and could contract no further. The procedure which was followed was along the line of the Schede-Estlander operation. The incision extended from the second rib in front round to about a corresponding point posteriorly; this large flap had then been raised, and a portion of the third, fourth, and fifth ribs excised, together with the costal pleura. The man's condition had been such as to demand very rapid work and transfusion with large quantities of normal salt solution. The flap, which consisted of skin and muscle, had been allowed to sink in against the collapsed lung. By this operation the cavity had been so much reduced in size that it only contained a very few ounces of fluid. The patient had rapidly gained in flesh and strength, and had soon been able to be up and about the ward. At the time of his discharge from Bellevue a sinus remained, which led into a cavity containing about six or eight ounces of fluid, and during the past winter he had entered the Hood-Wright Hospital for the purpose of having this smaller cavity obliterated, as the sinus had once become occluded, and he had suffered from pain and fever. This second operation was done in March, 1899. A curved incision was made, commencing just below the left nipple and extending backward to and along the posterior edge of the scapula, the muscles being partially divided. The scapula was retracted from the side of the chest in order to gain access to that part of the chest cavity. Upon raising the scapula, the ribs, which had been partially removed at the previous operation, were more widely excised still farther back; and the tissues covering them were allowed to sink in. Only the upper three ribs—the third, fourth, and fifth—were excised, as the lower part of the chest cavity had already been obliterated by the previous operation. There was some infection of the wound following this operation, and a severe secondary hemorrhage from one of the intercostal arteries.

At the time of the report a small sinus still remained, which discharged a little pus. There was considerable resonance over the upper portion of the left chest, showing that the upper part of the lung on that side was expanded. The lower portion of the lung was collapsed, retracted, and fastened down by adhesions.

The function of the left arm, Dr. Hotchkiss said, had at first been much impaired as the result of section of the muscles which pass over the tip of the scapula. Since the operation, however, the function of the arm had gradually improved, and the patient had a good range of motion at the shoulder joint. The patient's general health was good. Dr. Hotchkiss said he hoped that the small cavity which still remained would heal by granulation without further operative intervention.

Dr. John F. Erdmann asked the opinion of the chairman as to the value of the pneumatic cabinet in a case of this kind, for the purpose of expanding the collapsed lung.

The chairman, Dr. Quimby, replied it would be easy enough to expand the lung, but it would not remain expanded, as there was nothing to hold it there. The
A Case of Resection of the Sigmoid Flexure for Carcinoma.—Dr. Hotchkiss also reported this case. The patient was a man, fifty-two years old, who had suffered from an annular carcinoma of the sigmoid flexure, which had given rise to symptoms pointing to some internal growth for some months before the patient came under observation. Dr. Hotchkiss said that in the other cases he had seen there had usually been a history of acute obstruction, and, in one or two instances which had come under his observation, this had been practically the first symptom of the trouble. The patient was admitted to the Hood-Wright Hospital on March 9, 1899. There was no venereal history. He had always indulged moderately in alcoholics. About two years ago he had been seized with a sudden pain in the abdomen; as he was constipated, he took a laxative, and when his pain and constipation had been relieved he had had some bleeding from the bowels, lasting for eight or ten days and accompanied by the passage of a number of large clots, resembling liver, as he described them. There had been a continuous loss of flesh and strength, together with a pain on the right side, with paroxysms of severe pain every three or four weeks, followed by hemorrhage from the bowels. He had visited various hospitals, where his trouble had probably been regarded as due to hemorrhoids.

An exploratory laparotomy was done at the Hood-Wright Hospital in March last. The abdomen was opened in the left semilunar line, revealing a growth in the sigmoid flexure. One small mesenteric gland immediately below the growth was found to be enlarged. There were no symptoms of obstruction, and no marked distention, the case being an ideal one for an immediate resection of the gut and an end-to-end anastomosis, which was accordingly done. Considerable difficulty had been experienced in adjusting the Murphy button, the only one available being the largest of the three original buttons, which was usually too small for the large intestine. This had made the anastomosis rather an awkward one, and obstructive symptoms were feared. For some days after the operation he had had pain and distention, which were relieved by the rectal tube and magnesia.

When the patient was discharged, on April 20th, he had not yet passed the button, and it had not been discharged until the forty-third day. Since then the patient had been free from all symptoms, and had gained some flesh and strength. He had not suffered from constipation since.

The growth removed had been submitted to Dr. E. K. Dunham for microscopical examination. Dr. Hotchkiss said he had not yet received a report from the pathologist, but the growth was apparently an annular carcinoma. It projected into the lumen of the gut, diminishing its calibre so that it would only admit the little finger. Its gross appearance was typical of carcinoma.

Dr. W. Evelyn Porter said that he had seen several cases of malignant disease of the large intestine in which both the immediate and ultimate results of operation were satisfactory. In one such case, where he had assisted Dr. Outerbridge, the same sized Murphy button which Dr. Hotchkiss had referred to was inserted, with the same gratifying result. In that instance the button was discharged rather earlier than in Dr. Hotchkiss’s case, but this fact had given rise to practically no unfortunate symptoms. The disease in that case had been absolutely proved to be carcinoma. The last time he heard from the patient, which was about a year ago, she had been enjoying excellent health.

(To be concluded.)

Book Notices.

The Ready Reference Handbook of Diseases of the Skin. By GEORGE THOMAS JACKSON, M. D. (Col.), Professor of Dermatology in the Woman’s Medical College of the New York Infirmary and in the Medical Department of the University of Vermont, etc. With Seventy-five Illustrations. Third Edition, revised and enlarged. New York and Philadelphia: Lea Brothers, 1899. Pp. viii-17 to 647. [Price, $2.50.]

The third edition of Dr. Jackson’s book following so soon upon the second, which appeared in June, 1896, testifies greatly to its worth and the popularity it enjoys. And this is not surprising, as it is one of the very best of the short treatises on the subject which have been published. Though all the subjects are treated in a concise manner, yet that does not mean that any important points are omitted. On the contrary, the necessary features for diagnosis are sharply drawn and designated.

The treatment is given as fully as it is possible, and the subject is enlarged by the addition of an extensive formulary. This third edition has been brought up to date by a thorough revision, and new sections have been added, dealing with dermatitis from the Röntgen rays, blastomyecotic dermatitis, and pityriasis alba atrophicans, among others.

The type, paper, and general get-up of the book are in every way excellent, and it is a pleasure to recommend it to those desirous of having at hand an accurate and concise presentation of the subject of dermatology.

The volume opens with a description of Holländer’s apparatus and method for using superheated air as a hemostatic. A number of instances are cited to prove the value of the method as an advance over the actual cautery, and cases of lupus in which cicatization was brought about are illustrated by reproductions from photographs. The report of Grancher’s lectures on the treatment of tuberculous disease seems to be concluded.
Among other foreign clinics reported are those of Jac- coud, Fournier, Grawitz, and Lassar, and the names of Harc, Koen, and Gibney appear among those of the American contributors.

Miscellany.

The Features of the Fruitful Scientific Mind.—Pro- fessor Sir Michael Foster (Lancet, September 16th), in his presidential address to the British Association for the Advancement of Science, said:

“What are the qualities, the features of that scientific mind which has wrought, and is working, such great changes in man’s relation to Nature? In seeking an answer to this question we have not to inquire into the attributes of genius. Though much of the progress of science seems to take on the form of a series of great steps, each made by some great man, the distinction in science between the great discoverer and the humble worker is one of degree only, not of kind. As I was urging just now, the greatness of many great names in science is often, in large part, the greatness of occa-
sion, not of absolute power. The qualities which guide one man to a small truth silently taking its place among its fellows, as these go to make up progress, are at bottom the same as those by which another man is led to something of which the whole world rings. The features of the fruitful scientific mind are in the main three.

"In the first place, above all other things, his nature must be one which vibrates in unison with that of which he is in search; the seeker after truth must himself be truthful—true to the truthfulness of Nature. For the truthfulness of Nature is not wholly the same as that which man sometimes calls truthfulness. It is far more imperious, far more exacting. Man, unscientific man, is often content with 'the nearly' and 'the almost.' Nature never is. It is not her way to call the same two things which differ, though the difference may be measured by less than the thousandth of a milligramme or of a millimetre or by any other like standard of minuteness. And the man who, carrying the ways of the world into the domain of science, thinks that he may treat Nature's differences in any other way than she treats them herself, will find that she resents his conduct; if he in carelessness or in disdain overlooks the minute difference which she holds out to him as a signal to guide him in his search, the projecting tip, as it were, of some buried treasure, he is bound to go astray, and the more strenuously he struggles on the farther will find himself from his true goal.

"In the second place, he must be alert of mind. Nature is ever making signs to us, she is ever whispering to us the beginning of her secrets; the scientific man must be ever on the watch, ready at once to lay hold of Nature's hint, however small, to listen to her whisper, however low.

"In the third place, scientific inquiry, though it be preeminently an intellectual effort, has need of the moral quality of courage—not so much the courage which helps a man to face a sudden difficulty as the courage of steadfast endurance. Almost every inquiry, certainly every prolonged inquiry, sooner or later goes wrong. The path, at first so straight and clear, grows crooked and gets blocked; the hope and enthusiasm, or even the jaunty ease, with which the inquirer set out leave him and he falls into a slough of despond. That is the critical moment calling for courage. Struggling through the slough, he will find on the other side the wicket gate opening up the real path; losing heart, he will turn back and add one more stone to the great cairn of the unaccomplished.

"But I hear some one say, these qualities are not the peculiar attributes of the man of science: they may be recognized as belonging to almost every one who has commanded or desired success, whatever may have been his walk of life. That is so. That is exactly what I would desire to insist upon, that the men of science have no peculiar virtues, no special powers. They are ordinary men, their characters are common, even commonplace. Science, as Huxley said, is organized common sense, and men of science are common men, drilled in the ways of common sense. For their life has this feature. Though in themselves they are no stronger, no better than other men, they possess a strength which, as I just now urged, is not their own, but is that of the science whose servants they are. Even in his apprentice ship, the scientific inquirer, while learning what has been done before his time, if he learns it aright so learns it that what is known may serve him not only as a van-

tage ground whence to push off into the unknown, but also as a compass to guide him in his course. And when fitted for his work he enters on inquiry itself, what a zealous, anxious guide, what a strict and, because strict, helpful schoolmaster does Nature make herself to him! Under her care and inquiry, whether it bring the inquirer to a happy issue or seem to end in naught, trains him for the next effort. She so orders her ways that each act of obedience to her makes the next act easier for him, and step by step she leads him on toward that perfect obedience which is complete mastery. Indeed, when we reflect on the potency of the discipline of scientific inquiry we cease to wonder at the progress of scientific knowledge. The results actually gained seem to fall so far short of what under such guidance might have been expected to have been gathered in that we are fain to conclude that science has called to follow her, for the most part, the poor in intellect and the wayward in spirit. Had she called to her service the many acute minds who have wasted their strength struggling in vain to solve hopeless problems, or who have turned their energies to things other than the increase of knowledge; had she called to her service the many just men who have walked straight without the need of a rod to guide them, how much greater than it has been would have been the progress of science and how many false teachings would the world have been spared! To men of science themselves, when they consider their favored lot, the achievements of the past should serve not as a boast, but as a reproach."

The New York Academy of Medicine.—At the last stated meeting, on Thursday evening, the 19th inst., Dr. C. L. Dana presented a paper on Locomotor Ataxia, which was discussed by Dr. G. M. Hammond, Dr. F. Peterson, Dr. Joseph Collins, and Dr. B. Sachs.

At the next meeting of the Section in Laryngology and Rhinology, on Wednesday evening, the 25th inst., Dr. James F. McKernon will read a paper entitled A Contribution to the Techincs of Modern Uranoplasty, which is to be discussed by Dr. Hartley, Dr. Knight, Dr. Phillip, Dr. Duel, and others.

At the next meeting of the Section in Obstetrics and Gynecology, on Thursday evening, the 26th inst., a paper entitled The Umbilicus; its Development, Deformities, Diseases, and Dressing, will be read by Dr. A. Ernest Gallant. Cases will be presented and specimens will be exhibited.

The Ninth Annual Meeting of the American Electrotherapeutic Association, which was held in Washington, D. C., on the 19th, 20th, and 21st of September, was, we are informed, very successful in point of attendance and interest. The programme included thirty-six papers and the reports of seven standing committees on scientific questions relating to the medical application of the electrical current. The proceedings of the convention will be published at an early date. The following officers were elected for the tenth year: President, Walter H. White, M. D., of Boston, Massachusetts; first vice-president, D. Percy Hickling, M. D., of Washington, D. C.; second vice-president, Charles O. Files, M. D., of Portland, Maine; treasurer, Richard J. Xunn, M. D., of Savannah, Georgia; secretary, George E. Bill, M. D., of Harrisburg, Pennsylvania. The next annual meeting is to be held in New York city on September 25, 26, and 27, 1900.
The London Cancer Society has, according to the Medical Times for October, commissioned Dr. A. E. Duffy to proceed to the United States for the purpose of collecting data regarding cancer, and especially to study the investigations being made at Buffalo. A prize of fifty dollars has also been offered by the society for the best essay on cancer.

A Dog with False Teeth.—La Nature, says the Medical Times for October, tells a story about a dog belonging to a well-known English dentist which was scarcely able to feed itself, owing to loss of teeth. It has been fitted with an artificial set (including four canine teeth and as many molars) mounted on a plate in the ordinary style, and now eats meat and even gnaws bones without difficulty, so as to have gained considerably in weight.

Medical Arrangements for the Transvaal.—According to the British Medical Journal for September 30th, Major Dodd, R. A. M. C., embarked with other officers from Aldershot on September 23rd. He will be embarking and disembarking officer at Durban. He is accompanied by Quartermaster H. S. Brook, R. A. M. C. Miss M. Russell, superintendent army nursing service, and a staff of nurses left for South Africa on the same date. The Secretary of State for War has been unable to accept the services of a large number of men of the Volunteer Medical Staff Corps who had volunteered for employment with the army medical service in South Africa. The Red Cross has notified its willingness to place its aid and resources at the disposal of her Majesty’s forces in South Africa, and the Order of St. John of Jerusalem is ready for ambulance duty if required. In India the medical and other branches are prepared to move as soon as definite instructions are received from the war office. The army medical corps is ready to form, according to an Aldershot correspondent of the Daily Telegraph, eleven field hospitals and seven bearers companies. The Press Association says it is a matter of comment that many officers who have been selected for service in connection with the Transvaal were employed this summer during the manoeuvres on Salisbury Plain. According to the Press Association, the admiralty have communicated with the Union Steamship Company, with a view to ascertaining what vessels they had available for transport purposes to the cape as hospital ships. The admiralty were furnished with the requisite information, and decided to take over from the company the steamers Trojan and Spartan to serve as hospital ships in South African waters and for other purposes. The work of fitting up these vessels as hospital ships has already been commenced at Southampton, and they are expected to be completed in a week. In all probability when finished they will steam out to Cape Town with a view to being utilized between there and Natal in the event of war breaking out. The ships Kinfuans Castle and Gaika, from the Royal Arsenal Dockyard, Woolwich, will embark two field hospital companies with medical equipment on a war scale.

The Sanitarian in the Vegetable Garden.—The British Medical Journal for September 30th says that one of the most distinguished of our sanitarians, Dr. Vivian Poore, recently gave a demonstration of his method of utilizing closet refuse and its results to a number of members of the Sanitary Institute during the congress recently held at Southampton. At his invita-
by Samuel M. Gray, C.E., of Providence, Rhode Island, and Allen Hazen, S.E., of New York; Water Purification, by George W. Fuller, S.E., of New York; Typhoid Fever, by Dr. Victor C. Vaughan, of Ann Arbor; Milk Supply, by Ira Johnson, of Grand Rapids; Tuberculosis among Animals and Man, by Dr. George W. Dunphy, V.S., of Quincy; The Duties and Powers of Local Boards of Health and Health Officers, by Judge Aaron V. McAlvay, of Manistee; Local Health Administration, by Dr. Hiram R. Mills, of Port Huron; Vital Statistics as a Branch of General and Local Health Administration, by Dr. Cressy L. Wilbur, of Lansing; and General Health Administration, by Dr. Henry B. Baker, of Lansing.

The Massachusetts General Hospital.—From the Boston Weekly Transcript for September 15th we learn that very considerable additions to this hospital are said to be about to be made. In the centre of the grounds is to be erected a new operation building, to contain a large amphitheatre, a medium-sized operation room and three smaller ones, with the requisite sterilizing and other accessory rooms. Additions and extensions will be made to the nurses' home. A "Domestic Building" is also to be erected, to contain stores, dormitories for the domestics, and dining rooms for the nurses, domestics, and house officers. It will also contain a drug department, photograph and X-ray rooms.

Copyright in Lectures.—The Medical News for October 7th refers editorially to a recent decision of the English high court of justice in a case in which the defendant was Lord Rosebery, the ex-premier of England, while the plaintiff was the London Times. The noble lord, in furnishing speeches for a forthcoming volume, Appreciations and Addresses, to his publisher, John Lane, copied almost verbatim the text of certain speeches from the parliamentary reports of the Times. The Times brought suit to restrain publication of the volume, contending that its report of the speeches was covered by copyright, and that the speaker had no right in the premises so far as the form of the speeches went.

The decision was rendered in favor of the Times. The argument of counsel was that unless a man takes the usual steps to secure the copyright on a lecture before its delivery, when once it is delivered it becomes public property. As to the rights of the newspaper in the matter, it is conceded that it is the reporter who gives form to the matter, and it is in this that the copyright lies. The reporter corresponds to a translator from a foreign language, and just as a translation may be copyrighted so may the report of a speech.

As American law follows English law very closely in this matter, says the News, it is evident that those who are present at medical lectures may bring out such lectures and secure a copyright on them. Of course a lecturer has his protection in being able to secure a copyright before the delivery of a lecture, but he may seldom be in a position to have his lectures in such shape as to take advantage of this right. The News suggests that he might, however, copyright certain important lectures of a course before their delivery, so that the set would be noticeably incomplete without them, and thus secure the same object as in copyrighting the whole course in advance.

"Hypnotism" in Animals.—The British Medical Journal for September 30th says editorially that it has long been known that certain animals could be "hyp-
blue-glass theory to osteopathy, this generation has seen the rise and fall of many a new thing in "cures." The medical profession must reckon with this tendency. It must expect and it must be prepared to reckon with these new systems of healing. The experience of the past should have taught it the folly of abuse and persecution of the exploiters of new faith. Often it is itself responsible for their existence. Often its own failure to embrace certain essential truths has been the opportunity of the fanatic or the fakir. About the nucleus of value which resides in the sun-bath and the blue-glass craze gathered. The misappreciation of manipulative measures of treatment is the excuse for osteopathy. The psychological principle in human health and disease, neglected of scientific medicine, is the still living soul of that dead body of superstition which goes by the name of Christian Science. These systems have their day and cease to be, leaving behind them a residuum of truth as their legacy to scientific medicine. It becomes the profession to deal with these symptoms as they come and go—not by abuse and antagonism, but by bringing them, each and all, and as speedily as possible, up to the searchlight of a common standard of education demanded by the state. There is no danger in the recognition of alien practitioners of any system, provided they are able to meet the requirements of such a standard.

The Tri-State Medical Society of Alabama, Georgia, and Tennessee is announced to hold its eleventh annual meeting in Chattanooga from Tuesday, October 24th, to Thursday, October 26th, inclusive. The railroads offer reduced rates on the certificate plan. Many well-known members of the profession, including Dr. J. M. Mathews, Dr. J. A. M. Cartledge, Dr. Lewis McMurtry, Dr. C. A. L. Reed, Dr. Cunnan Pope, Dr. Duncan E. W., Dr. W. E. B. Davis, and Dr. George H. Simmons, are expected to be present.

Survival for More Than Twenty-three Years after Removal of the Tongue for Epithelioma.—In the Transactions of the Pathological Society for 1876 Mr. Christopher Heath reported a case of removal of the tongue for epithelioma. In the British Medical Journal for May 29, 1899, cited by Treatment for September 28th, a further report, showing that the patient lived over twenty-three years, was made by Mr. Heath.

Inoculation of English Troops against Malaria.—According to the Southwestern Medical Record for September, a large number of troops leaving England for Natal were inoculated against malaria. The result will be interesting to watch.

The Growth of Science.—Professor Sir Michael Foster, in his presidential address at the meeting of the British Association for the Advancement of Science, said that whoever, working at any scientific problem, had occasion to study the inquiries into the same problem made by some fellow-worker in the years long gone by, came away from that study humbled by one or other of two different thoughts. On the one hand, he might find, when he had translated the language of the past into the phraseology of to-day, bow near was his forerunner of old to the conception which he thought, with pride, was all his own, not only so true but so new. On the other hand, if the ideas of the investigator of old, viewed in the light of modern knowledge, were found to be so wide of the mark as to seem absurd, the smile which began to play upon the lips of the modern was checked by the thought, Will the ideas which I am now putting forth, and which I think explain so clearly, so fully, the problem in hand, seem to some worker in the far future as wrong and so fantastic as do these of my forerunner to me? In either case his personal pride was checked. Further, there was written clearly on each page of the history of science, in characters which could not be overlooked, the lesson that no scientific truth is born anew, coming by itself and of itself. Each new truth was always the offspring of something which had gone before, becoming in turn the parent of something coming after. In this aspect the man of science was unlike, or seemed to be unlike, the poet and the artist. The poet was born, not made; he rose up, no man knowing his beginnings; when he went away, though men after him might sing his songs for centuries, he himself went away wholly, having taken with him his mantle, for this he could give to none other. The man of science was not thus creative; he was created. His work, however great it might be, was not wholly his own; it was in part the outcome of the work of men who had gone before. Again and again a conception which had made a name great had come not so much by the man's own effort as out of the fullness of time. Again and again we might read in the words of some man of old the outlines of an idea which in later days had shone forth as a great acknowledged truth. From the mouth of the man of old the idea dropped barren, fruitless; the world was not ready for it and heeded it not; the concomitant and abutting truths which could give it power to work were wanting. Coming back again in later days the same idea found the world awaiting it; things were in travail preparing for it, and some one, seizing the right moment to put it forth again, leaped into fame. It was not so much the men of science who made science as some spirit which, born of the truths already won, drove the man of science onward and used him to win new truths in turn.

It was because each man of science was not his own master, but one of many obedient servants of an impulse which was at work long before him, and would work long after him, that in science there was no falling back. In respect to other things there might be times of darkness and times of light. there might be risings, declenances, and revivals. In science there was only progress. The path might not be always a straight line; there might be swerving to this side and to that; ideas might seem to return again and again to the same point of the intellectual compass; but it would always be found that they had reached a higher level—they had moved not in a circle, but in a spiral. Moreover, science was not fashioned as is a house, by putting brick to brick, that which is once put remaining as it was put to the bond. The growth of science was that of a living being. As in the embryo phase followed phase, and each member of the body put on in succession different appearances, though all the while the same member, so a scientific conception of one age seemed to differ from that of a following age, though it was the same one in the process of being made; and as the dim outlines of the early embryo became, as the being grew more distinct and sharp, like a picture on a screen brought more and more into focus, so the dim gropings and searchings of the men of science of old were by repeated approximations wrought into the clear and exact conclusions of later times.
The title assumes that either such a relation is supposed to or does exist, and if the latter, the question arises, What sort of a relationship is it? Shall we consider that the nasal condition produces the asthma, cause and effect, or is the ethmoid condition an accidental complication of the asthma, or are they both the outcome, the result, of some depraved condition of the general system which has its outward expression in these two diseased processes; and, if this latter is the case, what is the exact rôle of the nasal disease in the asthmatic complex?

In order to define the position from which this sketch of the pathology is taken we must explain our conception of the condition called asthma. An accepted theory is that there must be first an irritability of the bronchial structures which makes possible the explosion of energy known as asthma. This hyperaesthetic condition is frequently the result of disease, and the multiplied and oft-repeated attacks always induce chronic inflammation, and consequently greater irritability. Secondly, we usually find that some other structure is diseased or oversensitive. An irritation or disturbance of it sets into motion the spasm of the bronchial apparatus. Thus we find that one asthmatic has a nose, another a stomach, another a kidney, or even an ovary, and if to these vulnerable organs certain stimuli are applied an explosion results. But to connect the nose, stomach, or kidney with the bronchial tubes a third element must be brought in—namely, the vasomotor system, or, as it is more often put, the neurotic habit.

Now, setting aside with only a word the very broad question as to the explanation of all the phenomena of asthma, we find that the nose can be considered in this sketch as only one of the diseased conditions, although a very frequent one, which can initiate an attack of asthma. This is the case whether we view the final explosion as one purely of vasomotor effects, or whether with greater probability we believe both a vasomotor paralysis and contraction of the bronchial musculature are necessary to the phenomena.

The question now stands, then, with diseased nose, irritable or diseased bronchial tubes, and neurotic or irritable vasomotor nerve fibres assumed as existing, What is the initiatory of the attacks, and why do they occur? What is there peculiar in the nasal conditions which brings on these distressing results, and what happens to the nose to make the affair begin? In some cases the way is plain—namely, the pollen of the hay-fever patient or emanations from animals give the start through the existing nasal conditions. In other cases our evidence is not so clear. Take a case where the patient has a few polypi, and every morning at three or four o’clock, especially after an evening dinner, he is awakened suddenly by an asthmatic attack, and, his polypi being removed, his condition gradually improves and the asthma disappears. What is there different in the nose other than the absence of a little tissue, and what did the polyps do to make the trouble? Evidently one link in our chain has been broken, and thus its power destroyed. Now, if the polyps were not causative of the asthma, then it must follow that if we could break any of the other links of our chain we could also destroy its spell. Does not this happen when we give our patient potassium iodide, or send him to Colorado, and he has no more asthma? His polyps do not necessarily disappear, and we have often learned that the moment he returns to the East he has his trouble over again. I have thought that the rarefied air in those cases either helped the bronchial condition, or the change of environment, with fresh air and exercise, improved his neurotic habit, or both, and thus other links were broken than the nasal. Whether this is true or not, however, it is evident that the mere presence of the polyps does not explain the attacks—the environment and life of the patient have much to do with it.

Now, what shall we say of so subtle a difference as exists, polyps and all, in a case such as I beg Dr. Rice’s pardon for relating before he has read his paper on Clinical Phases. You have probably all seen exactly similar cases. This patient, to relate the case most briefly, had the ordinary symptoms of sneezing catarrh. Every morning, with greater or less regularity as to the hour, he would awaken with attacks of sneezing and have a most violent coryza for two hours, during which period, for a few weeks previous to my seeing him, he had begun to have a little asthma. He came at the suggestion of an eminent specialist in another city who wished me to remove the polypoid tissue, anticipating a speedy relief to the symptoms. The patient was a very healthy looking young man of twenty-eight years, engaged in business in the city. The conditions which obtained in his nose were hypertrophies of the edematous type on both middle turbinates and the usual pale swelling on the inferior turbinate. On the left side a spur from the septum with a septal hypertrophy anterior to it were also present. The most irritable areas existed on the left side. The regulation treatment was instituted. The spur was removed, the edematous tissue...
first snared off as far as possible, and then the galvano-
cautery applied to it and to the inferior turbinal and
septal hypertrophies. He stopped smoking, a most he-
roic task for him, and took exercise. He was also more
out of doors, and, in short, did everything he was told,
only to find that he was benefited for a time by each of
the many measures, and that later his edematous tis-
ue in a measure returned. He discovered that when he
was occasionally in the country and slept away from
home he escaped his attacks, which had continued less
in degree from the start. On one occasion a whole week
elapsed without an attack, and the first night at home
he had a short one, and the second a very severe one.
Something led me to inquire as to the arrange-
ment of his bed and room, and I found the usual
equipment. I suggested a hair pillow. He used it,
and from then on he was free from trouble, being able
to sleep on any other pair of pillows in the house except
his own, which had a musty smell. Now comes the
curious part of it—namely, that, being free from the
irritation, his middle turbinates, without any treatment
whatever, diminished in size, and since then I have
seen him a number of times during the three years that
have elapsed. He can exercise violently without short-
ness of breath, and smokes inveterately. Evidently irri-
tation of irritable nerve fibres had something to do
with the formation of edematous tissue, and hence with
asthma, and the case shows the excessive and, withal,
elective irritability of the nerve fibres supplying the
respiratory tract, and especially that of the middle tur-
binate region. But it must be remembered that therape-
utics were of no avail until the feathers were changed,
and that there was certainly, as the result of the subtle
but powerful influence of that particular brand of
feathers, not only an irritation to the nerves, but the
irritation, being long continued, caused edematous tis-
ue to develop, and thereby the contact and pressure
sufficient to induce asthma. Hence we have plainly
one cause of nasal disease assured—namely, that cer-
tain irritations applied to certain nerve fibres will pro-
duce congestion and chronic inflammation with swell-
ning and watery discharge. This leads to the soaking of
the tissues of the middle turbinate region, edematous
hypertrophies appear, and later these assume the form
of polypi. This may be said to be true not only of the
hay-fever subject, and cases like the one related, but
occurs also with many dusty occupations, such as, for
example, bakers and workers in grain elevators. But
back of all is one factor—namely, the peculiar hyper-
sen-sitiveness of the nerves which will allow of such
results. This is to be referred to either inherited or
acquired peculiarities. The latter may result from dis-
ease, but once present seem persistently operative, and
are sometimes well-nigh irremediable. Whether in-
herited or acquired, there seems always to go hand in
hand with this, certainly locally, and, I am led to be-
lieve, frequently all over the whole body, a thinness or
flabbiness of the blood-vessel walls and a vasomotor
responsiveness to irritation which make possible the ex-
plosions which are the bane of the existence of these
afflicted mortals.

On another occasion I have ventured to suggest that
this might be considered as always the inherent pecu-
liarity of the neurot ic subject. These supposed condi-
tions would explain the headache, the asthma, the neu-
ralgias, the dyspepsias, and the nervous prostrations,
all of which at the start are but explosions, the vagaries
or spasms of one or another set of blood-vessels. Later,
by excessive distention and oft-repeated stretching, the
blood-vessel walls in the afflicted areas become perma-
nently stretched and flabby, and thus actual organic
lesions are possible. This will apply most aptly to the
pathology of the subject under consideration.

In the main the lesions of the ethmoid or, generally
speaking, middle turbinate region are of an edematous
nature. How rarely if ever does one see a case of gen-
uine atrophic rhinitis with asthma! The lesions are
therefore hypertrophic in character, and at first con-
fined to the mucous membrane. In something more
than sixty cases, purulent ethmoid disease has only ex-
isted three times, and in these it was secondary to long
previous existence of edematous tissue. Marked dis-
ease of the bony structures occurred in these sixty
cases some six or eight times without purulent condi-
tions, and was here also due to inveterate polyp for-
mati on, which latter I am led to believe is always the rule
—i.e., that the disease of the mucous membrane pre-
cedes that of the bone. Septal spurs and bends seem to
keep up middle turbinate disease and increase the pos-
sibility of pressure, which seemed in a great many
cases to explain asthma. But in all, whether compli-
cated or not, there was hypertrophic disease always pres-
ent, and usually of the edematous type. Very often
these edematous hypertrophies were polyoid in form.

We have, therefore, in our cases merely to explain
the production of hypertrophies, edematous and other-
wise, to have our pathology of nasal lesions clearly dis-
cussed. The explanation as I view it is something like
this: We have as a result of our environment and the
conditions obtaining in the bony framework of the nose
in any given individual an hypertrophy of the middle
turbinate. Such a condition usually gives a pretty defi-
nite microscopical picture. Suppose that the patient
has hypersensitive nerve development, and the slightest
variations of temperature, or the mildest forms of irri-
tation on this hypertrophy, produce congestion with
consequent increase in volume. With vasomotor irrita-
bility these congestions are more stormy and more often
repeated than in simple hypertrophy, and the stretch-
ing of the venous trunks occurs. In simple hypertro-
phies and in non-neurotic subjects these latter are well
supplied with muscular coats, and soon contract down
again to their normal size. But given locally in one
small area, or inherently in the whole membrane, a lack
of tone to the muscular coats, vasomotor ataxia, or the deficiency in the amount of muscle fibre inherent to the neurotic habit, and the result is inevitably permanent stretching and flabbiness. Just as inevitably in time there follows the possibility of filtration, and some waterlogging of the tissues results.

Now, an oedematous hypertrophy always distinguishes itself microscopically from the more healthy variety by thin-walled blood-vessels and the existence of a material exuded into and between the fibres of the connective tissue. This forces the fibres apart and destroys the function of the smooth muscle cells which are always present in a healthy mucous membrane, and they disappear, making it still more impossible for the tissue to contract. Into certain depending areas there would naturally occur more soaking, and, some weak fibres having given way, we should have bulging of certain areas, and anon the polyp bud comes forth to increase and wax great as it depends more and more.

All this simply explains oedematous tissue. How does it produce asthma? All such processes as the above seem to be favored by pressure, which adds to the passive congestion and growth of the thickening, and brings into existence contact areas and increase of pressure. With the latter present, the initiative of the asthmatic attack is easy, if at the same time the bronchial apparatus is also diseased or susceptible. With cooling off of the night air, for example, such as always occurs toward morning, and the recumbent position favoring flux of blood to the head, the sensitive nerves in the oedematous areas are suddenly stimulated and an increased flow of blood to the nose causes swelling and immediate increase of pressure. We have assumed excessive nerve sensitiveness. Hence, the pressure which a normal nerve would receive, and by which it would not be annoyed, is to the sensitive individual a sufficient cause to bring into play the reflex action in the bronchial tract, and the latter consequently has its vasomotor equilibrium disturbed. Some swelling of the bronchial mucous membrane undoubtedly takes place, and in the same way there is a stimulation to the pneumogastric which immediately causes a spasm of the bronchial musculature to take place, and then our asthmatic is in the toils. Pressure in the nose seems, therefore, to be necessary to the causation, and explains why many cases are so much relieved by the removal of the main mass of the offending tissue in the nose. Often, however, we are unable to get cessation of attacks even after apparently most complete removal, and this would perhaps be explained by the fact that the avenues having been once established, it takes only the slightest irritation of the hypersensitive nerves to start an impulse sufficient to set the bronchi into a spasm without actual pressure on the contact areas. Such is the persistency of the convulsive habit; also we must consider that by the same line of reasoning as explained in nasal pathology, the bronchial structures not only become more easily convulsed, but are by virtue of these attacks actually diseased, becoming distended, congested, and thickened.

The pathology in brief, therefore, involves step by step the following sequence, it being understood that the whole process may take years to develop, or it may occur in a much shorter time. We conceive first the existence of a simple hypertrophy in the nervously hypersensitive individual. The vasomotor instability and the nerve irritability cause further development of the lesions in the middle turbinate region, and produce in time waterlogging of the tissue. This becomes then an oedematous hypertrophy, and this latter may become a polyp. These lesions produce pressure over sensitive areas, which through constant irritation from pressure become more sensitive, so that reflexly there is produced a bronchial vasomotor disturbance. If once the reflex avenue has been opened it is easy to conceive that the disturbance, which is felt first as a sort of oppression or weight in the chest, becomes later a genuine obstruction to breathing, and, there being added to this a spasm of the bronchial tubes, we have a full-fledged asthma.

This explains the genesis of those cases of asthma which are essentially nasal in type. Now there are asthmatics whose attacks are not apparently nasal, but who are nevertheless made very much better, and sometimes entirely relieved, by removing any existing nasal disease. These people have their disturbance only under peculiar conditions, such as overindulgence in food or drink, disturbed kidneys, a cold, a rheumatic explosion, or the onset of a menstrual epoch. These apparently work through the vasomotor link in our chain. There are cases which baffle us entirely and in which our pathology is hazy because we do not get at the cause; but oftentimes our reward comes by the discovery, as in the feather case, which is by no means an exceptional one, of an aetiological factor quite outside of our ordinary conception of the causation. Occasionally we find our only remedy is change of environment, and then we remove one or another of our causative factors.

The deduction is plain, therefore, that when treating many of the pathological conditions in the nose, whether asthma exists or not, we must often look outside of the nose, and many times outside of the body, for the causes which lead up to them.

THE CAUSE OF DEATH FROM INDUSTRIAL ELECTRIC CURRENTS.

By R. H. CUNNINGHAM, M.D.,
CLINICAL ASSISTANT IN NEUROLOGY, VANDERBILT CLINIC, COLUMBIA UNIVERSITY, NEW YORK.

(Concluded from page 587.)

The Action of Strong Currents on the Heart.—Theoretically one would suppose, as has been briefly mentioned elsewhere in this paper, that the cardiac muscle, or at least the ventricular part of it, was killed out-
right or paralyzed by the current. It is conceivable, of course, that if the lethal current were of enormous intensity and of enormous electromotive force, not only the heart but the entire body might be disrupted instantaneously into atoms; but the possible action of such currents, which no one has produced artificially, does not concern us. So far as all previous experiments with the ordinary commercial currents in use during the present time indicate, none of these currents seem capable of producing such a total instantaneous disintegration of the body; consequently, no further consideration of the subject from this aspect need be given.

If the thorax of an animal is opened immediately after a strong continuous electric current, or strong alternating current of medium frequency, has passed through the heart via the skin, and the heart is exposed, a careful scrutiny of the still quivering ventricles will show that though the coordinated beat of the heart as a whole is absent, the various minute bundles of muscle fibres are alternately contracting and relaxing with considerable vigor in various parts of the ventricles. But as the right cavities of the heart become more and more distended by the accumulating venous blood, the asynchronous quivering of the various little bundles of muscle fibres grows less and less, until finally every trace of muscular contraction disappears from the greatly distended ventricle. In other words, the current seems to have thrown the heart into the condition known to the physiologist as delirium cordis, or preferably, fibrillar contraction. That there is no question of the instantaneous death of the muscle cells of the heart, nor of their paralysis, nor of profound molecular changes invisible under the microscope, resulting from the direct disruptive action of the current is readily proved if Porter's method or any other method for recovering the excised dog's heart from the condition of fibrillar contraction is employed. This method consists essentially in the perfusion of the blood-vessels of the heart with warmed defibrinated dog's blood diluted with 0.8 per cent. saline solution, and by means of it I have repeatedly caused the fibrillating excised hearts of numerous electrocuted dogs to beat coordinately again, and to continue contracting coordinately for fully an hour, and ceasing then only because of the discontinuance of the artificial circulation. As is frequently the case where efforts are made to recover the fibrillating heart, I found it often necessary to check all movement of the cardiac fibres by plunging the hearts into iced saline solution for some moments before the hearts of these "electrocuted" dogs could be made to resume their coordinate beats.

That the heart of an "electrocuted" dog excised soon after the application of the lethal shock can be made readily to recover its coordinate contractions by artificially restoring the circulation through it, clearly disproves the idea that the muscular substance has been paralyzed or killed by the current. Had the fibres been paralyzed, no movements would have been noticed after the passage of the shock; and had the muscle been killed, naturally no recovery could have occurred on restoring the circulation. Probably the effect of the electrical stimulus has been to disturb the balance of the hypothetical intracardiac coordinating mechanism, the nature and location of which modern physiologists are still endeavoring to elucidate.

As is well known, the mammalian heart is easily thrown into the condition of fibrillar contraction by various other kinds of stimuli, mechanical, chemical, and by cold (McWilliam); consequently the effect is physiological in nature, and not one that is only characteristic of the electric current. Naturally, the hearts of some animals of the same species respond to such stimuli more readily than they do in other animals. Currents of a strength fully sufficient to throw the hearts of some animals into fibrillar contraction will thus entirely fail, as I have noted previously, to produce that effect. Certain kinds of electrical current—for instance, the various kinds of alternating currents of moderate frequency, the intermittent, and the coarsely pulsatory continuous currents—produce this variety of cardiac contraction more readily than a current of continuous electro-motive force. Accidental contact with such currents is thus more liable to be followed by fatal results than the contact with a current of equal maximum voltage, but whose electro-motive force is continuous.

As it is thus clearly proved that the rapid death following the brief application of a strong electric current to the dog, and also very probably to man, if the observations of autopsies made upon criminals immediately after their electrocution is considered, is due to the fact that the electric current or stimulus induces fibrillar contraction of the heart, a condition from which the hearts of the higher mammals very rarely recover spontaneously, it should follow logically that certain animals possessing hearts that easily recover spontaneously from the state of fibrillar contraction would be killed by such currents only with great difficulty, or, in fact, mainly by asphyxia. Consequently I endeavored repeatedly to electrocute frogs and a small

---

* June 6, 1899. This fact, as well as several others of less importance mentioned in this paper, which lack of space prevents me from enumerating in detail, has been recently described also by Prevost and Battelli (Comptes rendus de l'Académie des sciences, séances de mars 15 et 27). As some of their observations are almost identical with some of those described in certain portions of this paper, it should be noted in justice to myself as well as to those investigators that this paper, though completed during the latter part of February, 1899, was held back until March 31, on which date it passed into the hands of one of the prize committees of the Alumni Association of the College of Physicians and Surgeons, New York, where it remained until it was sent to the Journal.

‡ Ludwig and Hoffa (Zeit. für rat. Med., 1859, ix, p. 185) recovered the hearts of dogs and cats after they had ceased to beat by injecting cold calf's blood through the coronary arteries.
tortoise with the 115-volt continuous dynamo current, but, as had been expected, none of these animals could be killed by that current, and all of the frogs fully recovered within a few minutes. Two of the experiments were as follows:

**EXPERIMENT V.**—Small frog. Current from head to hind legs equalled 0.8 ampere. Three shocks of one minute duration at intervals of ten seconds. During the shock animal in a general tetric condition. For three or four minutes after the shocks marked general muscular relaxation was present, but in ten minutes the animal had completely recovered.

**EXPERIMENT VI.**—After exposing the heart of an etherized turtle by trephining the plastron and enlarging the orifice with a rongeur, the electrodes were applied to the tissues very close to each side of the heart. Current equalled 0.4 ampere, applied for one minute. Cessation of the heart beat during and for several moments after the stimulation. After an interval of about five minutes the same current was applied for four minutes. Result same as before. Left border of heart considerably charred, nevertheless it quickly recovered its coordinated contractions and continued to beat for a number of hours, when the animal was then killed by decapitation and removal of the still beating heart.

Thus these results fully accord with the various observations made by me upon the dog.

That the passage of a strong electric current, continuous or alternating, of a moderate frequency, through the heart via the skin throws the heart into the condition of fibrillar contraction is a fact which in my judgment is not so remarkable, for it has been long known to physiologists that the direct application to the exposed heart of magnet-electric currents (Weber, Ludwig and Hofka), continuous currents from batteries and from small physiological induction coils (Einbrodt, Mayer, Herbst, McWilliam), would produce such a condition in the hearts of certain varieties of animals. Herbst endeavored to produce this cardiac effect by applying the electrodes to the skin, but, as is proved by his negative results, the currents he employed were evidently too weak. Similarly Mann was unable to definitely influence the cardiac movements in man by the application of the electrodes to the skin in the region of the heart. Nevertheless, from the very definite results described in this paper, the conclusion is evident that the physiological action of the current upon the heart is the same whether it is applied directly to the heart or whether it is applied to the skin so that the heart is included in the circuit.

**On the Instantaneity of Death from Industrial Currents.**—According to the consensus of opinion, writers on the subject of death by the electric shock agree that such a death is instantaneous. Such, however, from the results of the preceding experiments, is not a fact. All the tissues of the body, the nervous system, the heart, etc., are clearly not killed instantaneously, and, as is evident, at least one of the most important nervous mechanisms, the respiratory centre, continues to act more or less perfectly for some moments after the cessation of a lethal current.

Judged from our tracings, from the experiences of three of my patients who had received severe but fortunately not lethal shocks, and from the published accounts of sixteen cases of recovery after electric shocks, there seems to be ample time before loss of consciousness occurs for the recipient of the shock to become fully aware of the fact that he is, or has just been, in contact with an electric current. Thus every one of the nineteen individuals mentioned above felt some very distinct form of sensation before consciousness was lost. Generally speaking, the sensation was not particularly painful, and was described by them as similar in character to the sensation produced by catching hold of the electrodes of a small but strong medical induction coil. Usually a sensation of tremendous pressure across the chest is also felt. Several years ago I had the opportunity of witnessing an electrical accident, which, fortunately, did not result fatally for the recipient. On this occasion I was standing close to a trolley car, watching one of the electricians, who was just on the point of removing a defective brush from the motor. He was partially beneath the car, with his right hand on the brush, when he inadvertently rested his left hand upon a live rail; immediately his muscles became tetanic and he was thrown backward in an instant, thus severing his connection with the live contacts. In a few moments syncope occurred. While in this state the respirations were at first rather rapid, later possibly a little slower and shallower than normal. His pulse was very soft, rapid, and slightly irregular, but soon became normal. In about thirty seconds consciousness returned. He then vomited once and was able to get up by himself, though he complained of feeling extremely weak. The next morning he informed me that the prostration had persisted for about two hours after the shock and then disappeared, leaving him feeling as well as ever. The electro-motive force of the current in this instance was about five hundred volts. How much actually passed through him one can not tell, but certainly not more than a very small fraction of an ampère.

Judging from our experimental results produced by applying milder currents for various lengths of time, the clinical manifestations exhibited in cases like the one just related seem to be produced as follows: As the
accidental contact with the live wires, rails, brushes, etc., is made, more or less pronounced general muscular contractions immediately occur. After a deep inspiration and expiration respiration may possibly be briefly inhibited, but quickly rebegins. Temporary inhibition of the action of the heart accompanied by a fall in the blood pressure is also manifest almost from the moment the shock begins. With non-fatal currents of brief duration the normal heart beat and the normal blood pressure are soon recovered. From the diminution of the blood pressure and the consecutive disturbance of the cerebral circulation, more or less syncope frequently occurs, from which the individual gradually emerges after the restoration of the circulation to the normal. In certain instances where a large portion of the current traverses the brain, as in those rather rare cases in which the live wires form contact with the head and the back of the neck, the underlying sensory motor centres of the brain may be stimulated to such a degree that in a few moments one or more general fits, quite similar in many respects to an epileptic fit, may be produced. With severe fits of this character most probably consciousness is lost, as in ordinary epilepsy, at the beginning of the fit. Consequently, should the cerebral anemia resulting from the lowered blood pressure and disturbed heart action not have induced syncope previously, the onset of a general fit in all probability would be accompanied by complete loss of consciousness.

Since death may occur in one of two ways in cases where the electric shock proves fatal—namely, from asphyxia, or more commonly from the complete extinction of the circulation and the consecutive cerebral anemia—undoubtedly death by the first method is far from being instantaneous, while in the second way, though it occurs very rapidly, nevertheless it is not absolutely instantaneous. Though "dead men tell no tales," it seems highly probable that before the brain becomes sufficiently anemic for consciousness to be completely lost, a brief period of conscious perception exists, immediately following the closure of the circuit. Just what the sensation during this brief period is must naturally for the present be simply surmised. From the experiences of the various cases mentioned above, the chief sensation perceived in fatal accidents during this brief period is most probably that of an electric current, and probably not of a very painful one at that. With the nearly instantaneous extinction of the cerebral circulation such a rapid and complete cessation of the functions of the cerebral cortex occurs that no time remains for sensations other than those of an electric current to be felt before the cerebral perceptive nerve centres have ceased to act. Even after the circulation has been entirely extinguished by stoppage of the heart beat, many of the medullary and spinal-cord centres in the dog continue to manifest evidences of activity, often for several minutes. Neither mode of electrical death is thus absolutely instantaneous. All that one can say definitely is that when the heart suddenly stops death occurs very rapidly. Just how long certain nerve centres in the medulla and spinal cord survive the extinction of the circulation is naturally a difficult thing to decide. From my experience with dogs, it seems to be a very definite fact that the above-mentioned nerve centres in some animals withstand the complete anemia for considerably longer periods than they do in other animals.

We may conclude, then, that none of the industrial electric currents can produce instantaneous death of the whole body, or even of the nervous system, unless the current density of such currents in the body is sufficiently great to produce immediate heat coagulation of the cellular elements and other components of the body. So far as I am aware, currents of such intensity and of the requisite electro-motive force are not to be found among the industrial varieties of electric currents.

Spontaneous Recovery after Electric Shock.—Obviously this subject is one that is of great interest not only to medical men but to the general community. Frequently during the past few years there have appeared in the public press, and in the medical press as well, usually after an official electrocution of some criminal, sundry editorials, short papers, and letters to the editor entitled "Who is the Executioner?" "Did the Doctors or the Electric Current kill — — ?" etc. By such queries it is evidently intended to cast doubt upon the real death of the criminal from the effects of the current, and to convey the idea that the pathologist by his autopsy was the one who caused the final death of the criminal. Consequently, as both the lay mind and the professional mind seem to be still uncertain as to the probability of the spontaneous recovery of an individual after a strong electric current has passed through him in such a fashion that a considerable portion of the current has traversed the heart, a brief discussion of this question seems quite apropos.

Many cases of electrical accidents bear witness to the fact that an individual may be in contact, usually imperfect contact, with conductors carrying currents of considerable intensity and of high electro-motive force for a considerable time, without such a current producing a fatal effect. In such cases possibly none of the current, or undoubtedly but a very small portion of the current, traverses the heart. Thus the coordinate contractions of the heart are not stopped, and after the flow of the current has ceased recovery soon occurs. As such currents may produce a dangerous, or even an ultimately fatal, asphyxia from partial or from complete inhibition of the respiratory movements during their passage, spontaneous recovery under such circumstances will depend naturally upon the degree of the asphyxia. If the nervous system has been profoundly asphyxiated before the current is stopped, spontaneous recovery, as in asphyxia produced by other
means, is naturally doubtful. In the milder degrees of asphyxia recovery is extremely probable.

But when the current through the body is a strong one—for instance, one of from one to eight amperes—and passes through the heart, that organ goes, as has been pointed out, immediately into the condition of fibrillar contraction. Spontaneous recovery of the highly organized human heart with complete restoration of the extinguished circulation, produced by even a very brief passage of a strong current, is extremely improbable. In fact, so improbable would such an occurrence be, judging from the difficulty with which the excited fibrillating dog’s heart is recovered by artificial perfusion of blood, that one may safely say that it would never do so spontaneously before the vitality of the central nervous system had become so reduced as to be incapable of recovery. After the arterial blood pressure has disappeared, I have never seen a single instance in a series of more than thirty experiments on dogs in which spontaneous recovery of the coordinated contractions of the heart with restoration of the general circulation occurred. Herbst and McWilliam have observed that after the brief application of the electrodes directly to the exposed heart of the dog a very brief period of fibrillation may be followed by the reappearance of a few coordinated beats. Should such recovery of the heart occur before the general blood pressure has become greatly diminished, possibly the slightly disturbed circulation may be restored. Once the general blood pressure has fallen to zero, the right heart rapidly becomes so overdistended with venous blood, which may coagulate in a few moments, that even though one or more feeble coordinate beats occur, the overfilled right heart can not empty itself with sufficient rapidity through the lungs so that the left ventricle can produce enough pressure in the aorta for the necessary blood to be forced through the coronary circulation rapidly enough for the spontaneously restored coordinate contractions to be maintained. As McWilliam has pointed out, the simpler the heart the more readily does it recover spontaneously from the condition of fibrillar contraction. Thus in the frog spontaneous recovery after severe shocks seems to be the rule.

With a brief postponement of the autopsy for a maximum period of one hour after the official electrical execution, if no signs of recovery are manifested by the executed criminal, undoubtedly the minds of all parties concerned may rest assured that the autopsy is performed upon an individual who can not possibly recover spontaneously, or, in fact, be recovered by any artificial means. But even at the end of an hour the excised heart of such an individual could be made very probably to beat again coordinately if it were perfused with blood.

Resuscitation after Electric Shock.—Although it has been emphasized by d’Arsonval, first in 1887 and later in 1894, that after an electric shock the individual should be treated by means of artificial respiration, as in case of the drowned, “since the condition after the shock is merely one of suspended animation in which the respiratory function is suspended,” it is clear, both from the results of others as well as from my own results, that in the majority of instances there exists absolutely no indication for the employment of such a measure. In fact, the emphatic recommendation of such a procedure is clearly based upon an utter misconception of the true physiological state of affairs present in the vast majority of individuals after a powerful electric shock. Only in those rare instances in which the current passes for a long time mainly through the brain and upper part of the spinal cord, but not to any extent through the heart, would there be a possible real indication for the performance of artificial respiration after the shock, and not even then unless very shallow movements or a complete absence of respiration were found to be present. Such a condition of asphyxia after contact with powerful currents is, however, quite rare, for, as a rule, accidental contact with live wires, etc., usually occurs via the hands or arms. Consequently, in fatal cases a considerable portion of the current undoubtedly traverses the heart. Naturally, the performance of artificial respiration in any case will do no harm, though how it can do any good when once the heart has ceased to beat and the circulation has been arrested I do not see.

It is evident from the state of affairs existing in the vast majority of instances after an apparently lethal shock has been received from an industrial current that, in order to resuscitate the individual or the experimental animal, due consideration must be had for the following existing conditions: First, that the heart is in the state of fibrillar contraction, a condition from which it will most probably not recover spontaneously; secondly, that the circulation of the blood is completely arrested; thirdly, that the central and peripheral nervous system are rapidly dying from the lack of blood supply; fourthly, that the right heart is rapidly becoming overdistended by the inflowing venous blood, thus very materially diminishing the chances of a spontaneous recovery of the heart; and lastly, that the longer the arrest of the circulation continues the greater is the liability of the blood to become clotted in the large veins and in the right cavities of the heart.

Such being the conditions, clearly the indications are to quickly restore the circulation, not only of the nervous system, to keep it from dying, but also of the heart, so that it may quickly recover its coordinated contractions. So far as I know, there is but one way in which this may be possibly accomplished—namely, by creating artificially a temporary circulation of a fluid capable of sustaining the heart and the nervous system, until the

heart has recovered sufficiently to maintain the circulation in the normal manner. Thus arterial transfusion toward the heart, or injection at considerable pressure, of some supporting fluid is indicated at the outset. Of all the various fluids recommended by therapeutists for

intravascular injection undoubtedly the defibrinated blood from another animal of the same species is the only fluid that will fulfill the requirement of maintaining the nervous system. Consequently defibrinated blood should be the supporting fluid selected for injection. However, the mere arterial injection of warmed defibrinated blood would not result in establishing the requisite mode of circulation, for the injected blood after passing through the capillaries simply continues to accumulate in the venous system and in the distended right heart, until finally the veins rupture or the general vascular pressure equals the pressure of the blood that is being injected. Obviously also, the overdistention of the heart very seriously impedes or, in fact, entirely prevents the reestablishment of the coronary circulation, an extremely important factor as regards the ultimate reestablishment of the coordinated heart beat. Therefore such an enormous increase in artificial respiration, except as a possible adjuvant to facilitate the outflow from the right heart, would be superfluous until after the establishment of the pulmonary circulation by recovery of the right heart.

With such an array of serious obstacles to be overcome the outlook for the invention of a simple, always ready, quickly applicable, and infallible method of resuscitation after electric shock is certainly far from promising. The mere probability of having to make an intravascular injection of human defibrinated blood, or even of the blood from some other species of animal, complicates the method to such a degree as to practically prohibit its application in the ordinary cases of accidental death from electricity. But the circumstances are entirely different in the experimental laboratory. There, all can be prepared properly beforehand, so that immediately after the experimental animal has received the electric current the various necessary procedures for its resuscitation can be performed rapidly and conveniently.

To carry out the method described below requires the assistance of at least two skilled assistants, and the services even of a third will be of great use very frequently. Naturally, the apparatus as figured below need not be quite so complicated, but for experimental purposes it is very convenient when arranged in that form.

Briefly stated, the apparatus (Fig. 4) in a general way closely resembles the well-known form of injection apparatus that has long been in use in many histological laboratories. The large bottle, P, that distributes the pressure to three smaller bottles (B, B, S), containing the injection fluids, is preferably connected to an air pump in constant action. By adjusting the vent cock, c, the required degree of pressure can be maintained easily. The large Woulfe bottles, B, B, can be made to empty their contents singly or together through a tube which is inserted into the carotid artery, by

the venous pressure and the overdistention of the heart should be prevented by establishing an outlet from the right ventricle for the injected defibrinated blood. With such an outlet the oxygenated blood injected into the arteries would circulate as desired through the nervous system and through the coronary arteries, but naturally no pulmonary circulation would be present. Thus opening or closing the proper pinchcocks that control the inflow of air and the outflow of fluid. The bottle S can be made to deliver its contents through the connection at T to the tube to the carotid artery by means of one of the arms of the y located on its exit pipe, or the contents of S may be discharged through the smaller of the tubes composing the long double-tube cannula.
that is passed via the large external jugular vein of the dog into the right ventricle of the heart. The larger tube of the double cannula is attached to a bottle from which the air is constantly exhausted by a vacuum water pump. The bottles $B$, $B$ are filled with warm defibrinated dog’s blood diluted with 0.8 per cent. saline, and the bottle $S$ is filled with very cold (1°C.) 0.8 per cent. saline solution. The action of the apparatus is as follows: After the electric current has arrested the circulation and the respiratory movements are no longer present, defibrinated blood is rapidly injected into the right carotid artery. At the same time blood is withdrawn from the right ventricle through the double cannula that has been passed down the external jugular vein after the current has been shut off. When enough of this dark venous blood has been collected an assistant empties it from the bottle, defibrinates it, and filters it through glass wool, so that it may be injected again into the arterial system. Should the heart not recover from the simple injection of the defibrinated blood, the tendency to further fibrillation may be diminished by allowing the ice-cold saline to flow into the right ventricle through one pipe of the double cannula. While one bottle of the defibrinated blood is being injected the other bottle may be refilled with fresh, diluted, warm defibrinated blood.

Generally in a few moments after the beginning of the injection the respiratory movements begin and become quite normal in depth, although slightly slower (Fig. 5). After a very strong shock the heart probably will not recover for some time, and often it will not recover its coordinate beat even though the injection is continued for over an hour. Nevertheless it still lives, for on exciting such a heart and injecting the defibrinated blood directly through the coronary vessels and applying ice to its exterior it will usually recover quite quickly. If the outflow from the right ventricle can not be maintained, either from frequent clogging of the tube or from clotting of the blood in the great veins and in the heart, absolutely no chance exists, according to my experience, for the recovery of the heart while it remains in the body. As long as the blood continues to be injected into the carotid, provided the outflow from the right ventricle is maintained, the rhythmical respiratory movements, and generally other movements also, continue. If the outflow becomes choked, the respiratory movements cease in a few moments, but they will return readily if the outflow is quickly reestablished. Furthermore, the earlier the artificial circulation is begun the greater the chance of success. Even within three to four minutes after breaking the current I have often found the blood clotted to such a degree in the right auricle and veins in certain dogs, especially when they had been fed on the morning of the experiment, that every chance of possible resuscitation was precluded. Numerous failures in maintaining the activity of the nervous system until the heart passes from the condition of fibrillation have taught me that the greatest care should be taken to have the inflowing blood of the proper temperature—namely, from 36° to 38° C. Should the blood become cool, the nervous system is killed very quickly. Thus in several instances I have been able to maintain a regular, rhythmical rate of respiration for over thirty minutes, but suddenly, on accidentally allowing blood of too low a temperature to flow into the arteries, the respiratory movements ceased very suddenly and permanently, although feeble coordinated beats were produced ultimately in the heart during the succeeding hour. In further attempts at rapid and complete resuscitation that have just been begun,* it is hoped, however, that such a mechanical obstacle will be done away with by causing the blood to flow through a long coil of small lead pipe surrounded by water kept at the proper temperature by a Bunsen burner. But even with the above-mentioned technical obstacles present, such promising results as I have obtained in maintaining the nervous system for such a long time after the shock, and in ultimately recovering the heart from fibrillation, clearly prove that with a sufficient supply of properly warmed defibrinated blood the nervous system can be kept alive until both the coordinated heart beat and the arrested natural circulation are resumed.

As has been mentioned previously, such a method, although applicable for laboratory experiments, is not, I regret to say, sufficiently simple and ever handy for the practical treatment of individuals after accidental electric shocks. Unfortunately, owing to the conditions present, only such a method of procedure will possibly produce the required resuscitation. Possibly it may be considered by some that the modified Ringer’s artificial serum or 0.8 per cent. saline solution might be used instead of the defibrinated blood, but so far as my experience goes with such fluids they can not replace the defibrinated blood. In the numerous instances in which I tried them the respiratory centre promptly failed to recover.

Summary.—1. Industrial electric currents, which traverse the whole body transversely or longitudinally in sufficient intensity, kill because fibrillar contraction of the heart is produced and not, as has been hitherto surmised, by producing a total paralysis of that organ or by killing it outright.

2. Such currents neither kill the central nervous system outright nor paralyze it instantaneously. Death of the nervous system from such currents is due to the total anemia following a sudden arrest of the circulation.

* The satisfactory results of several preliminary experiments performed at that time, with rather imperfect apparatus for generating oscillatory currents of high potential, appear to indicate that the application of such a current to the fibrillating dog’s heart, in conjunction with the perfusion of the coronary vessels with defibrinated blood (preferably undiluted with saline), very materially hastens the restoration of the coordinated heart beat.
3. In rare instances, when an electric current traverses only the cerebro-cervical portion of the nervous system in considerable intensity and for a considerable length of time, it may kill by asphyxia, consequent to a more or less complete inhibition of the respiratory movements, which occurs chiefly during the passage of the current. No existing facts warrant the conclusion that the medullary respiratory centre is paralyzed or killed in such conditions.

4. Industrial currents are practically non-lethal to frogs and turtles, as the condition of fibrillation quickly and spontaneously disappears from their hearts after the current has ceased to pass. Such animals, of course, can be killed by the very prolonged application of a current of moderate intensity, or by one of enormous voltage and large intensity.

5. Strong electrical currents applied to the surface of the skin affect the heart in the same manner as currents of less strength do when they are applied directly to the exposed heart.

6. It may be possible for an electric current of enormous intensity and electro-motive force to produce instantaneous death either by its disruptive action or by producing an instantaneous heat coagulation of the cellular constituents of the body. Industrial currents do not kill instantly, although as a result of their action death rapidly occurs. The experiences of individuals who have recovered from severe electric shock indicate that such a mode of death is not a painful one.

7. Spontaneous recovery of the dog's heart from fibrillation produced by strong currents is rare. Spontaneous recovery of the dog's heart from fibrillation and restoration of the arrested circulation after the external application of a strong current for two or three seconds appears not to exist.

8. Artificial recovery of the excised dog's heart from fibrillation induced by the external application of a strong electric current is possible.

9. Artificial recovery of the fibrillating heart of the dog, with restoration of the circulation and recovery of the nervous system, can be accomplished by the method described in this paper, provided the duration of the shock is short and the procedure is begun immediately after the cessation of the current.

A CASE OF FIBRO-LIPOMA OF THE TONSIL.
WITH MICROSCOPIC SECTION.*

BY THOMAS AMORY DE BLOIS, M. D.,
BOSTON.

On the morning of March 8th of the current year a male patient, James Battaglia, appeared at the Throat Department of the Boston City Hospital for treatment.

It was his first appearance, and he merely stated that a kind of a lump had been hanging down in his throat for some time—for several months he had noticed it. He was about forty years of age.

On examination a small tumor, of about the size of an undersized peanut, was seen hanging by rather a thin pedicle, which appeared to grow from a crypt in the patient's left tonsil, near the top.

On my showing this to Dr. Leland, he remarked that I had better jerk it out and see what it looked like, for we neither of us had ever seen anything similar in that locality. I said I would take it off with the loop. This I did. After making two applications of ten-per-cent. cocaine solution, I slipped the platinum loop over and then drew the growth out as much as I could with forceps. I pushed the loop up until it touched the tonsil, and, putting on the current, cut through the pedicle without pain, in two seconds.

The little tumor was sent to the pathological department and several sections were made, one of which I have the pleasure to present to the association, and it is now under that small microscope. I regret to say that the growth itself was lost.

The report from the pathological department states as follows:
S. 99-99.

James Battaglia. Throat Out-patient Department.
Polypoid growth from left tonsil. No subjective symptoms.

Microscopical examination shows a section bounded completely, except for one sixth of its periphery (the pedicle), by dermis. Within is a coarse, irregular network of fibrous tissue, the fibres of which are somewhat separated (edematous), the network bearing, most deeply in the mass, areas of large fat globules.

Anatomical diagnosis, fibro-lipoma.

Lipomata have generally been considered rare growths. Mackenzie (vol. i, p. 93) states that large growths of fibrous structure of fatty tumors have also been met with in the region of the pharynx. Bernard Holt has recorded a case in which a fatty tumor, springing from the left side of the epiglottis and pharynx, hung down into the oesophagus for nine inches; and in two other cases cited it is stated that they appeared to be fibrous. Mackenzie apparently did not come across any.

In de Schweinitz and Randal's symposium, Jonathan Wright states that lipomata have been reported by Farlow in the Transactions of the American Laryngological Association, 1895.

In Burnett's symposium, by Lennox Browne, he quotes Bruns as reporting one case, in 1808, of lipoma of the pharynx.

Moritz Schmidt has seen one case in the pharynx on the upper limit of the posterior wall of the velum.

Those observed on the tongue are rich in fibrous tissue, and then are termed fibro-lipoma.

This gentleman further states that Kuenne has collated forty-nine cases, of which three were in the nose, thirty-six in the mouth, three in the fauces, and seven in the larynx. They are found mostly in old persons, and more in men than in women.

* Read before the American Laryngological Association at its twenty-first annual congress.
Since Kuenne, Duerbeck has reported one on the tongue, and Vergely has reported multiple lipomata of the tongue developing unnoticed by the patient.

DRI Y HEAT OF HIGH DEGREE AS A THERAPEUTIC AGENT.

By C. E. SKINNER, M. D.,
NEW HAVEN, CONN.

Moist heat has been known in therapeutics as a sedative since the dawn of medical science. Its application has been so common and so uniformly useful in relieving pain in some degree that poulticing has been for centuries a routine measure even among domestic remedies for combating local inflammations. But its powers are very limited. Moist heat can not be continuously applied to the skin at a temperature much above 150° or 160° F. without scalding, and this degree of intensity is dissipated so rapidly by the circulation that it fails to penetrate the deeper tissues, and therefore can not produce marked or profound effects.

Dry heat, however, as is well known, can be borne at much higher temperatures—I have used it at 500° F.—with consequently greater penetrative power, if it can be kept dry; but here is where the difficulty has arisen. Heated substances, dry in themselves, induce perspiration when kept in contact with the skin, and when the perspiration has collected for a few seconds the heat, which was originally dry, becomes moist and can not then be borne by the patient.

This problem has recently been solved, however, by using air as the heat medium, and the apparatus made by Frank Betz & Company, of Chicago, has given me results which are extremely satisfactory. I am able with it to secure constant temperatures anywhere up to 500° F.; and that it is well under control is shown by the fact that, although constantly employing these extreme degrees of heat, I have blistered but one patient since I began to use it. I shall cite his case farther on in full (Case V), and therefore will only mention the accident here.

The apparatus consists essentially of an asbestos-lined metal cylinder, open at one end, thirty inches long, sixteen inches vertical diameter, and nine inches horizontal, the air contained in which is brought in contact with the part to be treated by heavy cloth attachments so constructed as to fit the different parts of the body—abdomen, back, shoulder, etc.—and a gasoline or Bunsen gas burner to heat the air contained in the cylinder. A high-temperature thermometer is conveniently placed for registering the degree of heat obtained. Dryness of the part being treated is maintained by wrapping it closely and smoothly in four or six thicknesses of loose-meshed Turkish toweling, which absorbs the perspiration as fast as it is excreted. The high temperature of the air which permeates the toweling immediately vaporizes the moisture absorbed therein, which diffuses into the air contained in the cylinder. A loosely meshed quality of toweling should be used, because the heavier, tightly woven grades hinder this diffusion, thus retaining the steam and superheated perspiration in that portion of the wrapping next the skin so long that blistering or scalding is liable to occur.

It is necessary to change the air in the cylinder with sufficient frequency to prevent its saturation with the vaporized perspiration reaching a point where free, rapid interchange of vapor between it and the wrappings would be interfered with, and this is provided for by a valve in the top. Opening this permits the moisture-laden air to escape, and its place to be taken by a fresh supply which enters through an opening in the bottom by which the heat from the burner is applied. The air is thus heated at the same time that it is introduced. It has become my custom to change the air about once every ten minutes, but the interval will vary according to the weather and the idiosyncrasies of the individual under treatment as to the quantity of sweat which he excretes. On very damp days, and when the patient perspires easily and freely, it will require shortening, because the greater percentage of humidity already existing in the air introduced, or the greater amount being thrown off by the patient, will cause the point of excessive saturation to be reached more quickly than on dry days, or with a "dry" patient, and vice versa.

When excessive saturation does occur, the patient will quickly inform you that "it is burning me." Under these circumstances time should not be lost in waiting for the opened valve to effect the necessary change of air, because if that "burning" is not immediately relieved it will increase rapidly to an excruciating intensity, and scalding is liable to follow which will render the parts extremely sensitive for many hours, but the attachment should be removed from the cylinder and the supersaturated air allowed to rush out at once. Meanwhile introduce the hand into the cylinder, press the toweling intermittently down upon the part complained of, and when the burning sensation has passed away replace the attachment and use the valve more often thereafter. This "burning" sensation is also caused by another condition—viz., a failure to secure even and complete contact of the toweling and the skin, as when a wrinkle forms. Perspiration collects on the area of skin not in contact with the absorbent, its temperature rapidly rises toward the boiling point, and blisters if not removed. It is particularly well to bear this in mind in reference to the toes when treating the feet, as most people unconsciously wriggle these members and disarrange the wrappings. Pressing the separated toweling down upon the suffering area of skin produces immediate absorption of the boiling sweat and relief.

My experience thus far has led me to conclude that
the most satisfactory results follow treatments which last at least one hour, with a degree of heat not less than 350° F.; but it is necessary to continue the treatment long enough and push the temperature high enough for the patient to feel that the agent has penetrated right down to the sore spot. He must feel that it is being "touched" by the heat, whether it takes one or two hours and 350° or 500°. It is unnecessary to say that keeping the parts at rest is a vast help in overcoming their disability; but, as will be seen later, abeyance of function is not always a prime necessity.

Although somewhat cumbersome, the apparatus can be transported to the patient's bedside by having a suitable cabinet made to contain it, a point of importance in view of its usefulness in some acute diseases which will be mentioned later. For heating I use illuminating gas through a Bunsen burner in my operating room, and prefer gas under all circumstances; but in some houses the flow of gas is not strong enough and in some others there is no gas at all, so that the gasoline attachment becomes a necessity in treating many patients at their homes.

Although dry hot air has been with us but a short time, it has proved itself a therapeutic agent whose value cannot be overestimated, and I know of no measure or remedy which can fully take its place. My experience with it extends over the past year, and in combating the conditions in which I have ascertained it to be indicated, speculation as to the result has long ceased to be an annoyance. Its almost uniform success justifies a strong belief that its future is pregnant with happy possibilities, but it needs study and development. For the relief of pain in accessible parts it has no equal, and it accomplishes this beneficent result without any disagreeable or deleterious effects either at the time of application or subsequently. Under its influence the pain simply grows less and less, the patient quieter and quieter, until in from fifteen to thirty minutes it has entirely disappeared. I have had my attention arrested by a gentle snore from a patient under treatment who, half an hour before, and for twenty-four hours previous to that, had been writhing in constant agony (Case VI.) The pain always returns after some time, the period of relief varying from four to fourteen hours; but the recurrence is ordinarily less severe than before and is controlled just as easily as at first. The heat may be applied as frequently as the pain returns, and this can be kept up indefinitely.

The agent we are considering has in my practice most frequently found a field for usefulness in rheumatism, and, so far as I have been able to ascertain, this is also the experience of others. The reason for this can probably be found in the fact that rheumatism is a very common disease, an extremely painful disease, and not infrequently a most exasperatingly obstinate disease, a combination of characteristics sufficient to prepare a warm welcome for any new measure which promises better results than those ordinarily attained. I have been specially interested in the disease for several years, and I was in the hope of increasing my ability to cope with its intractable aspects that I first investigated this element of treatment. The palliating influence of mild degrees of heat on the pain in this disease is a matter of common knowledge, and I have frequently had mechanics with rheumatic shoulders, backs, or hips tell me that a common practice with them on arriving at the shop, before going to work, was to heat the complaining part by leaning against a steam pipe. The procedure would give them considerable comfort. If this low degree of heat was helpful, a very high degree might give strong results. As we shall see, the inference was confirmed by subsequent experience.

I will say here that I have never observed that hot air, relied upon alone to the exclusion of drugs and dietary regulation, particularly in the matter of alcoholic beverages, possessed any radically curative effect upon this disease. Temporary relief from pain seems here to be its limit, unaided. The case needs to be cared for just the same in every way as if hot air were not being used at all. What it does appear to do, aside from relieving the pain, is to induce a metabolic activity in the tissues affected by reason of which remedies act with greatly increased power, and, which is of as much if not more importance, with certainty. Their effects rapidly become apparent upon the patient and recovery of the suffering structures proceeds in a uniform and progressive manner, which is most gratifying after having watched the case stand most annoyingly still or grow worse for two or three weeks.

I have selected the following cases for citation as being strongly illustrative of what hot air will do in rheumatism. Antirheumatic drugs, selected according to indication, were administered in every case synchronously with the hot air, but, as the drug treatment of the disease does not come within the scope of this article, I shall mention them only when force of illustration demands it:

**Case I. Acute Inflammatory Rheumatism.**—I was called to see Miss A. F., sixteen years of age, November 25, 1898. For the preceding four days she had been suffering with severe pains in the left ankle and great toe joint, which had increased rapidly in intensity during the preceding twenty-four hours. Had been unable to get any sleep or rest the preceding night. Great toe joint was much swollen and exquisitely tender to touch; ankle slightly swollen, but very sensitive. Patient had sustained a severe attack of inflammatory rheumatism ten years before, which had involved the cardiac valves, and she had carried the murmurs up to within six months before this time. Both parents were rheumatic. Hot air was applied that afternoon. In fifteen minutes the pain had disappeared entirely, and for the first time in forty-eight hours the patient was comfortable and resting quietly.

**November 26th, P. M.—**Patient slept all night. Pain returned at intervals, but only as slight twinges.
Swelling in ankle has entirely subsided; it is nearly gone from great toe joint, and the patient is limping about with a slipper on. Considerable soreness still exists in the parts when manipulated. Hot air administered again. In view of the marked improvement manifested I decided to discontinue the treatments, and requested the patient to report at my office in two days if able to walk, and to let me know if anything went wrong in the meantime.

24th.—Patient called at my office, reporting that she had had no pain since last treatment. Soreness had entirely disappeared on the day following it, and she had been out walking with her shoes on as usual. This patient required but two treatments and was entirely well in three days, being the shortest case on my record.

Case II.—A man, forty-five years old, whom I was asked to see February 28, 1899. He had had inflammatory rheumatism off and on all his life, but the last attack preceding this one had occurred in 1891, at which time he was ill for three months, both ankles and the right great toe joint being involved. His father had suffered frequently and severely with inflammatory rheumatism and his mother was gouty. When I was called he had been suffering for two weeks, the left hip being the part involved, and during this time he informed me that he had been taking salophen and alkali thia constantly, with no result. The symptoms had increased rapidly during the preceding two days, and he had had no sleep for twenty-four and very little for forty-eight hours. Joint was extremely sensitive to manipulation and pressure. Hot air was applied and pain was entirely gone in twenty minutes. At conclusion of treatment the joint could be manipulated within certain limits with so little discomfort that I conceived strong hopes of having encountered another case like the foregoing, and requested the patient to call at my office the following morning if he was able.

To my gratification, he appeared at the time appointed, March 1st, reporting that he had experienced no pain after the treatment of the preceding day until this morning on arising from bed, but that since then it had been slightly but constantly present. Patient was on his way to business, and had "only dropped in to let me know that he was about all right." I persuaded him to allow me to treat him again, but he would not relinquish his intention of attending to his business. I treated him for an hour, with entire relief of pain as before, and he promised to report the next day.

March 2d.—Patient called this morning, informing me that half an hour after leaving my office yesterday he had suffered from an acute attack of pain, lasting about ten minutes, which had then subsided, and he had felt it no more until this morning, when for half an hour it was quite severe. Another demonstration as to his continuing to perform his business duties was met by the assertion that to stop at this time would entail financial loss that he was unwilling to sustain, and that as long as he continued as comfortable and free from pain as he was then he would rather keep about his business and take a longer time for his recovery. He was treated and requested to report the next day.

3d.—No pain since last treatment, but feels a dull soreness in parts, which is growing steadily less. Hot air was again administered. Patient desired to stop his salophen, but it is unnecessary to say was ordered to continue. He did not call again until March 8th. when he reported having had slight twinges of pain always in the morning on rising and occasionally during the day, but of steadily decreasing severity since the last treatment. This morning, for the first time since the attack began, he had been entirely free from pain of any sort. He laughingly derided my having desired to keep him in bed and said, as I supposed in joke, that he wasn’t "going to take any more of those powders."

11th.—Patient continued to feel so well after his last call that he had carried out his threat of stopping the salophen, and yesterday he began to suffer again. Resumed salophen, and toward evening grew more comfortable, but this morning pain is again quite severe. Hot air gave it customary immediate relief, but patient was going out of town and could not call again for treatment until two days after.

13th.—Reported freedom from pain all day on the 11th, but it was present considerably yesterday and this morning. Hot air administered with the usual happy results.

14th.—Slipped on a carstone while running to catch a car yesterday, wrenching the affected hip badly. Suffered excruciating pain for an hour, which then subsided, leaving intense soreness and throbbing, which are present this morning. Treated with hot air, but pain, for the first and only time, was not entirely relieved, and patient left my operating room with a slight limp.

15th.—Appeared at my office at 7.30 a.m., reporting that pain returned quite severely four hours after treatment, and has staved with him pretty sharply ever since. Insists that he cannot leave his business and remain quiet at home, and I suggested that he be treated three times to-day, to which he consented. I treated him at 9 a.m., at 2 p.m., and at 7 p.m., with the result that he kept about his business and had practically no pain.

16th.—Came to my office at 9 a.m., reporting that he had had no pain until eight o’clock after rising from bed, and then only slight dull twinges. Administered hot air at 9 a.m. with the usual satisfactory result, and requested him to call again for treatment at two in the afternoon. He did so, informing me that he had had no pain at all since morning, and expressed himself as feeling better generally and locally than at any time since the attack began. Ordered him to come again in the evening if he felt the slightest return of the pain. I did not see him again for a week.

On March 23d he came to my office early in the afternoon, supporting his right arm with his left, suffering intensely in his right shoulder, which he said had commenced about 11 a.m. The slightest movement of the affected joint forced him to cry out with pain, and when I had succeeded, with great difficulty and the utmost care and gentleness, in removing his clothing preparatory to treatment, he was shaking like a leaf. I applied hot air with the usual result. Pain was relieved in ten minutes. At the end of the treatment he could move his arm sufficiently to get into his clothing without assistance, was perfectly free from pain, but could not raise his elbow to within more than three inches of the level of his shoulder. He had had no trouble with the hip since last treatment, and I will say here that the recovery of the joint was complete, and remained so.

I directed him to call again for treatment in the evening. At that time he was suffering slightly, but was able to remove his clothing for treatment without assistance.
Hot air was administered and directions were given to call again next morning if he was in any pain at that time. I did not see him again until March 25th, when he called to tell me that he had had some slight twinges of pain during the night following the last treatment, but had remained free from it ever since. I requested him to call immediately if any more symptoms appeared, and to continue the salopphen for two weeks. Five days afterward, on March 30th, he called, complaining of a dull sickening ache in the right shoulder, which I dissipated with one treatment, and that was the last of the trouble.

This case is very instructive. It illustrates forcibly the remarkable power of hot air in rapidly alleviating rheumatic pain; it emphasizes the necessity of accompanying the treatments with internal medication, as shown by the severe return of symptoms in the same old place on March 10th and 11th, after the salopphen had been prematurely discontinued; and when we consider that the total length of time during which this patient was under treatment—viz., one month—is far longer than the period required for the recovery of any other case of acute rheumatism which I have submitted to this treatment, I consider that it exemplifies in a very gratifying manner the power of hot air to shorten the duration of the disease. Here was a case in active eruption in a man of a strongly rheumatic diathesis, who kept up and about his business all the time, and yet in spite of this utter and constant disregard of one of the prime essentials to be secured in the treatment of inflamed joints—viz., rest—the attack was extinguished completely in one short month. Not only that, but the patient has been kept entirely free from pain the vastly greater part of the time during that month, an achievement which could not be claimed for any other treatment with which I am acquainted, however perfect may have been the rest secured. There is no question in my mind that the attack would have ended much sooner if I could have kept him quiet.

(To be continued.)

ALCOHOLISM.

By CHARLES J. DOUGLAS, M.D., BOSTON.

There are few chronic diseases that will more surely yield to proper medical treatment than alcoholism. Proper treatment can be given, however, only when the patient has been removed from his home and customary surroundings. Any practitioner who has attempted to treat alcoholics at their homes will admit that it is practically impossible to more than temporarily relieve such patients. Still, a removal may be made that will be to the patient’s disadvantage. Confinement in a jail is worse than no treatment at all, and an insane asylum is almost as objectionable. The so-called “homes” for inebriates are another class of worse than useless institutions, in which an intoxicated man is thrown into a cell and allowed to rave without stimulants till sober, or till death relieves his suffering. A humane man would not treat a dog with such barbarity. The sudden withdrawal of alcoholic liquors in this way not only causes the patient intense suffering, but, after a protracted spree, is the principal cause of delirium tremens and death. The withdrawal of alcohol should be gradual, its place being temporarily taken by such remedies as hydrastis or capsicum, or other indicated remedies. I have followed this course for years in the treatment of many hundreds of alcoholics, and my cases of delirium tremens never go beyond the first symptoms, and I have never had a death. To successfully treat alcoholism the patient should be removed to a sanitarium where the treatment of such ailments is made a specialty. Here he can be under the constant care and observation, day and night, of physicians and attendants whose special training and experience enable them to adopt the best methods in the management of the changing conditions of this peculiar disease. Fortunately, there are now sanitariums of this kind in many parts of the United States. I, of course, do not here have reference to the quack “cures” in which secret nostrums are dispensed in a routine way by a physician who knows nothing of their composition. No self-respecting practitioner can take his patients to such an institution. But I refer to sanitariums that are ethically conducted, to which a physician can take his alcoholic cases and receive any information he desires regarding the remedies employed in the treatment of his patients, and where he will be cordially welcomed as a consultant by the house physician.

In treating of the pathology of this disease it is customary to enumerate the abnormalities found in the stomach, liver, bowels, kidneys, etc. But the disease of alcoholism stands quite apart from these ailments. The patient may or may not have gastritis or enteritis or nephritis, but in all cases he will have an abnormal condition of the nervous system that produces either a perpetual or a periodic demand for the drug action of alcohol. Hence alcoholism per se is a disease of the nervous system. He who can drink moderately without ever becoming intoxicated may have the drinking habit, but he has not acquired the disease. This, however, does not prove that he possesses superior intelligence or will power. It only indicates that his nervous system is less susceptible than others to the poisonous action of alcohol. It is purely a physical difference that distinguishes the moderate drinker from the helpless drunkard. Professor Atwater’s dictum that two ounces of alcohol a day is a food, and more than that is a poison, may be true in some individuals, but as a statement of universal law it is absurdly false. I have a patient now under treatment to whom two ounces of alcohol is such an active poison as to transform him from a clear-headed business man into an irresponsibl-
The etiology, symptoms, and diagnosis of alcoholism are well known, but its treatment deserves far more attention than it has ever received. The advice given in some text-books appears to be of a purely theoretical character, unsupported by sufficient practical experience. Much of it is certainly very erroneous. In the acute stages, sleep and nourishment are of the first importance, especially if the patient has been on a protracted spree, or is showing signs of delirium tremens. If the stomach is too weak to retain more substantial food, an excellent aliment is hot malted milk. But the best food in this stage of the disease is eggnog, if the stomach will retain it, and it usually will. Beat up one egg in a tumbler, nearly fill the glass with milk, and add one or two ounces of whisky. Sugar may be added if desired, but sweets are usually distasteful to a patient in this condition. I believe this combination to be the *ne plus ultra* of foods in acute alcoholism. In many cases, however, the patient refuses all nutriment till after he has been made to sleep.

A very satisfactory hypnotic in this disease is a mixture of bromide of potassium and chloral in equal parts. This should be given in several small doses, the effect of each dose being carefully noted. Of the coal-tar products trional is the best hypnotic, but it must be given in large doses. Suggestion, as practised by the school of Nancy, is occasionally useful in promoting sleep. I never use morphine unless there is some unusual complication.

There is, however, one harmless remedy that will produce sleep in a few minutes, even when the patient is suffering with the wildest delirium. That remedy is apomorphine. I inject subcutaneously just enough to produce slight nausea, but not enough to cause vomiting. One thirty-fifth of a grain is the average quantity required, but individual susceptibility to this drug greatly varies. In a few minutes after administering the remedy perspiration appears and the patient voluntarily lies down, when a sound and restful sleep immediately follows. This sleep lasts at least an hour or two, and, if other sedatives are previously given, it will usually last six or eight hours. The use of apomorphine in this manner and for this purpose is, I believe, original with me. While its value has remained so long unrecognized by the profession, yet in point of fact there is no hypnotic in our materia medica that is at once so prompt, so safe, and so sure. It is of special value in all forms of mania, regardless of the cause. It may also be given in full emetic doses in many cases of alcoholism with marked benefit. I have frequently had such patients express gratitude for the great relief afforded by this emetic. It seems to frequently act as almost a specific in relieving the alcoholic craving.

After the patient has recovered from the acute symptoms, he should have a course of tonic treatment covering a period of several weeks. The limits of this article will not permit a discussion of all the remedies that should be employed in the varying states of this erratic disease. An excellent one, if properly and judiciously used in connection with other remedies, is the nitrate of strychnine. It may be given, however, in much smaller doses than the text-books usually recommend. Potter, in his *Materia Medica*, advises the hypodermic use of this remedy. He says: "It removes the craving for stimulants, counteracting the vasomotor paralysis, to which most of the injurious effects of alcohol are due, and is probably in other respects a true antagonist to the action of that narcotic poison on the human system."

Dr. Portugaloff, of Russia, under date of September 2, 1891, writes as follows: "I have first and foremost to state that the use of strychnine in the treatment of alcoholism is no discovery of mine. In all the articles I have ever written upon the subject I have always pointed out that the credit of the discovery belongs to the English and French doctors, Luton and Dujardin Beaumetz. Convinced that all forms of drunkenness are but forms of disease, with perhaps a basis of vice, I have, during the period of five years, treated about five hundred patients suffering from different forms of alcoholism by hypodermic injections of strychnine. I do not order the patient at once to discontinue drinking. I prefer that he should voluntarily leave it off, and that alcohol should become distasteful to him. Then I have cases of relapse—patients who once a year return to their old bad habits, but who, on such occasions, always come to me for a repetition of the treatment, which invariably sets them right again for another year. I always felt sure that if in obstinate cases the patient could be isolated, and all possibility of obtaining alcohol removed—which would be easy in a "sanitarium for inebriates"—cure would certainly follow."

There are several reasons why the hypodermic method here recommended by Dr. Portugaloff and Dr. Potter is preferable to the administration of remedies exclusively by the mouth. The stomach is less burdened by drugs. The remedy goes directly into the circulation without being subjected to the action of the digestive fluids. The dosage can be regulated with great accuracy. The remedial action is more prompt. It brings the patient face to face with the physician several times a day.

It is remarkable how few physicians know how to properly give a hypodermic injection. It should not hurt nor scarcely be felt by the patient. It should never produce an abscess. It should not produce a temporary subcutaneous swelling. The operation should be performed so quickly that five can not be counted between the insertion and withdrawal of the needle. The physician who fails in any of these respects has not yet learned the art of administering a hypodermic injection.

As early as the sixteenth century gold was recom-
mended as a remedy for alcoholism, and recently extraordinary virtue has been alleged for it. I have not, however, found that it possesses the marvelous properties attributed to it by the public, although it is probably not devoid of merit.

One or more of the bitter tonics should be employed during the entire period of convalescence. With good appetite and digestion and restful sleep the patient will rapidly improve. The aim of the entire treatment should be to build up his general health, so that when he returns to his home he will be in the best possible condition.

Cheerful and hopeful surroundings, in the company of others who are under similar treatment, are conditions of great value. It is desirable that an earnest and purposeful spirit should be cultivated. It has been our custom for several years at our sanitarium here in Boston to begin each day with a simple service of songs and reading, lasting about ten minutes. I consider the esprit de corps of a properly regulated sanitarium is of great importance in the treatment of this disease.

The rescue of humanity from the physical, mental, and moral ruin resulting from alcoholism and other drugaddictions devolves not upon the moralist but upon the physician. This is the medical man’s burden, and the enlightenment of the future will hold him responsible if he does not earnestly take it up.

REPORT OF A CASE OF ABSCESS ON THE ANTERIOR SURFACE OF THE EPIGLOTTIS.

BY ALEXANDER C. HOWE, M.D.,
ASSISTANT SURGEON TO THE NOSE AND THROAT DEPARTMENT, MANHATTAN EYE AND EAR HOSPITAL;
SURGEON TO THE NOSE AND THROAT DEPARTMENT OF THE WILLIAMSBURG HOSPITAL.

Bosworth states that perichondritis of the epiglottis does not result in an abscess with necrosis, but in an ulcerative action.

The unusual condition of abscess of the anterior or superior surface of the epiglottis presented itself in a young man of twenty-four years of age, a laborer, undersized and not very well nourished. He complained of pain and tenderness just above the larynx and a rapidly increasing dyspnea. Soresness of the throat had begun about a week before I saw him. He had had slight chill, headache, and malaise. During the three preceding days he had been unable to eat, as deglutition was extremely painful. A rapidly increasing dyspnea had distressed him so greatly that the preceding night he had been unable to lie down.

Inspection showed fauces and pharynx slightly inflamed. The epiglottis was forced backward and down so as to almost completely close the opening to the larynx. Inspiration was more difficult than expiration, as the former drew the epiglottis down more closely over the orifice. This position of the epiglottis was caused by a well-defined rounded tumor about half an inch in diameter occupying the middle of the anterior surface of the epiglottis and extending almost to the tip. This tumor pressed on the slightly inflamed and hypertrophied glands on the base of the tongue. There was considerable swelling, redness, and congestion in the surrounding parts. The interior of the larynx could not be seen at this time, but when it came in view two or three days later there was nothing to cause the dyspnea. As it was, respiration was relieved somewhat by extending the tongue. Pressure upon the tongue increased the pain and dyspnea.

The tumor was incised and nearly a dram of yellow, foul-smelling pus was discharged. Dyspnea was greatly relieved at once, and the other symptoms began to rapidly subside. Probing indicated that the cartilage was somewhat destroyed, but not sufficient to perforate it. After healing, the surface was dimpled and the lateral curvature flattened and the tip bent forward. In about ten days the epiglottis had returned to its normal position. The patient gave no history of rheumatism, excessive drinking, or eating of hot or irritating foods. He, however, had been subject to slight sore throats during cold weather, but never had experienced a similar attack.

The case proves conclusively that perichondritis does result in abscess and necrosis of the cartilage of the epiglottis.

PALATABLE QUININE MIXTURE FOR CHILDREN.

BY W. J. GREANELLE, M.D.

HAVING had occasion to prescribe quinine repeatedly for young children, and being dissatisfied with the combination with syrupus yerbe sante, I have made a number of experiments with a view to obtaining a pleasant and acceptable quinine preparation which could be continuously administered to children without their objection.

I give below the details for the preparation of a "child's quinine mixture" which I find not only to be readily taken by children but also serviceable as a bribe to be given after unpleasant medicines, such as stronger solutions of quinine.

The mixture is designed as a tonic and malarial prophylactic for children living in malarious sections. It will serve for active medication in acute cases of malarial disease in children of three years or younger by giving the larger dose at hourly intervals.

I find that children literally cry for it, and that it has frequently served as an excellent bribe, to be given immediately after a simple solution of quinine hydrochloride in water when large doses of the drug are neces-
A teaspoonful of water carrying two or three grains of quinine muriate will be readily taken by any child, with "a spoonful of pink medicine right after." Those who have little patients in large numbers will appreciate this.

(1) \( R \) Quinine hydrochlorate ... gr. v-gr. x; 
    Alcohol ...................... 5j.

M.

(2) \( R \) Oil of cinnamon, \[ \{ \text{each.. ml xxx-xl} \]; 
    Magnesia ..................... q. s.; 
    Water ........................ 5j.

M. Let stand for some hours; filter.

(3) Mix 1 and 2 and add—
    Simple syrup ................... 5ij;
    Carmin or cochineal solution.. gtt. v.

Dose, one or two drachms, as directed.

Saccharin in small quantity helps to disguise the larger dose of quinine.

Small doses of Fowler’s solution may be added, if indicated, or sodium bromide for children made irritable by quinine.

Druggists will make this in quantity and keep it in stock if requested. It is simple, easily made, and inexpensive. Moreover, children like it.

University Heights.

Therapeutical Notes.

A Clyster for Convulsions.—Riforma medica for August 1st ascribes the following to Simon:

\( R \) Musk ..................... 3 grains;
    Camphor ........................ 15 “
    Hydrate of chloral ..... 7½ to 22½ “
    Yolk of one egg;
    Water ........................ 1,500 “

M. To be taken at one time.

Paraform for Warts.—Meuse (Dermatologische Centralblatt, April; Medical Review, September) recommends paraform for the treatment of warts on account of its penetrative power. He has also used it in papular syphilides and in psoriasis palmari. The drug is made up with collodion (ten per cent.). Usually after two or three days the epidermis peels off.

Strontium Bromide and Iodide.—Gillespie (cited in the Klinisch-therapeutische Wochenschrift for September 3d), who finds these compounds far less apt to produce toxic effects than the potassium salts, gives the following formula:

\( R \) Strontium bromide .......... 6 parts;
    Strontium iodide .............. 12 “
    Distilled water ............. 40 “
    Peppermint water, \{ each .. 20 “
    Syrup of peppermint, \}

M. S.: A teaspoonful three times a day.

Aspidium Spinulosum as a Teniaicide.—Aspidium spinulosum so closely resembles Aspidium filix mas, the official male fern, that some botanists think the two plants should be looked upon as constituting but a single species. The first-mentioned variety is much more abundant than the official plant in some districts, and Lauren (Therapeutische Monatshefte, April; Fortschrift der Medizin, September 6th) recommends the use of an ethereal extract of its rhizomes as a remedy for tapeworm, in doses of from forty-five to sixty grains. He adds that it has long been employed in Finland, and that it may be had by Merek, the Darmstadt chemist.

Antispasmodic Draught.—Riforma medica for August 16th gives the following:

\( R \) Alcololate of aconite \{ of each, 10 drops;
    Tincture of belladonna,
    Cherry-laurel water .......... 150 grains;
    Orange-flower water .......... 900 “
    Croton tiglium water .......... 300 “
    Syrup .......................... 450 “

M. A soupepoonful hourly.

A Mixture for Excessive Acidity of the Stomach.—

The Settima medica for August 5th gives the following formula:

\( R \) Sodium sulphate, \{ each ....... 30 parts;
    Sodium chloride, \{ “
    Calcium sulphate ............ 5 “
    Sodium carbonate ......... 25 “
    Sodium borate ............. 10 “

M. A coffee-spoonful three times a day, before eating.

The Treatment of Epistaxis.—Range (Wiener medicinische Blätter, August 17th; Klinisch-therapeutische Wochenschrift, September 3d) calls attention to the fact that the source of the hemorrhage is almost always quite limited and situated well forward. When this is the case, compression suffices to stop it. In addition, one may inject a five- to ten-per-cent. solution of gelatin in artificial serum, or apply tampons wet with such a solution. If it is found necessary to plug the posterior nares, the tampon should not be left in place for more than twenty-four hours.

For Syphilitic Alopecia.—Riforma medica for August 23d ascribes the following to Goacher. The hair should be kept short, and frequent applications of the following lotion made to the head:

\( R \) Corrosive sublimate .......... 3 grains;
    Hydrate of chloral .......... 60 “
    Resorcin ............. 30 “
    Castor oil .......... 15 “
    Alcohol at 90° .......... 3,000 “

M. At the same time friction should be made with the following ointment:

\( R \) Calomel .......... 45 grains;
    Vaseline .......... 900 “
    Salicylic acid .......... 9 “

M. Or the following:

\( R \) Precipitated sulphur .......... 45 grains;
    Vaseline .......... 900 “

M. This latter ointment is to be prepared when the alopecia is accompanied by seborrhoea and pityriasis of the hairy scalp.
THE NEW YORK MEDICAL JOURNAL.
A Weekly Review of Medicine.
Published by D. Appleton and Company. Edited by Frank P. Foster, M.D.

NEW YORK, SATURDAY, OCTOBER 28, 1899.

AN ATTACK ON THE OCULISTS OF NEW YORK.

In our department of Miscellany we reproduce from last Saturday's Evening Post an article that seems to call for comment. We print it under the heading which serves also for this article, but the Post saw fit to give it these headlines: Oculists' Commissions. A Secret Division of Opticians' Profits. Serious Charges by One of the Latter—Excessive Cost of Glasses to Poor Patients—Cases Cited to Prove the Accusations. Almost the entire article is a quoted declaration purporting to have been made by "a prominent Maiden Lane optician," but the opening sentence is the Post's own statement that "there is a tacit understanding between some practitioners who 'give their services free' at the free ophthalmic hospitals and certain opticians for the division of profits on the glasses prescribed by one and sold by the other to the indigent patient." The Post may think that its use of the expression "some practitioners" clears it of any charge that may be made to the effect that it has brought an unwarrantable accusation against that large body of honorable men, the junior oculists of New York, for it is about them that the anonymous optician harangues, since he says that "the leading professors at these free institutions are salaried and above the taint of reproach in professional ethics." If the Post does entertain any such view in justification of its own course, we think the medical profession in general will not consider the loophole as wide enough to acquit the paper of the charge of having decked out a trumpery slander with headlines and an introductory statement calculated to injure many young medical men in the eyes of the public.

We cannot deny that there are black sheep in the medical profession. They exist among all classes of men. We have no knowledge that there is on the staff of any hospital in New York, ophthalmic or of any other character, a man so low as to conspire with tradesmen to fleece the poor, but we can not say that there is not. This much, however, we have no hesitation in saying, that if such a man's dishonest acts were to come to the knowledge of his professional brethren he would be dismissed from his place and ostracized at once. We feel warranted in affirming, further, that such practices as the Post implies are common, if they are resorted to at all, are so rare as to constitute but the exception that proves the rule of the uprightness of physicians in their dealings with the poor. As for the "prominent Maiden Lane optician's" statements, they bear internal evidence of inaccuracy in the sentence we have already quoted, to the effect that "the leading professors" are "salaried." Unfortunately, that delusion is general among the poor and prevails to some extent among the community at large, and it works to the discredit of the profession. We do not need to say—for all our readers must know it—that the men to whom the optician has reference are not "salaried." This "prominent optician" professes to be interested in a movement to detect and expose individual instances of the vile practice which he says is general. Let him do that and he will be regarded as a benefactor to the medical profession, but he will accomplish nothing but mischief by wholesale allegations such as those to which the Post devotes almost a column of its space.

THE MEDICAL CARE OF OUR FORCES IN THE PHILIPPINES.

It was to be expected that the new secretary of war would promptly enter upon vigorous and judicious measures for suppressing armed opposition to our domination in the Philippine Islands, and that he would show adequate appreciation of the vital importance of a sufficient corps of medical officers having all needed assistance in the way of nurses, hospital stewards, and field helpers, together with ample hospital accommodations, abundant supplies, and sufficient means of transporting the sick and wounded. These expectations are quite fulfilled, according to press reports from Washington. A correspondent of the Sun lately sent to that paper a dispatch giving the substance of an interview with Secretary Root in which the secretary gave evidence of having given very detailed consideration to the provisions for the medical needs of our men in the Philippines.

It appears from Colonel Woodhull's reports that the hospitals are not now overcrowded; there are accommodations for over 2,000 patients, and only 1,847 beds are occupied, including those of convalescents. But this margin, which would appear narrow in the season of regular campaigning, is to be vastly increased to meet any possible requirements that the active operations contemplated on the subsidence of the floods may involve. Provision for the care of 8,000 sick and wounded is well under way, and the transports have taken
EDITORIAL ARTICLES.

Few white Fortschritte may generous article and ships Missouri and Relief, now on their way to Manila, are to be used as floating hospitals. Together, they will accommodate 600 patients.

In the matter of nurses, too, the government is not lagging. Some weeks ago we expressed our confidence that Colonel Woodhull's requisition would be honored, and so it turns out. Thirty women nurses will sail from New York in a few days from now. That was the number that Colonel Woodhull asked for, together with twenty medical officers, but he is reported to have added: "Can use twice as many." Thirteen commissioned medical officers and forty acting assistant surgeons were already either on the way to the Philippines or under orders to proceed thither, in addition to the medical officers of the volunteer regiments. Colonel Woodhull's hint, "Can use twice as many," applies, we take it, to the nurses as well as to the medical officers, and we do not doubt that more women nurses will be sent in time to be of service when hostilities have been carried far enough to make them really needed.

CHLORETONE AS A HYPNOTIC AND ANAESTHETIC.

The hypnotics, analgetics, and anaesthetics of recent years are certainly many, but they can not become too numerous, for each one seems to have some distinctive advantage of its own, making it the most eligible under certain circumstances. One of the newest ones is chloretone, concerning which there is an important article in the Journal of the American Medical Association for September 23d, by Dr. E. M. Houghton, of the Detroit College of Medicine, and Dr. T. B. Aldrich, late of the Johns Hopkins University. The substance of which the authors treat is known by several names, but they have chosen to call it chloretone to distinguish it from acetone chloroform (chloroform made from acetone). Following Willgerodt, they give it the formula $\text{CCl}_3\text{C}-\text{OH}$, and explain that it is $\text{CH}_3$ formed when caustic potash is added slowly to a mixture of equal parts by weight of chloroform and acetone, and is a white crystalline compound of a camphoraceous odor.

Thus far the authors' use of chloretone has been only experimental, but it has extended over a period long enough to enable them to speak of its action with a considerable amount of authority. They have given it by the mouth, by the rectum, beneath the skin, by intravenous injection, and by injection into the peri-tonal cavity, also by confining the subject of the experiment in a tight box where it was compelled to inspire air impregnated with the vapor arising from the drug, and they find that it is capable of producing all degrees of hypnosis up to complete anaesthesia, lasting from a few hours to several days, according to the amount of it that is absorbed into the system. Like all other drugs of its class, it is not devoid of dangerous properties; excessive doses prove fatal.

Besides its action on the central nervous system, chloretone is of decided value as a local anaesthetic, resembling cocaine in this respect, and the small amounts required to produce insensibility of a part are quite harmless. In cases of lacerated wounds, burns, and other injuries of a painful nature it is very efficacious in allaying pain when the injured part is bathed freely with a watery solution. It has been found valuable, too, as an antineptic, and the authors suggest that it may be found useful in preventing or controlling seasickness and the vomiting of pregnancy. As much as sixty grains has been given in a single dose without producing untoward symptoms, but from six to twenty grains, followed by a drink of water or milk, seem to be quite enough to produce the desired results. The authors hint that chloretone may prove a useful general anaesthetic when administered in large doses, and that, given before the administration of ether or chloroform, it may prevent the annoying vomiting that so often occurs when a patient is anesthetized.

ALCOHOLISM AND THE FUNCTION OF LACTATION.

A new evil of alcoholism seems to have been unearthed by Professor von Bunge. At the recent annual meeting of the Union of Abstaining German-speaking Physicians (Deutsche Medizinal-Zeitung, September 25th) he presented statistics which, while he did not consider them as conclusive, showed a remarkable correspondence between the prevalence of habitual tipping among women and their inability to nurse their children.

THE TREATMENT OF INSOMNIA.

Impairment of the normal ability to sleep, often amounting to protracted and exhausting insomnia, not only gives rise to much distress, but also undoubtedly aggravates the trouble on which it generally depends, neurasthenia. Wunderlich (Sammlung klinischer Vorträge, No. 239; Fortschritte der Medizin, September 20th) thinks that two thirds of all cases of nervous insomnia are due to neurasthenia. In its treatment, he properly insists, hypnotic drugs should be avoided as far as possible. He thinks trional and sulphonal are the best of them. Under no circumstances should the use of morphine be allowed. If drugs are to be used at all,
it is generally best to prescribe the bromides in diminishing doses, beginning with forty-five grains at bedtime. If, however, there are phenomena of sensory irritation, perhaps antipyrene, lactophenine, or phenacetine may also be indicated. That form in which the sleep is broken often depends on excessive gastric secretion and acidity of the gastric juice; for this sodium bicarbonate and bismuth may be given. But the measures most generally appropriate are hygienic and dietetic. In particular, the cold pack is highly effective. It must not be so prolonged as to bring on sweating, but should be terminated when the patient begins to feel warm and the pulse increases in frequency.

"THE BREADTH OF AN ATOM."

Speaking of a new "school" of geometry projected by a person who seeks to substitute for the accepted ratio of the diameter of a circle to the circumference one that he maintains is the right one, the Evening Post remarks that by extending the usual fraction to 707 decimal places one may so closely approximate the true ratio that "in creating a universe on it the largest possible circle would have an error of less than the breadth of an atom."

CATALEPTOID LETHARGY WITH SIMULATION OF CHYLURIA.

The devices to which hysterical patients sometimes resort in the attempt to simulate some grave disease are apt to be grotesque. For example, Rothmann and Nathanson (Archiv für Psychiatrie, xxxi, 1; Fortschritte der Medicin, September 20th) relate a case in which the patient injected milk into the bladder to counterfeit chyluria. There were lethargic and cataleptic paroxysms sometimes lasting as long as twelve days, with a rise of temperature to almost 108° F., acute diminution of the area of hepatic dullness, decrease of urea, and ammoniuria. Surely this patient need not have simulated an additional malady.

REMOVAL OF THE THYMUS GLAND.

At a recent meeting of the Magdeburg Medical Society (Münchener Medicinische Wochenschrift, 1899, No. 28; Wiener klinische Wochenschrift, September 21st) Dr. Purrucker reported the entire removal of the thymus in the case of a boy two years and three months old. The operation was resorted to on account of constantly increasing dyspnea. We are informed that no technical difficulties were encountered in the excision, but we are not told what effect it had on the dyspnea.

BLINDNESS IN FINLAND.

The different degrees to which blindness prevails among various populations is always a matter worthy of study. J. Widmark has investigated the subject as regards Denmark, Sweden, Norway, and Finland (Nordisk medicinsk Arkir, August). He finds that for every 10,000 inhabitants there are 5.3 blind persons in Denmark, 8.3 in Sweden, 12.8 in Norway, and 15.5 in Finland. The preponderance in Finland, which is not observed among children under ten years of age, is attributed to the great prevalence of trachoma. Curiously enough, the "endemic" affects only the natives.

ENTEROPEXY FOR VOLVULUS OF THE SIGMOID FLEXURE.

At a recent meeting of the Prague Society of Bohemian Physicians (Wiener klinische Rundschau, September 17th) Dr. Wenzel Kopfstein related a curious case of volvulus of the sigmoid flexure. In three attacks, all accompanied with symptoms of obstruction, reduction was effected without a cutting operation, but in the fourth laparotomy was performed and the intestine, which was found bent at a right angle, was restored to its normal shape and stitched to the peritoneum of the anterior abdominal wall to guard against further relapses.

TYPHOID FEVER WITHOUT INTESTINAL LESIONS.

There are reasons for supposing that typhoid fever unaccompanied by lesions of the intestinal glands is commoner than has been generally realized. In the October number of the Canadian Journal of Medicine and Surgery Dr. A. McPhedran, professor of medicine in the University of Toronto, gives a detailed account of a case, and tabulates nineteen others which Dr. A. W. Tanner has been able to find recorded in various journals during the last few years. Dr. McPhedran looks upon such cases as showing "the irrational basis on which the purgative and miscellaneous eliminative treatment rests."

THE PLAGUE IN SOUTH AMERICA.

The newspaper statement that on October 19th the plague was reported to the surgeon-general of the Marine-Hospital Service as present in Santos need not be regarded as serious. Dr. Havelburg is said to have reported that there had been six cases, with two deaths, and to have added that isolation was possible. It will be seen by reference to the Marine-Hospital Service Health Reports published in this issue that the report covering the week ending October 20th makes no mention of the plague in Santos.

A NEW CLEVELAND JOURNAL.

The Bulletin of the Cleveland General Hospital completes its first year of publication with the issue of the October number. It is a quarterly edited, under the auspices of the hospital staff, by Dr. Charles J. Aldrich. It is a worthy addition to our periodical literature, and we wish it a full measure of success.

ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the week ending October 21, 1899:

<table>

The Chicago Society of Internal Medicine.—At the next regular meeting, on Tuesday evening, the 31st inst., the following papers will be presented for discussion: The Effects of Venin on the Myocardium, by Dr. S. A. Matthews; and Sphagnum Nutans, by J. A. Abt. The presidential address will be delivered by Dr. John A. Robison.

The Buffalo Academy of Medicine.—At the last regular meeting of the Section in Obstetrics, on Tuesday evening, the 24th inst., Dr. Herman E. Hayd read a paper entitled Pus in the Pelvic Cavity.

Change of Address.—Dr. E. Wood Ruggles, from No. 71 East Avenue, to No. 294 Alexander Street, Rochester, New York.

Army Intelligence.—Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from October 14 to October 21, 1899:

| Bradley, Alfred E., Major and Surgeon, United States Volunteers, assigned to duty temporarily as chief surgeon of the department, and as attending surgeon in St. Paul. |

CLARK, John R., Acting Assistant Surgeon, will report to the commanding general, Department of California, for duty with troops going to the Philippine Islands, upon the arrival at San Francisco of the U.S.S. Alabama, James B., Acting Assistant Surgeon, United States Navy.

HALLWOOD, James B., Acting Assistant Surgeon, will proceed from Fort Crook, Nebraska, to San Francisco, for duty at the General Hospital.

KIRKPATRICK, Thomas J., First Lieutenant and Assistant Surgeon, is granted leave of absence for eight days.

LAWRISON, George B., Acting Assistant Surgeon, United States Navy, is assigned to duty in the Province of Havana and Pinar del Rio, and will proceed to Quemados, Cuba.

SMITH, Bat, Acting Assistant Surgeon. The order relieving him from duty at the General Hospital, Santiago, and ordering him to the United States, is revoked.

Naval Intelligence.—Official List of Changes in the Medical Corps of the United States Navy for the Week ending October 21, 1899:

BEEBE, D. G., Assistant Surgeon. Detached from the Bennington and ordered to the Ranger.

CARPENTER, D. H., Assistant Surgeon. Detached from the Olympia and ordered home to await orders.

HAAS, H. H., Assistant Surgeon. Detached from treatment at the Naval Hospital, Yokohama, Japan, and ordered to the Baltimore.

HIGH, W. E., Assistant Surgeon. Detached from the Celtic and ordered to the Manila.

NORTON, O. O., Surgeon. Detached from the Rodger and ordered to temporary duty on the Ranger. On arrival at the Asiatic Station ordered to the Monadnock.

PERCY, H. T., Surgeon. Detached from the Olympia and ordered home to await orders.

PLUMMER, R. W., Assistant Surgeon. Detached from the hospital at the New York Navy Yard and ordered to temporary duty on the New Orleans for passage to the Asiatic Station.

ROSENLEUTH, J. C., Passed Assistant Surgeon. Detached from treatment at the Naval Hospital, Chelsea, Massachusetts, and granted sick leave for one month.

Snyder, J. J., Assistant Surgeon. Ordered to the New Orleans.

STOGHTON, J., Passed Assistant Surgeon. Detached from the Monadnock and ordered to the Bennington.

THOMPSON, E., Assistant Surgeon. Detached from the Manila and ordered to the Celtic.

YOUNG, L. L., Passed Assistant Surgeon. Ordered to be examined at the Mare Island Navy Yard, thence home to await orders.

Marine-Hospital Service.—Official List of Changes of Stations and Duties of Commissioned Officers of the United States Marine-Hospital Service for the Seven Days ending October 29, 1899:

WADSWORTH, Eugene, Surgeon. To proceed to Berlin, Germany, for special temporary duty.

WERTEBReker, C. P., Passed Assistant Surgeon. To proceed to Montezuma, Georgia, for special temporary duty.
DECKER, C. E., Assistant Surgeon. Relieved from waiting orders and placed on duty to date from October 7, 1899.

Appointment.

BOYD, FRANK, of Kentucky, to be Acting Assistant Surgeon, United States Marine-Hospital Service, for duty at Paducah, Kentucky.

Society Meetings for the Coming Week:

TUESDAY, October 31st: American Public Health Association (first day—Minneapolis); Rome, New York; Medical Society: Medical Societies of the Counties of Queens (semiannual—Garden City) and Rockland (semiannual), New York; Boston Society of Medical Sciences (private).

WEDNESDAY, November 1st: American Public Health Association (second day); New York Academy of Medicine (Section in Public Health); Society of Alumni of Bellevue Hospital: Medical Microscopical Society of Brooklyn; Medical Society of the County of Richmond (New Brighton), New York; Penobscot, Maine. County Medical Society (Bangor); Bridgeport, Connecticut. Medical Association.

THURSDAY, November 2d: American Public Health Association (third day); New York Academy of Medicine; Brooklyn Surgical Society; Society of Physicians of the Village of Canandaigua, New York; Medical Society of the County of Orleans (annual—Albion), New York; Obstetrical Society of Philadelphia; United States Naval Medical Society (Washington); Medical Society of City Hospital Alumni, St. Louis; Atlanta Society of Medicine.

FRIDAY, November 3d: American Public Health Association (fourth day): Practitioners’ Society of New York (private); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society.

SATURDAY, November 4th: Manhattan Medical and Surgical Society, New York (private); Miller’s River, Massachusetts. Medical Society.

Letters to the Editor.

A RESTRICTED DIET AS A CAUSE OF BERI-BERI.

327 Franklin Street, Buffalo, October 1, 1899.

To the Editor of the New York Medical Journal:

Sir: I find in your number of September 23d, page 463, second column above: “As to the theory propounded by the Dutch East Indian doctors, that white rice (so largely eaten by all East Asians), being infected with a micro-organism of beri-beri, is the means of propagation of the disease, he says that rice is always eaten well cooked (as the bread of the East), and that therefore a micro-organism, if it existed in white rice, would be destroyed, and consequently could not have anything to do with beri-beri.”

Now, so far as I know, the Dutch East Indian doctors might have thought about and looked after a specific bacterium, but they have never been able to find it, and so have tried to find other causes.

On the contrary, there is a large part of the profession in the Netherlands (from where nearly all the doctors for the East Indies come) who believe that the chief cause is to be looked for in an insufficiency of rice as food. E. van Dieren, M. D., of Amsterdam, has contended now for thirteen years, in the most logical and scientific way, that beri-beri is caused by the use of poisoned rice. His conclusions are the following:

Beri-beri, ergotismus (acrodynia), pellagra, and lathyrisme are caused respectively by rice, grain, maize, and vetch poisons.

These poisons have a similar effect on the human being (possess perhaps a similar composition).

It is more than probable that also from other sorts of meal poisons may develop which are identical with the one referred to or similar to it.

Monotonous subsistence on one or another sort of meal is in itself dangerous, the more dangerous as the meal is poorer in albuminous and fatty substances.

A diet chiefly consisting of rice is in itself very noxious, because the rice meal contains only a small quantity of those components. Such a diet becomes dangerous if the meal is the bearer of a poison, the more dangerous as less albuminous and fatty substances are given with it.

It would take too much time to follow Dr. van Dieren in his way of reasoning, though it would not be time lost, but the conditions in Japan and the Straits-
Settlements have given him full justice. For Japan he refers to Dr. Takaki, who mentions that because the Japanese authorities considered rice to be too great a luxury for the prisoners, they changed it for barley. This change in diet was followed by a considerable diminution of the sufferers from beri-beri, which prosperous condition continued, so that the beri-beri ceased to exist after two or three years, and even without other precautions having been taken. Also Takaki mentions that the beri-beri ceased to exist in the navy, the reason of which was to be found in the change of diet, which happened in 1884.

I could cite many more points from the works of Dr. van Dieren, but must leave the further discussion to more competent men than myself.

A VARIANT OF THE STORY OF THE THREE LANTERNS.

4528 Chouteau Avenue, St. Louis, October 19, 1899.

To the Editor of the New York Medical Journal:

Sir: I read with pleasure the story of the three lanterns in your issue of September 9th, also the new version contributed by Dr. Ashmead, in your issue of October 17th. I know an old version, which I think is better than either, which runs as follows:

A man possessed a magic charm which enabled him to see the souls of murdered persons in the front yards of their murderers. This man, while on a journey, was taken sick, and asked the hotel clerk, or some other valuable person, to direct him to a good physician. He received the names and addresses of several, but when he went to call on them saw so many souls in their front yards that he dared not trust them. He wandered on, trying to find a physician with no souls in his front yard, but was unsuccessful. When about to give up the quest, he discovered a doctor's house in front of which was only one ghost, and that an old woman who looked as if she might have died of old age. He decided to try this doctor, and his ring at the bell was answered by the doctor himself, who invited him in. After the prescription was written, the patient observed:

"Doctor, I understand you are very successful in your practice."

The doctor seemed surprised and, after a moment's hesitation, responded: "Would you mind telling me who recommended you to me?"

The man, not caring to give away the secret of the charm, said: "Oh, one of your former patients."

But the doctor, shaking his head, replied: "No, that can hardly be. I have never had but one patient, and I'm quite sure she didn't recommend me."

THE LAW IN ITS RELATIONS TO PHYSICIANS.

By ARTHUR N. TAYLOR, LL. B.

CRIMINAL LIABILITY.

(Continued from page 604.)

Proving Unlawful Performance of Abortion: Illustrations.—In cases where the mother dies from the operation it may happen that the fact that an abortion has been performed can not be shown by any living witness. In such cases the only manner of proving the corpus delicti, or body of the wrong, is by having a competent medical man perform a post-mortem and then testify before the jury as to the condition which he found present. In addition to the evidence which such a physician gives as to the condition of the deceased, it is competent for him to also express his opinion or belief as to whether she was pregnant, and, if so, whether or not an abortion had been performed upon her, and give his reasons for such belief. And so, where the defendant alleges that the deceased operated upon herself, and that he was called in after such operation and superintended her delivery of a dead fetus and afterbirth, and acted only as an honest medical practitioner should act when called to attend a woman suffering from such injuries, it is competent for a skillful physician and surgeon who has examined the uterus of the deceased to testify whether or not in his opinion the injuries he found thereon were self-inflicted.

The case of State vs. Howard is a revolting one, in which the fact that an abortion had been performed seems to have first become known through a post-mortem examination. Here the evidence showed that two girls, the deceased and her sister, left their homes for the purpose of visiting relatives in a neighboring town. Soon afterward they left the house where they were visiting for the ostensible purpose of taking an excursion into an adjoining State, but instead they went to the house of the defendant, a practising physician; about two weeks after arriving there the deceased expired. Her body was placed in a coffin and she was sent to her home and buried, but a few days afterward was disinterred and a post-mortem examination made. The examination extended through the body and internal organs, but no examination was made of the brain. The external opening of the vagina was greatly extended, so that the hand, without much difficulty, might be passed in; the uterus was enlarged in size, its walls were thickened, and its blood-vessels were increased in size and number, as is usual in case of pregnancy, and internally there were marks of the attachment of a placenta, that had been removed, leaving open sinuses; the breasts were distended, and contained milk, and there was a dark area on about each nipple; the month of the womb was then about half an inch in diameter; the neck of the womb was greatly inflamed, and the lining membrane had been taken off; there were sloughs and holes in the substance of the neck; the body of the womb was healthy, and all the internal organs of the body were in a natural and healthy condition. The physician who performed the post-mortem examination testified, upon the trial of the case, that in his opinion the direct cause of the death was the inflammation of the neck of the womb, and perhaps hemorrhage; that that was a sufficient cause of death; that there had been a fetus in the womb from four to seven months old that had been expelled before the examination. He also testified that he had removed the uterus and preserved it in alcohol, and upon request of the counsel for the State he produced it. It was exhibited to the jury and the various parts and marks were pointed out and described.
The State then produced a witness who testified to the finding of a fetus upon the premises of the defendant. The admissibility of this evidence was contested by the defendant, but it was admitted as tending strongly to show the corpus delicti.

Deceased's sister then testified that when she and deceased left home it was understood between them that an abortion was to be performed upon deceased; that just before going to the defendant, who lived in a village some miles distant from the one in which they were visiting, deceased met the father of her child, who, it seems, had arranged with defendant to take the case; that arriving at the house of the defendant they told him deceased's condition, that she was six months advanced, and that they desired him to procure an abortion; that he did not consent at first, but, after corresponding with the child's father, agreed to go through with the operation for one hundred dollars; that defendant first gave deceased medicine in the form of bitters, about a goldleafful at a dose, which operated as an ectic and cathartic. That about a week after their arrival defendant performed an operation upon deceased with instruments, she lying on the bed in their room, the witness being present; that he used two or three instruments; that he used the instruments internally upon the private parts of deceased, who complained of pain and its hurting while the operation was going on; that discharges of water came from her, which continued to flow for two or three hours more; that on the next day defendant made another operation in a similar manner and attended by pain, which was indicated by complaints and gripping of the hands; that the result of this operation was flowing, and that the witness saw considerable blood; that near night of the same day defendant performed a third operation, making the same use of instruments as in the former operation, and in connection therewith introduced his hand; that the result was a child about two thirds grown; that defendant took the child from the room and witness saw it no more. From the further evidence it seems that deceased lived a week after the first operation; that she was delirious several days before death and became violent.

The theory upon which the defense was conducted was that deceased, before going to defendant's house, had taken strong medicines, which were accounteable for the miscarriage and her subsequent death, and that the professional services rendered to her by defendant were only such as her condition required from a physician in the honest and conscientious practice of his profession. To show this, an inmate of the defendant's household was introduced as a witness, who gave in evidence as a dying declaration the following statement of the deceased. The witness said that on Thursday, the day before the patient's death, about noon she had a conversation with her while her sister was at dinner; that deceased told witness she thought she could not live and did not expect to; that she had been taking powerful, poisonous medicines before she came to defendant's, and she thought she had destroyed her life, and that that was what had caused her mouth to be sore; that she hoped they would not blame the doctor; and that she thought he had done everything he could to restore her health, and that she had been out of health a long while. The witness testified that she did not see any indication that deceased was not perfectly sane, and that witness had never discovered any insanity about her, and had no suspicion of it; that she seemed sane through that day, but that on the next morning she seemed to have lost her reason.

The State introduced witnesses who testified that about four o'clock Thursday morning, the day upon which the above conversation was said to have taken place, the deceased became violent and kicked off the footboard, and that she was not in a condition to be able to converse during the day.

Other evidence of a cumulative or corroborative character was given by both sides. The jury found the defendant guilty of the procurement of an abortion.

The case was appealed to the supreme court and there affirmed, after which the defendant was sentenced to the State prison.

In the case of State vs. Glass is an illustration of the application of the rule admitting evidence of statements which form part of the res gestae. Here the deceased applied to two physicians, informing them of her condition and asking them to perform an abortion upon her; they both refusing, she then went to the defendant. The State, in order to prove the condition of the deceased, called two physicians as witnesses and had them testify regarding the statements made to them by deceased. The introduction of this evidence was objected to by the defendant, but it was admitted as part of the res gestae. The supreme court, in reviewing the case, held that the trial court ruled correctly in admitting this evidence. Here the statements admitted related so intimately to the condition which was the principal inducement to the crime for which the defendant was being tried, and were made under circumstances where every possible inducement to suppress, conceal, or distort the truth was overcame, that they could not well be considered otherwise than as admissible upon the grounds named.

Nor, it has been held, can the evidence of a physician who is called upon professionally to perform an unlawful abortion be objected to upon the ground that the knowledge thereby gained by him is privileged, it being a general rule that communications which ordiarily are privileged, are not privileged if made for an unlawful purpose, having for their object the commission of a crime.

This rule is illustrated in the case of State vs. Smith. In this case the evidence showed that the prosecuting witness, an unmarried woman of twenty-three, who was advanced between five and six months in pregnancy, came to the house of the defendant, a practising physician, on the 25th of September, where she remained for some time, and that on the morning of October 5th she had a miscarriage.

The prosecuting witness testified that previous to the time of her going to defendant's house she was in sound physical health and that no attempt had been made to produce a miscarriage. She testified that on the morning of her arrival defendant began treating her for the purpose of producing a miscarriage, and that certain medicines and instruments were used upon her, and that a miscarriage followed their use.

The testimony of the defendant was that the complaining witness came to her for treatment and that she was in a deranged condition: "that the uterus was sore, swollen, and very much inflamed, and it looked like it had been punctured in the mouth of it, and all

* State vs. Glass, 5 Or., 73.
† See succeeding article.
‡ State vs. Smith, 99 La., 26, 68 N. W., 428.
around the sides”; and that it was “tipped,” the parts swollen, and a discharge coming therefrom. Defendant admitted that she used the kind of instruments named by prosecuting witness, but testified that they were used in a different way and for a different purpose from that stated. She described the treatment given, and said it was proper treatment under the conditions to prevent a miscarriage. Several experienced physicians confirmed her in this statement as to the propriety of the treatment, under conditions such as she stated existed, while one or two others condemned the treatment. Defendant further testified that on the fourth day of October she found the head of the fetus in the vagina, and that it had commenced to leave the uterus, believing that a miscarriage could not be prevented, and that the obstruction must be removed, and having no instruments, defendant sent for another physician who, upon arriving, refused to have anything to do with the case, but, according to defendant’s testimony, advised that Nature be allowed to take her course. Whether anything further was done to prevent or produce the miscarriage the evidence does not show.

The physician who was called to remove the fetus was produced as a witness by the State at the trial and asked to state what he saw and did in the presence of the defendant. The defendant objected to the witness answering the question on the ground “that the things he saw, and the conversation he had with this defendant upon the occasion of the visit mentioned by him, were confidential, and that the knowledge he obtained upon that occasion was obtained in his capacity as a physician.” The trial court admitted the testimony of the witness. The defendant’s counsel excepted to the ruling and the question was reviewed by the supreme court, who held, in accordance with the rule above laid down relative to privileged communications, that as the facts and the testimony of this witness showed “that the communication of defendant to him was for an unlawful purpose and had for its object the commission of a crime,” it therefore was not privileged.

The witness testified as follows: “I went into the room and took off my overcoat, and laid down my instruments. (Defendant) told me that she had a friend from the southern part of the State; that she came there to be treated; that she was in the family way, and was to be married to a man in Pennsylvania, and must get out of this fix before she was to be married. She wanted that I should go into the room and examine the patient, and I refused to go. She told me that the girl was sick. I told her that I would have nothing to do with the case. I went into the other room and put on my coat.”

There was considerable other evidence given on behalf of both the defendant and of the State, yet the foregoing seems to have been the principal evidence upon which the case was decided. The jury found the defendant guilty of procuring a miscarriage and she was sentenced to imprisonment in the penitentiary.

The question of what length of time will be considered sufficient to afford an opportunity to operate is answered to a certain extent in the cases of Commonwealth vs. Drake,* and People vs. McGonegal.† In the former case the evidence showed that the woman upon whom the abortion was performed and the defendant were together fifteen minutes; this was thought to be sufficient time to afford opportunity for the operation. Here the woman upon whom the abortion was performed, and who for convenience will be designated as S., and a friend came from a distant town to the city where defendant lived for the purpose of having the abortion performed. The friend testified that they went to defendant’s house, where S. told defendant of her condition; defendant and S. were then alone together for some fifteen minutes. In answer to a question by defendant’s counsel, the witness testified that S. told her that defendant had operated on her with something which she concealed with her handkerchief. Witness further testified that S. suffered great pain that night; that two days later, having been ordered from their lodging house by the keeper, they went to the house of defendant and remained there three days.

The defendant denied that either S. or her friend had ever been in the house.

A hack driver testified that he drove the two girls from their lodging house to the corner near where defendant lived, but that he did not know where they went.

There was nothing further to connect the defendant with the procuring of the miscarriage except that the friend, who had always lived in a distant town, described accurately the interior arrangement of the house of the defendant. The jury found the defendant guilty of the crime of procuring an abortion.

In the case of People vs. McGonegal the deceased and defendant were alone together in defendant’s office for a length of time not exceeding five minutes in duration. The State showed by expert testimony that this length of time might have been sufficient for the purpose; this, in addition to the fact that the evidence showed that defendant had met deceased some days previously, and that there had then been an opportunity to arrange for the operation, was held sufficient to justify the jury in finding that there was an opportunity to commit the crime. In this case the defendant was convicted upon circumstantial evidence. The evidence showed that a friend and intimate companion of the deceased, who knew of her pregnancy and her desire to obtain relief by prohibited means, accompanied her to the office of defendant on July 26; that the friend remained in the reception room while the defendant and deceased were in the private office together, but that they remained there not longer than five minutes. On the 4th of July deceased was taken sick and defendant went to see her at her lodging house, and, it seems, was informed by the landlady that if there was anything wrong with the patient she must be removed. That night at about eleven o’clock defendant took the patient to another house where she remained until her death, which occurred eight days later. Upon the death of the patient the defendant removed the body himself at about twelve o’clock at night to the undertaker’s, and gave a certificate of death, ascribing it to inflammatory rheumatism of the heart. It also appeared that several days subsequent to the patient’s death defendant went to deceased’s friend for the purpose of getting her to write or sign a letter purporting to come from the deceased which should say that she was doing nicely with an old friend of hers, working every day and Sunday, and would be home in a month or two; not to worry. About ten days after patient’s death the body was exhumed and an autopsy held which showed that the death was caused by peritonitis, resulting from an abortion which had been performed upon deceased.

* Com. vs. Drake, 124 Mass. 21.
† People vs. McGonegal, 17 N. Y. Supp. 147, 136 N. Y. 62.
The defendant's evidence was that when deceased called upon him on July 2d she informed him of her condition, from which he apparently inferred that she desired him to operate upon her. She said that she had been making efforts in that direction herself, and that she was then complaining of the pains that are usually regarded as a premonition of a miscarriage; that he would not do anything to aid her in the way of procuring a miscarriage, but told her to go home and take care of herself, and that he would treat her, if she wanted him, to the best of his ability. Defendant stated when he called upon deceased on 4th of July he did not recognize her as having called upon him before, and that he did not make any particular examination of her, apparently because of the demand of the landlady for her immediate removal. The defendant's evidence does not show when he recognized deceased as the person who visited him at his office on July 2d. It seems that defendant testified that during all the time he was treating deceased for rheumatism, he made no examination whatever to ascertain whether the efforts made by deceased to produce an abortion, as previously testified to by him, had had any results or not.

The jury found the defendant guilty of manslaughter. An appeal was taken to the general term of the supreme court where the judgment of conviction was affirmed, and from there the case was taken to the court of appeals, with like result. The court of appeals, after reviewing the evidence, said: "If innocent, it was his misfortune to voluntarily envelop himself in a network of circumstances which, to the minds of intelligent men required to reach results by rational processes, would admit of no other conclusion than that of guilt."

(To be continued.)

Pith of Current Literature.

Observations on the Anatomy and Physiology of the Ear.—Dr. W. F. Cole (Laryngoscope, August) says that the accepted theory of hearing is that sound vibrations are transmitted from the membrana tympani through the ossicles to the vestibule and thence to the cochlea, though it is accepted that some sound passes through the air of the tympanum and the fenestra rotunda. His own observations and experiments have led him to believe that the reverse is true. He has also been enabled to clear up the mystery of the so-called artificial membrana tympani. He has reason to assert that sound ordinarily passes not through the ossicles and fenestra ovalis, but through the air of the tympanum and fenestra rotunda. His theory is not new, for according to Politzer it was advocated by the older physiologists, particularly Pascal, and at a later date by Sapolini and Pecchi; but he does not know upon what grounds they based their theories. His theories are based entirely upon his own observations and experiments, and upon deductions therefrom. At Atlanta, in March, 1898, he related his first experiments. A young lady, attending college, consulted him. She had suffered with otorrhoea in both ears from childhood, and was subject to occasional attacks of mastoiditis. She had neither membrana tympani nor ossicles in either ear. The discharge in both ears was from the attic, in the left it was slight, while in the right it was profuse. The hearing, as to distance, was from the right about six tenths, the left one tenth—that is, for the right she heard eighteen feet, where she should have heard thirty feet. He did mastoid operations on both sides. After the operations, the hearing for the left was unchanged, but for the right she heard at five feet what she should have heard at forty. She was compelled to leave school for lack of hearing. He tried various artificial membrane tympani with no success, except a paper tube, which gave fair satisfaction when it was placed right by accident. Her hearing departed with the cessation of the otorrhoea. He continued to see her occasionally for the purpose of treating the ear and experimenting with the various artificial membrane tympani. On these occasions he irrigated the ear with a syringe. While the water remained in the attic her hearing was acute. But, to use her own language, "It departed with a gurgle." Such phenomena had been noted by most oologists and the accepted explanation had been that the water acted as a conductor to the fenestra ovalis in lieu of the ossicles. It occurred to him on one occasion that perhaps the improvement might be due to concentration of the sound waves upon the fenestra. It should be borne in mind that in the normal ear the tympanum was practically a closed cavity, being cut off from the attic and antrum by the ossicles and ligaments; so that when they and the membrana tympani were destroyed the external auditory canal terminated in an enlarged cavity composed of the tympanum, attic, and antrum. This might be illustrated with a speaking tube in which the tube terminated, not in the small ear tip, but in a very much enlarged opening, the sound waves being dispersed instead of concentrated. He found that cotton wool placed in the attic and anterior part of the tympanum acted in the same way as the water had done. He found that the effect was the same whether the fenestra ovalis was or was not closed so long as the attic was closed, and that the hearing was lessened when the posterior part of the tympanum was covered with cotton saturated with water or vaseline.

These experiments explained to him the occasional improvement of hearing in such cases by the so-called artificial membrana tympani, as being due to the accidental cutting off of the attic and antrum, and the concentrating of the sound impulses upon the fenestra rotunda. His conclusions were verified in numerous other cases.

The application of the cotton wool being unpractical, he began to devise some other means of concentrating the sound upon the fenestra rotunda. He found good results from the use of a section of thin rubber tube, such as Politzer used for the poor, but this tube was uncertain because the wall of the tube did not cover the fenestra or else the wall of the tube covered it by slipping over the promontory. He overcame this fairly well by cutting a notch from one side of the inner end of the tube, which would allow the sound to pass to the fenestra, the notch being directed to it. These tubes were imperfect, however, in consequence of the fact that they did not fill the meatus properly nor direct the impulses upon the fenestra. He then devised some cone-shaped tubes, which had been quite satisfactory in a number of his own cases as well as others.

Theories long promulgated, he said, attained almost the force of scientific facts. The theory that sound passed to the internal ear through the ossicles was a
familiar illustration. Elaborate experiments had been made to illustrate the fact, and when Edison perfected the phonograph many aurists accepted this as conclusive proof, and to a superficial observer it did appear pretty conclusive; but the author’s investigations led him to assert that Mr. Edison’s phonograph proved his theory that sound passed to the internal ear not by way of the ossicles, but through the air of the tympanum and the membrana tympani secondaria. When we examined the structure of the drumhead we found it a thin membrane whose strength was due to muscular fibres which radiated from the handle of the malleus to the periphery of the tympanum, and these fibres were as various in length as the strings of a harp. Furthermore, the membrane was not uniform in tension nor was it of uniform thickness, so that the different segments of the membrane would have different fundamental pitch and would vibrate to different tones as did the strings of an instrument. In no other way could we account for the capacity of the human ear to hear so great a multiplicity of sounds at the same instant. It was well known that the director of an orchestra or a chorus of voices could easily distinguish the tone of any instrument or any voice from all the others; but the phonograph could not copy an orchestra nor a chorus as heard by the human ear because it had not the capacity, for the metallic diaphragm vibrated not in segments but as a whole. Many tones were neutralized in their impulses upon the metallic disc, due to the condensation of one sound wave being synchronous with the rarefaction of another wave.

The author asserted that the phonograph could not repeat orchestral nor choral music as heard by the human ear. The loudest sounds would make their impression upon the wax, while the interference of others would result in a squeak. He believed that sounds of great volume and intensity did pass to the internal ear through the ossicles, the membrana tympani vibrating as a whole. What then were the functions of the ossicles and the tympanic cavity? The ossicles were nothing more than a system of levers to regulate the tension of the membrana tympani, much the same as the bridge and the sounding post in a musical instrument regulated the tension of the strings. The tympanum served much the same purpose as the body of the violin to reinforce or magnify sounds. The principle of the reinforcement of sound by confined bodies of air was well understood in acoustics, being the foundation principle in all musical instruments. As previously stated, the mechanism of the human ear was peculiar to mammals. When the outer drumhead and the ossicles were destroyed a person heard in much the same manner as a serpent whose membrana tympani was united to its skin. If the tympanum and labyrinth were eliminated one would hear in much the same way as the snail, and, strange to say, Sexton, Gruber, Bezold, Goldstein, and others had reported cases of some hearing where the whole of the labyrinth had been exfoliated. In the use of the author’s tubes he had only applied the well-known principles of acoustics, concentrating the sound impulses upon the inner drumhead or membrana tympani secondaria.

The Excretion of Uric Acid.—Dr. William Bain (Edinburgh Medical Journal, October) says that the interest in uric acid arises chiefly from the influence it is supposed to exercise in the causation of gout. The amount excreted in health varies considerably in different individuals, and this variation by no means necessarily depends upon the food taken. If a healthy subject is placed upon a fixed diet, other conditions remaining as much as possible the same, the excretion still shows daily variations. If the uric acid was derived entirely from the ingesta, the only possible explanation of this variation would be that, although the food taken was the same in kind and quantity, the amount assimilated varied, but as this is more or less of an assumption there is another supposed origin of this acid which will be considered. It is well known that nuclein and nucleo-proteid greatly increase the excretion, and Horbaczewski’s view that uric acid is derived from the nuclein of the white cells imparts additional interest to the question of the mode of production of the acid. Some support has been given to this theory by experiments recently recorded, in which it has been shown that the variations in the number of leucocytes bear an inverse ratio to the variations in the excretion of uric acid, but it is difficult to understand why this nuclear origin should be restricted to the leucocytes. If the uric acid is partly derived from the metabolism of leucocytes, in all probability the other tissue cells (all of which contain nuclein) share in its production. If at the same time the phosphoric acid was shown to follow closely the uric-acid excretion, the nuclear origin would be strengthened.

Two Special Forms of Catarrhal Jaundice.—Dr. Launder Bruntton (Edinburgh Medical Journal, October), in a clinical lecture delivered at St. Bartholomew’s Hospital, says that “there are two special classes of catarrhal jaundice—namely, 1, that which is due to thickening of the duodenum itself; 2, that which is due to the presence of mucus in the duodenum. In the case where the catarrh is present in the duodenum, it usually begins in the stomach, spreads to the duodenum, and then involves the bile duct; and the symptoms you get in such cases are, that the patient for two or three days before the jaundice is a little sick, a little out of sorts, has not very much appetite, and feels a little qualmish. In the cases where it seems to begin in the bile duct itself, there are no symptoms whatever, and the patient goes out one fine morning, and he meets a friend, who says, ‘You are very yellow to-day.’ He goes back and looks in the glass, and finds that he is yellow, but if it were not for the yellowness he would be perfectly well; and he comes simply to get the yellowness removed. As a general rule, you give him a blue pill, or a pill containing either mercury or calomel. One generally gives a mercurial pill with some rhubarb, podophyllin, coloehyolic, or some purgative, and a saline aperient to follow. This I suppose sometimes does good; at any rate, it is the general treatment, and you never prescribe some nitrohydrochloric acid, bismuth, or salicylate of sodium. All these drugs are used in cases of catarrhal jaundice; sometimes they do good and sometimes they do not.”

Prickly Heat.—Dr. St. George Gray (Journal of Tropical Medicine, August), replying to Mr. Frederick Pearse’s communication in the Journal for June (cited in the New York Medical Journal for July 29th), says that where the perspiration evaporates rapidly or can be drained away by absorbent underwear there is little or no prickly heat, and clinical experience bears this out. As the sufferers generally look upon it as an inevitable accompaniment of their residence in the tropics, and as it is also looked upon by many as a
"healthy sign," it is rarely brought to the notice of their medical attendant. Most of his investigations, therefore, have been made on his own person. When he first came to the tropics he wore the thinnest of cotton underclothing and was hardly ever free from prickly heat all over his body. When wet with perspiration this was extremely uncomfortable, and he soon realized that cotton was not the ideal material for underclothing in the tropics. He then began to wear wool next to his skin, with the result that prickly heat has never troubled him since, except on those parts of the body not covered by wool or exposed to the air—viz., the forearms from the lower edge of the woolen sleeve of the undershirt to the lower edge of the linen cuff at the wrist. Several of his patients who wear woolen underclothing have prickly heat only on their forearms. The wool absorbs the perspiration as fast as it is secreted, and carries it away from the skin to the outer garments, so that the epidermis never becomes sodden, and consequently the orifices of the sweat ducts remain patent.

The thinnest material will do, provided it is wool. Woolen underclothing is also the best protective against the sudden changes of temperature which are so common in the tropics, and is certainly more comfortable, even in the hottest weather, than wet cotton or linen next to the skin.

By all means let the subject of prickly heat bathe in plain, cool water, without soap. In such a case there is nothing more grateful than a good soak in a tub of rain water or in a mountain torrent, until thoroughly cooled—not chilled—then a brisk rubbing with a rough towel, and afterward gentle exercise to prevent a chill, but not sufficient to cause undue perspiration.

Mr. Pearse says: "Lanolin, when freely used (and it must be very freely used), and when combined with a pleasant oil, is the most successful application." Dr. Gray considers that his very treatment, which is undoubtedly the correct one, shows that he perceives that there is a deficiency and not an excess of sebaceous matter in the skin, which would be the case were prickly heat a seborrhoea.

Theoretically and practically, no doubt the free use of lanolin is the very best curative treatment for prickly heat (always excepting change to a cooler climate), but Dr. Gray does not think that many Europeans will submit to it for any considerable length of time.

The only certain and permanent cure for prickly heat is cold weather. On removal to a cooler climate the eruption disappears as if by magic, however intractable it may have been before, only to appear again with all its attendant discomfort when the sufferer returns to the tropics.

A Novel Urethrotomy for Stricture.—Dr. Mark Wardle (Edinburgh Medical Journal, October) records the following case whose interest lies in a novel method of procedure: The patient, a fairly healthy man, aged forty years, had suffered from stricture for many years, and when admitted to the Union Hospital was able to partially empty the bladder by great effort in a small dribbling stream. After prolonged and careful effort, the author was quite unable to get any size of catheter into the bladder. He therefore, on the 12th of June, placed him under an anaesthetic and passed a No. 4 elastic catheter past the first stricture, and, as he hoped, into the commencement of a second. Putting him into the lithotomy position, he endeavored to localize the point of the catheter, intending to cut down on it, and then to open up the stricture and pass the catheter on into the bladder. It was, however, quite impossible to feel the catheter point. He therefore steadied the urethra with the forefinger and cut down to the point where he guessed the stricture to commence. He was thus able to easily enter the urethra, and then passed a director into the bladder. The catheter could then be readily felt in a false passage. He then passed a No. 9 elastic through the wound into the bladder and, dividing the wall of the false passage, brought the point of the No. 4 out of the wound. After taking off the bone head of the No. 9, he inserted the No. 4 into the No. 9, and, using the smaller one thus as a guide, was able to push the No. 9 outward, along the urethra and through the meatus, with the easiest ease and quickness. The wound was carefully closed by a deep continuous suture and superficial interrupted ones. It healed without any untoward symptoms, and the catheter was allowed to remain until the seventh day. A No. 10 was then introduced without difficulty, and left for twenty-four hours. After that the patient emptied his bladder naturally in a full stream without difficulty. The No. 10 was passed once a day until he was discharged cured on the eighteenth day.

The author adds that in cases of multiple stricture this method seems to him to present a quick and fairly easy method of getting a good-sized catheter in situ, the smaller one, on being passed into the larger, forming a safe and certain guide upon which the larger can emerge.

Obstinate Hiccough after Operation.—Dr. Arthur Powell (British Medical Journal, September 30th) records the case of a Mussulman, aged thirty-five years, in whom lithotomy under chloroform was performed. A violent hiccough set in on the table and was continued for fifteen days. Every species of text-book treatment, including antispasmodics, narcotics, emetics, purgatives, counter irritation at epi gastroium and over the phrenics, was tried without avail. No cause was to be found for the hiccough, which disappeared as suddenly as it had begun. A dose of chloral hydrate had been taken a few minutes previously, but recovery is not attributed thereto.

Iodipin in the Treatment of Advanced Syphilis.—Klingmüller (Berliner klinische Wochenschrift, 1899, No. 25; Fortschrifte der Medizin, September 6th) recommends the subcutaneous use of iodipin (a ten-per-cent. organic compound of iodine with oil of sesame) in daily amounts of twenty cubic centimetres for five successive days. In this way he obtains results equal to those following the protracted use of potassium iodide, and without any unpleasant effects.

twenty-seven years; Texas; eight years' chronicity, right side of the body. Wright (Transactions of the Association of American Physicians, 1895, vol. xii, p. 471): Woman, aged twenty-six years; Italy and United States; six months' chronicity, left side of the body. Arwine and Lamb: Man, aged forty-five years; Texas; twelve years' chronicity, left side of the body.

It is probable, says the Journal, that, as suggested by Professor Adams of Montreal, a careful examination of previous cases would disclose additional specimens; it is probable, also, that many cases of this disease have been erroneously diagnosed as elephantiasis. Inasmuch as the two American cases in possession of the army medical museum came from Texas, it would seem likely that that section of country would be an inviting field for research. Since, also, in India at least, the disease is found almost exclusively among the peasantry who go barefoot on the soft plowed ground, tropical and semitropical America ought, theoretically, to furnish many more cases than the few which have been reported.

Tea Drinking as a Cause of Cold Feet.—Jonathan Hutchinson, F. R. S. (Archives of Surgery, vol. ii, p. 56; Medical Review, September), reports the case of a lady who could not take tea because it made her feet icy cold and wet with perspiration. She thought that the soles were chiefly affected, and that the hands were also made cold, but not so markedly as the feet. Mr. Hutchinson had long been familiar with the fact that tea made the feet of some persons cold, but did not know that cold perspiration attended it. He believed the coldness to be caused by contraction of the arteries, inasmuch as the feet shrank. Alcohol had usually an opposite effect.

Walcher's Obstetric Position.—Dr. Alfred Moore (Memphis Medical Monthly, October) recommends the placing of the woman on the table on her back, with buttocks projecting over the edge and her feet hanging down with thighs extended, in the position known as Walcher's, the opposite of that of lithotomy, or flexion of the thighs. In 1889 Walcher announced that by extending the thighs of a parturient woman the true conjugate was increased very nearly a centimetre. This is of importance, especially in difficult labors, where the gain of a fraction of an inch is of material value.

While the inlet to the pelvis is enlarged by this posture, the outlet is diminished, and as the head enters the cavity the thighs should be flexed, so as to allow the head more room at the outlet. The author then records the case of a primipara in whom a tedious labor, in which forceps failed to deliver, was promptly and easily terminated on the adoption of this position.

Itrul in Gonorrhoea.—Itrul (citrate of silver), says Treatment for September 28th, has been used as an injection for acute gonorrhoea by Wesler and others. Schill (Therapeutische Monatshefte, April) gives his views on the subject. As solutions of itrul readily decompose when brought into contact with organic material, the syringe must be washed out with hot water before use, and the silver solution must be put in a clean vessel. Wesler, who has treated fifty cases, used a concentrated solution, 1 in 4,000, diluted with warm water. There was no burning or smarting pain either during the injection or after it. He never met with cases of edema, hematuria, or retention following its use. It is important to commence treatment as early as possible, in order to prevent the gonococcii from implicating the deeper parts of the mucous membrane. Schill has employed this remedy during the last year, and has treated a hundred cases. He gives some practical rules to be observed in the treatment: 1. Itrul injections are to be commenced as soon as possible. 2. They should be carried out four or five times a day. 3. The syringe should contain from six to eight cubic centimetres. 4. The fluid must remain ten minutes in the urethra after the latter has been cleansed by half a syringeful of the injection. 5. The strength of the injection at the beginning should not exceed 1 in 10,000. The solution must always be used lukewarm.

Suprarenal Gland as a Hemostatic.—About a year ago, says Treatment for September 28th, Schäfer pointed out the hemostatic effect of suprarenal gland in epi-staxis, and during the last twelve months the extract has been used abroad to control the hemorrhage in operations on the nose and pharynx. Grünbaum (Journal of Physiology, May 11th) suggests that cases of haematemesis might be benefited by the administration of suprarenal extract if the active principle was not absorbed sufficiently rapidly to cause a rise in blood pressure, in which case the hemorrhage would not be controlled. The author made some investigations on his own blood pressure before and after doses of pulverized suprarenal tabloids, the hemostatic properties of which had been tested. An Oliver's sphynghy-dynamometer was used. The doses taken were ten, twenty, and thirty grains; the blood pressure was taken every ten minutes for three hours after the dose. No cardiac stimulant interfered with the results of the experiments. In no case was there an appreciable increase in blood pressure—that is, an increase beyond that of experimental error, which is four millimetres of mercury.

Other observations are cited with the same results, save in one instance, that of a pregnant woman. The negative results as regards the alteration of blood pressure in normal individuals are said to make it probable that suprarenal extract is an ideal hemostatic in hemorrhage from the walls of the alimentary canal or bladder.

Action of X Rays on the Skin.—Lambin (Monatshefte für praktische Dermatologie, No. 10, 1899; British Medical Journal, September 30th) has investigated the action of X rays on both healthy and diseased skin, and comes to the following conclusions: 1. The action is beneficial in cases of lupus, chronic eczema, destruction of hairs growing on moles, and occasionally in cases of acne, lupus erythematosus, favus, psoriasis, elephantiasis, hypertrichosis, and freckles. 2. On the other hand, the following accidents may result from the use of the X rays: Dermatitis of varying severity, sometimes followed by abscesses and necrosis, alopecia, pigmentation, and desiccation of the epidermis.

Inoculation of Animals with Syphilis.—According to the British Medical Journal for September 30th, two recent writers state that they have successfully inoculated animals with syphilis. These results, if not conclusive, says the Journal, are of interest. Van Neissen (Wiener medicinische Wochenschrift, Nos. 11 to 14, 1899), from material obtained from condylomata and from the blood of syphilitic patients, asserts that he has cultivated a bacillus on agar and bouillon. This bacillus resembles sometimes that described by Lust-

The eighth volume of this valuable work on surgery contains the chapters devoted to the consideration of the diseases of the mesentery, pancreas, spleen, liver, gall bladder, rectum, and kidney. The first section, on the mesentery, pancreas, and spleen, is the least novel and interesting, simply because so little is as yet known of the causes entering into the pathological changes in these organs which become of surgical interest. A recent step forward in the study of the complex and interesting condition known as hemorrhagic pancreatitis and fat necrosis has not been dwelt upon by the author of the section in so full a manner as the results in the artificial production of the lesions of fat necrosis would warrant, and bacterial infection in these cases is of much less constant occurrence than the text indicates. The chapter by Faure on the surgical diseases of the liver is excellent and very complete. The discussion on the infectious origin of gallstones is completely in accord with the latest views on the subject. The operative procedures described for the removal of stones from the gall bladder, for abscesses of the liver, and for echinococcus cysts are refreshingly accurate and up to date. The best chapter in the volume, however, is that by Albarran, on the surgery of the kidney. The author has long been known as one of the most original and ingenious of the living generation of Parisian surgeons, and his opportunities as assistant to Guyon have been very great. The fruits of this training can be seen in the clear and practical way in which the various details of the subject are presented. The chapter on the examination of the kidney is very thorough and, although it is partly taken up with the description of a cystoscope adapted from those of Casper and Nitz, yet justice is done to the work of others. The author rightly points out the untrustworthiness of any judgment of the permeability of the kidney based on observation of the time required for the exertion of methylene blue injected subcutaneously, but he ignores the peculiarly valuable and suggestive work recently carried on in Germany on the very constant reduction of the freezing point of the blood in all cases of kidney insufficiency, a matter which promises much for the future study of the relations between the substances retained in the blood on the one hand and the function of the kidney on the other. In the rest of the subject there is less opportunity for an especially original treatment, but throughout the same careful, scientific method is pursued, and no point of value is omitted.

The third volume of Progressive Medicine is exceedingly interesting and of much value. It contains sections upon diseases of the thoracic viscera, the skin, and the nervous system and upon obstetrics. In all of these the editing and the recording of recent advances have been well done and the chapters are readable throughout. It has been urged as concerns this work that its disadvantage as compared with others of the "annual" class lies in the subscriber's getting his report piece-meal instead of its being in one dose as of yore. We begin to regard the "disadvantage" as an advantage, however, for not only would it seem to make for greater care in preparation, but certainly one may with pleasure read, quarterly, a book of reasonable dimensions and probably will] who is dismayed by the very bulk of a volume within whose covers is recorded a whole year's work.

Owing to a curious error, the volume before us has been numbered the sixth in the series. As a matter of fact it is the seventh volume of this admirable System we are now called upon to notice. Since the error is present both within the volume and upon its binding, unfortunate confusion can scarcely fail to result.

The seventh volume continues the study of cardiac diseases so ably begun in the sixth. Right-sided valvular lesions is the title of the first chapter. Following this, angina pectoris is exhaustively and most interestingly presented.

The next section of the work discusses diseases of

This manual is intended chiefly for students, and covers the field usually occupied by most of our college curricula. It will be found a succinct yet lucid textbook, covering favorably with others of its class. It describes the physical properties as well as the physiological action of drugs, together with their therapeutic uses.

The volume concludes with a chapter on toxicology and other subjects, such as prescription-writing, medical Latin, pharmacy, and practical anesthesia. A table of doses, poisons, antidotes, and incompatibilities, with a general index, completes the work.

The two former editions of this little book appeared under the title of Nursing in Abdominal Surgery and Diseases of Women. Its present name more correctly expresses the aim of the author. The writer has devoted much of her space to expounding the latest ideas on aseptic surgery, together with the subjects of disinfection, sterilization, the preparation of ligatures, sutures, and dressings, and the management of surgical complications. An appended chapter, prepared by Miss Sarah H. Janvier, on the dietary of the sick greatly enhances the value of the work.

This, the second edition, has been greatly enlarged by the addition of many of the newer remedies. The essential features of the work consist in a compilation of the "favorite prescriptions" of various physicians which have from time to time appeared in Leonard's Illustrated Medical Journal. The formulae would perhaps be more available if the diseases for which they are intended were arranged alphabetically.

Books, Etc., Received.

Practice of Medicine. A Manual for Students and Practitioners. By George E. Malsbary, M. D., Assistant to the Chair of Practice, Medical College of Ohio, University of Cincinnati, etc. Series edited by Bern B.
MISCELLANY. [N. Y. Med. Jour.]

Transactions of the Association of American Physicians. Fourteenth Session held in Washington, May 2, 3, and 4, 1899. Volume XIV.

Difficult Points in Gynecologic Diagnosis. By Wilmer Krusen, M. D., of Philadelphia. [Reprinted from the Philadelphia Medical Journal.]

The Cause of Uterine Retrodisplacements. By Wilmer Krusen, M. D. [Reprinted from the American Gynecological and Obstetrical Journal.]

The Failure of Antitoxine in the Treatment of Diphtheria. By J. Edward Herman, M. D., of Brook-lyn. [Reprinted from the Medical Record.]

The New Local Anesthetic “Nirvanin.” By August Luxenburger, M. D., of Munich. [Reprinted from the Philadelphia Monthly Medical Journal.]

The Evolution of Scientific Medicine. By Louis Faugères Bishop, M. D. Read before the Section of Medicine, New York Academy of Medicine.

Infection in the Toilet. By Martin F. Engman, M. D., of St. Louis. [Reprinted from the Medical Review.]

MISCELLANY.

The New York Skin and Cancer Hospital.—It is announced that Dr. L. Duncan Bulkley will give a course of clinical lectures on diseases of the skin, free to physicians, on Wednesday afternoons, beginning on November 1st.

The Laboratory Committee of the American Public Health Association has prepared the following provisional programme for the meeting in Minneapolis on October 30th: Introductory address by the honorary chairman, Dr. W. H. Welch, of Johns Hopkins University; Dr. W. C. Bissell, Buffalo—Experiments on the Infectiousness of Clothing; Dr. E. R. Baldwin, Saranac Lake—Recent Laboratory Work on Tuberculosis; Dr. H. W. Clarke, Lawrence, Massachusetts—Action of Massachusetts Water Supplies upon Lead; Dr. W. A. Copeland, Pittsburgh—Bacillus coli and Drinking Water; Dr. Floyd Davis, Des Moines—Relation of Water Investigation to Legal Controversy; Dr. R. G. Free-man, New York—Laboratory Studies on Bacteria and Milk Supply; Dr. G. W. Fuller—(1) Classification of Water Bacteria; (2) Standard Laboratory Methods; Dr. F. Ferguson, New York—Etiology of Disease and its Geographical Distribution; Dr. Adolph Gehrmann, Chicago—(title not given); Dr. Hibbert Hill, Boston—Branching Forms of Diphteria Bacilli; Dr. G. W. Whipple, Brooklyn—The Observation of Odors as an Essential Part of Water Analysis; Dr. Wyatt Johnston, Montreal—Personal Experience in Disinfection; Dr. E. O. Jordan, Chicago—Notes on Bacterial Water Analysis; Dr. L. P. Kinnicut, Worcester—Laboratory Studies on the Disposal of Sewage; Dr. J. J. Mackenzie, Toronto—(title not given); Dr. F. G. Novy, Ann Arbor—(1) Oxalate Blood and Plasma; (2) (title not given); Dr. W. H. Park, New York—Preparation of Antistreptococcic Serum; Mrs. Ellen H. Richards, Boston—Educational Institutions in Relation to Expert and Commercial Work; Dr. H. L. Russell, Madison, Wisconsin—Gas-producing Water Bacilli of Non-colon Types; Dr. W. R. Stokes, Baltimore—Bacillus coli and Drinking Water; Dr. F. F. Wesbrook, Minneapolis—Varieties of Diphteria Bacilli.

The Wayne County (Michigan) Medical Society’s Movement in Favor of Inter-State Reciprocity has been endorsed by the Utah State Medical Society, which has appointed a committee to aid in the undertaking. The committee consists of Dr. Charles Pinckney Hough, Dr. E. V. Silver, and Dr. H. D. Niles.

The American Public Health Association.—The twenty-seventh annual meeting will be held in Minneapolis on October 31st and November 1st, 2d, and 3d, under the presidency of Dr. Henry Mitchell, of Ashbury Park, New Jersey. The executive committee has selected the following subjects for discussion: The Polli-
tion of Water Supplies; The Disposal of Garbage and Refuse; Animal Diseases and Animal Food; Car Sanitation; Steamship and Steamboat Sanitation; The Epidemiology of Yellow Fever; The Relation of Forestry to the Public Health; Demography and Statistics in their Sanitary Relations; The Cause and Prevention of Infectious Diseases; Public Health Legislation; The Cause and Prevention of Infant Mortality; The Period during which each Contagious Disease is Transmissible, and the Length of Time for which each Patient is Dangerous to the Community; Sanitation, with Special Reference to Drainage, Plumbing, and Ventilation of Public and Private Buildings; Some Method of International Arrangement for Protection against the Transmission of Infectious Diseases; Disinfectants; To Examine into the Existing Sanitary Municipal Organizations of the Countries belonging to the Association, with a View to Report upon those most Successful in Practical Results; Laboratories; To Define what Constitutes an Epidemic; A National Leper Home; The Revision of the Classification of Diseases; and Dangers to the Public Health from Illuminating Gas Leakage.

The special committees are:

Publication Committee.—Dr. C. O. Probst, of Columbus, Ohio; Dr. Josiah Hartzelle, of Canton, Ohio; and Dr. Irving A. Watson, of Concord, New Hampshire.

On the Pollution of Water Supplies.—Dr. Charles Smart, of the United States Army, Washington; George W. Fuller, Esq., of New York; Dr. Wyatt Johnston, of Montreal; Dr. José Ramírez, of Mexico; Dr. A. C. Abbott, of Philadelphia; Professor Floyd Davis, of Des Moines, Iowa; Dr. Henry Leffman, of Philadelphia; and Dr. John L. Leal, of Paterson, N. J.

On the Disposal of Garbage and Refuse.—Mr. Radcliffe H. Herling, C. E., of New York; Dr. Benjamin Lee, of Philadelphia; Dr. J. A. Beaudrey, of Montreal; Dr. José Ramírez, of Mexico; and Mr. W. C. R. Colquhoun, of Wilmington, Delaware.

On Animal Diseases and Animal Food.—Dr. D. E. Salmon, of Washington; Dr. Henry N. Avery, of Minneapolis; Professor José L. Gomez, of Mexico; Dr. C. N. Hewitt, of Red Wing, Minnesota; and Dr. Henry M. Bracken, of Minneapolis.

On Car Sanitation.—Professor S. H. Woodbridge, of Boston; Dr. Granville P. Conn, of Concord, New Hampshire; Dr. J. J. Kinyoun, of the United States Marine-Hospital Service, Washington; Dr. Domingo Orvañanos, of Mexico; and Dr. John N. Hurty, of Indianapolis.

On the Epidemiology of Yellow Fever.—Dr. H. B. Horbeck of Charleston, South Carolina; Dr. Felix Formento, of New Orleans; Dr. George M. Sternberg, of the United States Army, Washington; Dr. Eduardo Liceága, of Mexico; Dr. Manuel Carmona y Valle, of Mexico; Dr. Samuel R. Olliphant, of New Orleans; Dr. Walter Wyman, of the United States Marine-Hospital Service, Washington; and Dr. Alvah H. Doty, of New York.

On Steamship and Steamboat Sanitation.—Dr. Frederick Montizambert, of Ottawa, Ontario; Dr. Albert L. Gihon, of the United States Navy, New York; Dr. S. H. Durgin, of Boston; and Dr. Alvah H. Doty, of New York.

On the Relation of Forestry to the Public Health.—Professor William H. Brewer, of New Haven; Dr. Juan Breña, of Zacatecas, Mexico; Dr. John W. Coventry, of Windsor, Ontario; and Dr. James B. Eagleson, of Seattle, Washington.

On Demography and Statistics in their Sanitary Relation.—Dr. Cressy L. Wilbur, of Lansing, Michigan; Dr. Charles V. Chapin, of Providence, Rhode Island; Dr. John S. Fuller, of Baltimore; Dr. Frederick Bracken, of Minneapolis; and Dr. A. G. Young, of Augusta, Maine.

On the Cause and Prevention of Infectious Diseases.—Dr. Peter H. Bryce, of Toronto, Ontario; Dr. George M. Sternberg, of the United States Army, Washington; Dr. J. J. Kinyoun, of the United States Marine-Hospital Service, Washington; Dr. Jesús E. Monjarás, of San Luis Potosi, Mexico; Dr. C. N. Hewitt, of Red Wing, Minnesota; Dr. A. Walter Suiter, of Herkimer, N. Y.; Dr. Wyatt Johnston, of Montreal; and Dr. Frank W. Wright, of New Haven.

On Public Health Legislation.—Dr. Henry P. Walcott, of Cambridge, Massachusetts; Dr. J. N. McCormack, of Bowling Green, Kentucky; Dr. Henry B. Baker, of Lansing, Michigan; Dr. Samuel R. Olliphant, of New Orleans; Dr. Benjamin Lee, of Philadelphia; Dr. U. O. B. Wingate, of Milwaukee; Dr. C. O. Probst, of Columbus, Ohio; Dr. E. P. Lachappele, of Montreal; Dr. Gregorio Mendizábal, of Orizaba, Mexico; Dr. J. A. Albright, of Nashville; Dr. James Patterson, of Winnipeg, Manitoba; and Dr. Henry D. Holton, of Brattleboro, Vermont.

On the Period during which Each Contagious Disease is Transmissible and the Length of Time for which Each Patient is Dangerous to the Community.—Dr. Eduardo Liceága, of Mexico; Dr. John L. Leal, of Paterson, N. J.; Dr. Fernando Lopez, of Mexico; and Dr. J. J. Kinyoun, of the United States Marine-Hospital Service, Washington.

On the Cause and Prevention of Infant Mortality.—Dr. Ernest Wende, of Buffalo; Dr. Baxter T. Smeler, of Albany; Dr. John W. Coventry, of Windsor, Ontario; and Dr. Emanuel Skeiton, of Querétaro, Mexico.

On Sanitation, with Special Reference to Drainage, Plumbing, and Ventilation of Public and Private Buildings.—Mr. John Mitchell, of New York; Dr. Miguel Marquez, of Chihuahua, Mexico; Mr. Crosby Gray, of Pittsburgh; Dr. James Campbell, of Hartford, Connecticut; and Dr. C. Hampson Jones, of Baltimore.

On Some Method of International Arrangement for Protection against the Transmission of Infectious Diseases.—Dr. Stephen Smith, of New York; Dr. Frederick Montizambert, of Ottawa, Ontario; Dr. J. J. Kinyoun, of the United States Marine-Hospital Service, Washington; Dr. Eduardo Liceága, of Mexico; and Dr. Felix Formento, of New Orleans.

On Disinfectants.—Professor F. C. Robinson, of Brunswick, Maine; Dr. Wyatt Johnston, of Montreal; Dr. Alvah H. Doty, of New York; Dr. George M. Sternberg, United States Army, Washington; Dr. Eduardo Liceága, of Mexico; and Dr. H. W. Hill, of Boston.

On Existing Sanitary Municipal Organizations of the Countries belonging to the Association, with a View to Report upon those Most Successful in Practical Results.—Dr. Charles V. Chapin, of Providence, Rhode Island; Dr. Domingo Orvañanos, of Mexico; Dr. John Sweetland, of Ottawa, Ontario; and Dr. W. C. Woodward, of Washington.

On what Constitutes an Epidemic.—Dr. U. O. B. Wingate, of Milwaukee; Dr. Benjamin Lee, of Philadelphia; Dr. Charles V. Chapin, of Providence, Rhode Island; Dr. Frederick Montizambert, of Ottawa, Ontario.

On a National Leper Home.—Dr. H. M. Bracken, of Minneapolis; Dr. Henry B. Horbeck, of St. Paul; Dr. José Ramírez, of Mexico; Dr. C. P. Wilkinson, of...
New Orleans; and Dr. George E. Couthard, of Frederick, New Brunswick.

On the Revision of the Classification of Diseases.—For the United States: Dr. S. W. Abbott, of Wakefield, Massachusetts; Dr. C. L. Wilbur, of Lansing, Michigan; and Dr. A. G. Young, of Augusta, Maine. For Canada: Dr. Peter H. Bryce, of Toronto, Ontario; Dr. E. P. Lachapelle, of Montreal; and Dr. E. Pelletier, of Montreal. For Mexico: Dr. Eduardo Liceaga, of Mexico; Dr. Jose Ramirez, of Mexico; and Dr. Jesus E. Monjaras, of San Luis Potosi, Mexico.

On Dangers to the Public Health from Illuminating Gas Leakage.—Dr. Samuel H. Dargin, of Boston; Mr. William Paul Gerhard, C. E., of New York; and Mr. W. W. Hughes, of Montreal.

On Laboratories.—Dr. J. G. Adami, of Montreal; Dr. A. C. Abbott, of Philadelphia; Dr. W. G. Bissell, of Buffalo; Dr. Hermann Biggs, of New York; Dr. E. C. Baldwin, New Jersey State board of health; Dr. E. R. Baldwin, of Saranac Lake, N. Y.; Dr. George Blumer, of Albany; Mr. B. Beade Bolton, of Princeton, N. J.; Dr. M. Carmona y Valle, of Mexico; Dr. Richard Cabot, of Boston; Dr. H. W. Clark, Massachusetts State board of health; Dr. H. W. Conn, State Experiment Station, Connecticut; Dr. W. L. Coplin, of Philadelphia; Dr. W. T. Councilman, of Boston; Dr. T. B. Carpenter, of Buffalo; Dr. W. Copeland, of Pittsburgh; Dr. E. A. Floyd Davis, Iowa State board of health; Dr. E. A. de Schweinitz, of Washington; Dr. W. L. Drown, of Lehig University; Dr. E. K. Dunham, of New York; Dr. H. C. Erust, of Boston; Dr. R. G. Freeman, of New York; Dr. Adolph Gehrmann, of Chicago; Dr. Frank Ferguson, of New York; Dr. Charles Harrington, of Boston; Dr. P. F. Harvey, of the United States Army; Dr. L. Hektoen, of Chicago; Dr. Hibbert Hill, of Boston; Dr. P. H. Hiss, of New York; Dr. Elmer G. Horton, Ohio State board of health; Dr. J. H. Huddleston, of New York; Dr. D. D. Jackson, of Brooklyn; Dr. Wyatt Johnston, of Montreal; Dr. E. O. Jordan, of Chicago; Dr. L. P. Kinnicut, of Worcester, Massachusetts; Dr. J. J. Kinyoun, of the United States Marine-Hospital Service; Dr. S. S. Kneass, of Philadelphia; Dr. Edwin Klebs, of Chicago; Dr. Henry Leffmann, of Philadelphia; Dr. J. H. Linsley, Vermont State board of health; Dr. Jerome Lartigan, of New York; Dr. J. L. Miller, of Chicago; Dr. J. W. MacCallum, of Boston; Dr. J. MacFarland, of Philadelphia; Dr. J. J. Mackenzie, Ontario provincial board of health; Dr. J. W. Mallet, of Charlottesville, Virginia; Dr. W. G. Mitchell, Denver board of health; Dr. V. A. Moore, of Ithaca; Dr. F. G. Noye, of Ann Arbor, Michigan; Dr. G. H. Nuttall, of Cambridge, England; Dr. W. H. Park, of New York; Dr. Herbert Pease, of Buffalo; Dr. Jay Perkins, of Providence, Rhode Island; Dr. T. M. Prudden, of New York; Dr. M. P. Ravenel, of Philadelphia; Dr. Walter Reed, of United States Army medical department; Mrs. Ellen H. Richards, Massachusetts Institute of Technology; Dr. Mark W. Richardson, of Boston; Dr. F. C. Robinson, Maine State board of health; Dr. H. L. Russell, Wisconsin State board of health; Dr. W. T. Sedgwick, Massachusetts State board of health; Dr. H. E. Smith, Connecticut State board of health; Dr. Theobald Smith, of Boston; Dr. Charles Smart, of the United States Army medical department; Dr. E. K. Sprague, of the United States Marine-Hospital Service; Dr. Alfred Stengel, of Philadelphia; Dr. George M. Sternberg, of the United States Army medical department; Dr. W. R. Stokes, of Baltimore; Dr. Gardner T. Swartz, of Providence, Rhode Island; Dr. E. L. Trudeau, of Saranac Lake, N. Y.; Dr. Victor C. Vaughan, of Ann Arbor, Michigan; Dr. G. L. Weaver, of Chicago; Dr. W. H. Welch, of Baltimore; Dr. F. F. Wesbrook, Minnesota State board of health; Dr. G. C. Whipple, Water Department, Brooklyn; Dr. Ezra H. Wilson, of Brooklyn; Dr. L. B. Wilson, Minnesota State board of health; Dr. R. A. Withhaus, of New York; and Dr. J. H. Wright, Massachusetts General Hospital.

Chairman of the Local Committee of Arrangements—Dr. Richard O. Beard, of Minneapolis.

The North Hudson County (New Jersey) Medical Society.—At the first annual meeting, held on September 25th, officers for the ensuing year were elected as follows: President, Dr. John P. Henry, of Jersey City; vice-president, Dr. Max Hecht, of West Hoboken; secretary and treasurer, Dr. Louis E. Poole, of West Hoboken.

Diploma Mills in Illinois.—The supreme court of Illinois on the 16th inst. revoked the charter of the Independent Medical College, of Chicago. For information concerning the steps taken to remove from the legally chartered corporations of Illinois this notorious "diploma mill," see the Journal of the American Medical Association, March 12, 1898, page 630 (letter to the attorney-general).

After obtaining further proof of the wholesale sale of "diplomas" by this institution, the attorney-general brought suit in the circuit court of Cook County to have the charter of the "college" revoked. After hearing the evidence, the court, on February 15, 1899, entered a judgment of ouster. The faculty of the college made no defense, but took an appeal to the supreme court simply to gain time.

The decree of the circuit court apparently in no manner whatever interfered with the sale of diplomas. On the contrary, the "faculty" of the institution made strenuous efforts to confer as many degrees as possible from the college, which was rapidly approaching dissolution, and to that end "lowered the scale of prices" and made doctors of medicine empowered to practise in Michigan, Kansas, Texas, and elsewhere, of all who applied and presented a fee.

The sale of these diplomas has continued to the present time. Early in the month the State board of health purchased one in Fort Worth, Texas, for twenty dollars. The transaction, however, was arranged in Champaign, Illinois, through a licensed physician whom the board has since summoned to appear and show cause why his certificate should not be revoked for unprofessional and dishonorable conduct. The "physician" in this case, whom the college required to "show evidence of qualifications," was a young law student of whom the sole requirement demanded was a tender of the necessary fee in advance.

As the ies of October rapidly drew near, the "faculty" began to realize that he and the Independent had come to the parting of the ways. In August, therefore, the institution "became affiliated" with the "Metropolitan Medical College," another "legally chartered medical college," the charter having been issued by the secretary of state under the provisions of th act of 1872. Just what this institution proposes to do is clearly shown in the subjoined extracts from a letter sent out from the headquarters of the dying Independent:
Dear Friends:

Graduates of the Independent Medical College and other advanced practitioners will be glad to know that the enemies of that institution have so far failed to break it up. Since 1896 they have assailed it, and by misrepresentation, vituperation, and expensive proceedings in court have endeavored to overthrow it. But it still stands and with unabated energy and undiminished success it is prosecuting its work of reform to-day. Instead of regarding as a misfortune the opposition it has met from its foes, it regards it as an evidence that its position as an institution set for the overthrow of medical monopoly, and the granting of liberty to all qualified practitioners to pursue their profession unhindered, is right. The more determined the opposition, the more convincing it regards the proof that its work is needed.

But the world moves, and we must not rest satisfied with past achievements. We must be prepared to meet other and greater emergencies. We must lay the foundation for a firmer footing for competent and experienced physicians, and for greater liberty to the people to employ whatever doctor of whatever school they choose.

The Independent and the Metropolitan Medical Colleges each have their distinctive fields of work. There are many young men and women of ability who could not meet the heavy expense of a medical monopoly college course, but, according to our method and with the assistance of a preceptor at home, could secure a better practical equipment for practice than that possessed by thousands who have graduated from old-line schools. The Independent has met and will continue to meet the necessities of that class.

Then, again, there are thousands of experienced practitioners who do not so much require more knowledge as they require the authority and privilege to use the knowledge and ability they already possess. They are competent; their work has proved their efficiency and being justly entitled to a standing before the public not second to any class of physicians, it is the work of the Metropolitan Medical College to accomplish this object, and with this end in view it has adopted the highest standard of any medical college in the country.

Post-graduate courses are now being given practitioners at the Metropolitan Medical College. Full particulars sent on application.

Very truly yours,

Jas. Armstrong.

One cannot but admire the naïveté with which the alumni of the Independent are importuned to get under the shelter of the Metropolitan. There is little doubt that the Metropolitan will be conducted on the same lines as the Independent. If this is the case, its career will be exceedingly brief. Under the provisions of a statute which came into force July 1, 1899, the attorney-general may file a bill in chancery in the name of the people of the State of Illinois against any corporation authorized to confer degrees, diplomas, or other certificate or certificates of qualifications in the science of medicine, pharmacy, or dentistry which conducts a fraudulent business or abuses, misuses, or violates the terms of its charter, in any court having jurisdiction of the corporation and subject matter of such bill, for an injunction to restrain said corporation from conducting its fraudulent business or abusing, misusing, or violating the terms of its charter, and also for the dissolution of said corporation, "and thereupon it shall be the duty of the court in which said bill is filed to grant such injunction and to hear and determine the same as in other cases in chancery. And provided, further, that this act shall apply to schools, colleges, or universities which now are or may hereafter be licensed in this State, notwithstanding any provisions that may exist in their charters."

The enactment of this law is due to the persistent efforts of the secretary and attorney of the State board of health, exercised during the entire legislative session of 1899. Much praise, however, in this connection must be accorded to the governor of the State, without whose aid the labor of the secretary and attorney would have been futile.

The following extract from the decision of the supreme court will be of interest:

This is a proceeding by information, in the nature of a quo warranto, brought in the circuit court of Cook County, February term, 1898, by the people, on the relation of the attorney-general, against the Independent Medical College, a corporation of Chicago, to forfeit its franchise or charter. The corporation was chartered in 1896, having as its object the establishment of an institution of learning and for the purpose of promoting mental and physical culture, and for teaching branches taught in medical colleges generally, with power to grant diplomas and confer degrees. The information charges that the corporation is conducted for pecuniary profit; that it confers degrees and issues diplomas for a price, without regard to the qualification or fitness of the applicant to practise medicine; that in some cases no examination whatever is required, and degrees are conferred upon persons wholly unfit and incompetent; that in one case, specifically alleged, a diploma or license to practise medicine and surgery was granted for the price of twenty-five dollars, the applicant never having been a student of medicine or surgery. It is further charged that the corporation "is a mere diploma mill, designed wholly for issuing diplomas to practise medicine, for a consideration, to persons wholly unqualified for such practice."

The respondent filed a plea to the information, denying its general allegations, and averring that it had not resorted to wrongful or unlawful methods in conferring degrees as a means of profit to its incorporators, and that it had not issued diplomas to persons wholly incompetent to practise medicine. To this plea the attorney-general filed a replication averring that the defendant had usurped and misused, and did now usurp and misuse its liberties, privileges, and franchises, and tendering issue. Issue being joined, the cause was heard by the court without jury, upon the pleadings and evidence taken. The court found the defendant guilty as charged, and rendered judgment that the Independent Medical College be ousted and excluded from the exercise of all its corporate privileges and franchises under its articles of incorporation. The defendant prosecuted this appeal.

This information charges the grounds upon which a forfeiture of the defendant's charter is urged, with all the certainty required by the rules of civil pleading; and those grounds, if sustained by the proof, were sufficient, as held in People ex rel. vs. Illinois Health University, 166 Ill., 171, where we said, among other
things: "It is not consistent with the public policy of a State which enacts stringent laws for the preservation of the public health and for the protection of its people from quacks and ignorant pretenders to a knowledge of the science of medicine and surgery to authorize or permit a pretended 'health university' to turn any one, whether known or unknown, qualified or unqualified, into a doctor of medicine, armed with a diploma and degree, as one qualified to heal the sick, who may answer its prescribed list of questions and pay its prescribed fee." And it was there held, for such abuse and misuser the charter of the corporation should be revoked, citing Edgar Collegiate Institute vs. People, 142 Ill., 363. The health university, respondent in this case, was practically the same institution as the one now before the court, and the only material difference in that case and this is that there the ouster was upon a demurrer to the information, whereas here there was a trial upon the issues of fact.

Without an extended analysis or weighing of the testimony introduced upon the trial as it appears in this record, we have no hesitancy in saying that it fully justified the finding and judgment of the court below. In fact, it is sufficient to establish the guilt of the defendant, as charged in the information, beyond a reasonable doubt, and would have justified not only the forfeiture of the charter, but the infliction of a fine upon the parties guilty of the abuses. The judgment of the circuit court will be affirmed.

An Attack on the Oculists of New York.—The following article, concerning which we have something to say in our editorial columns, appeared in the Evening Post last Saturday.

There is a tacit understanding between some practitioners who "give their services free" at the free ophthalmic hospitals and certain opticians for the division of profits on the glasses prescribed by one and sold by the other to the indigent patient. According to a prominent Maiden Lane optician the most flagrant impositions are practised upon the poor. "I have incontrovertible proof of the cases in point," said the optician. "The leading professors at these free institutions are salaried and above the taint of reproach in professional ethics; but nine tenths of the staff 'donate' their professional services, presumably for the practice. Many in reality go into it as a money-making business, and sometimes the profits come quick and fast, where hundreds of patients are prescribed for in a single day.

"My eyes were first opened to the practice between the oculist and optician when a neighboring optician one day came over to me and asked if I could read some hieroglyphics on a piece of paper which he handed to me. I studied them for a while, and failed to make anything out of them. The 'prescription,' as it was called, had been given that morning to a woman patient at a well-known clinic, and she duly presented it, to be filled, to the optician to whom she was directed. She first asked how much the glasses would cost, and was told $4.50 for a steel frame. This sum was beyond the woman's means, and she said so to the optician as she left his place of business. She then betook herself to the man who came over to ask me to decipher the alleged prescription. He was a relative, and she knew he would fit her out as cheaply as possible. In the first place she went credulously to the optician recommended, because it was impressed upon her that he could be trusted implicitly, and that she should go nowhere else.

"After some consultation, I dictated a letter to the clinic, asking for an explanation of the prescription for the man who was asked to fill it. The oculist involved replied that it was a cipher, and that he was obliged to use it to safeguard his patients from going to untrustworthy opticians. As the man whose signature was appended to the letter was one of the best and most reputable known to the profession in New York, the scheme at the bottom was rather transparent. Had he known the patient was so poor, the writer stated, he would have helped her to get the glasses as cheaply as possible. Upon further inquiry he found that the cipher prescription informed the optician of the patient's circumstances, as deduced from the regular questions put before a patient will be accepted for treatment at the hospital. The new dispensary law is supposed to prevent any but the poor from benefiting from the free hospital treatment, but we discovered that some of the oculists are just as unscrupulous here, for they let no chance of obtaining a commission go by, and it is all the better for their pocketbooks if the suspicion that the patient is fairly well off prove grounded when the price of the glasses is paid. Thirty and thirty-five per cent. of the profits is the usual commission asked and given. By the way, the pair of glasses in question cost $1.25, so the remaining $3.25, had the woman purchased them from the oculist as her copartner in business, would have been divided between the two. When glasses costing $4, $5, $6, and $7 are prescribed in large numbers daily, you see the commissions figure up nicely.

"Some oculists insist on receiving the entire profits, and we have discovered that certain opticians agree to this, depending upon future breakages and duplicate orders to reimburse them. Another scheme which has come to our attention since we began to be on the lookout for such things is this: An oculist will give a patient a slip of paper with a number on it, and direct him or her to go to a certain optician. After her departure he telephones the optician the prescription, and the patient is thus prevented from going to any one except the man to whom the number means something.

"Here is a letter which I received a few days ago from an oculist, evidently young in the business, who forgot to make his arrangements as to commissions with his optician first. Inclosed with the prescription is this note, in which the writer says he supposes I will allow him the regular commission on all prescriptions which he sends me to fill. That note fell into the wrong hands, or rather the right hands, as I have been lying in wait for a long time for just such a piece of documentary evidence to support me in a crusade which the reputable opticians are about to institute against the practice in question. It has reached no further stage than the same kind of system once did between medical practitioners and druggists, which is now practically ended, thanks to the stand taken by the medical fraternity as a body when their attention was once aroused to the extent to which the practice was carried on. We hope to accomplish the same result by watching and exposing every one who makes use of the guise of charity to extort money from the poor and lower the professional standard of ethics."

Vaccination of British Soldiers against Typhoid.—According to reports in the daily press, the British soldiers sailing for Africa have been urged to submit to inoculation with antityphoid virus, and a large number have done so.

DR. BOSTON'S ARTICLE ON SPECIMEN CASTS FOUND IN URINE.
Original Communications.

HOW TO PRESERVE AS PERMANENT SPECIMENS CASTS FOUND IN URINE.

By L. NAPOLEON BOSTON, M.D.,
BACTERIOLOGIST TO THE PHILADELPHIA HOSPITAL; INSTRUCTOR IN OBSTETRICS IN THE MEDICO-CILIURGICAL COLLEGE, PHILADELPHIA.

The object of this paper is not to review or to deal in any way with the various methods recommended for the mounting of casts as permanent specimens, but to describe the method which has proved satisfactory in the hands of the writer. Generally speaking, all crystalline substances found in urine can be preserved in Canada balsam after allowing them to dry on a slide or cover glass. However, specimens thus mounted are likely to become cloudy in from a few weeks to two years. Shreds of tissue, parasites and their ova, are well preserved when mounted in glycerin, as are unstained bacteria and fungi.

It is far more difficult to make satisfactory mounts of casts, since their general characteristics are so readily destroyed by evaporation or the slightest pressure; and their basement membrane, so to speak, is of such chemical composition as to dissolve when brought in contact with the various mounting media. The ability to destroy all bacteria, especially those capable of producing gas, is of equal importance in selecting a mounting medium. Where the field becomes cloudy casts integrate, or air bubbles appear within a few days or weeks after a specimen is mounted. These changes are commonly due to the development of bacteria. A mixture of the following will be found capable of preserving all forms of casts: Liquor acidi arsениosi (U. S. P.), one fluid ounce; salicylic acid, half a grain; glycerin, two fluid drachms. Warm slightly until solution is effected, when add acacia (whole tears), and again warm until solution is saturated; after subsidence, decant clear supernatant liquid. A drop of formalin (forty per cent.) may be added to this mixture if desired.*

After all ordinary precautions as to cleanliness are taken in securing the urine, a bottle, previously cleaned, is partially filled, corked tightly, and allowed to stand in a cool place until a precipitate collects at the bottom of the liquid. Decant the supernatant urine, add an equal quantity of distilled water to the precipitate, and allow to stand until it collects again at the bottom of this liquid. (If a few drops of chloroform are added, urine thus obtained can be kept for days without any change in the casts.) The precipitate is lifted by means of a pipette, and a small drop of the thickest of this sediment is placed on the centre of the slide and carried to the microscope, where it can be viewed under a low power. If casts are present, it is evaporated nearly to dryness, when a drop of the above-described medium is added by means of a glass rod to the centre of the drop of urine, and it will be noticed that there is no tendency for these substances to mix; the urine completely surrounds the drop of medium, and in order to get an equal distribution of casts throughout the field, it is necessary to carry a fine needle from the outer margin of the urine to the centre of the medium until the two substances show no tendency to separate, care being taken lest air bubbles are produced. A cover glass is moistened by the breath and then allowed to fall gently on the specimen. The slightest pressure, or the application of heat, is usually destructive to casts. The slide is now put in a cool place for a few hours, in order that hardening may be complete. A permanent ring of zinc-white has been shown to be of value in the preservation of these specimens. The accompanying plates were sketched from specimens that had been mounted two years and a half, and show perfectly every feature possessed by casts studied from the same urine after the usual methods employed.

THE MEDICAL HISTORY OF SIR WALTER SCOTT.

By Professor ROBERTS BARTHOW, M.D., LL.D., PHILADELPHIA.

To vary a little the medical monotonv of the dog days, I took up one day Lockhart's Life of Sir Walter Scott. Besides being among the first of great biographical works, the life of Scott must have perennial interest for the physician because of the remarkable incidents in the medical history of its subject. As Lockhart, the biographer, was Scott's son-in-law, he had the best opportunity for ascertaining the real facts, and he possessed in considerable degree that narrative skill which Boswell exhibited in such supreme measure in his Life of Johnson.

Sir Walter Scott, when fully grown and developed into manhood, was physically an admirable specimen of the border Scotsman—with one exception: he was lame in the right leg. There can be little doubt that this lameness was due to the infantile form of "poliomyelitis anterior," or, as it is commonly called, "infantile paralysis." It is a curious circumstance that the two great English poets of the first part of this century should both have been lame, and from the same cause. When Scott and Byron met in London at the house of Murray, the publisher, the conversation between them concerned, we may suppose, every topic other than their mutual lameness, since we have no record of any humorous or serious allusion to their respective physical limitations. Byron guarded his secret with an exquisitely sensitive apprehension of ex-

* W. T. England, Ph. D., druggist to the Philadelphia Hospital, regards this as an easy method of preparation.
posure, and permitted no reference to it even by his most intimate friends, and was quick to resent even a look of inquiry directed toward his deformity. During Byron's life, therefore, nothing could be ascertained of the nature of his lameness. It is narrated, however, that in a few hours after his death an inquisitive friend stole into the room where the poet's body lay, and, quickly removing the covering, saw that the deformity consisted in a shriveling of both legs. "The body of Apollo and the legs of a Satyr."

Scott was never reticent about his lameness, and in an interesting autobiographical fragment gave the clinical history of his ailment. He says: "I showed every sign of health and strength until I was about eighteen months old. . . . In the morning I was discovered to be affected with the fever that often accompanies the cutting of large teeth. It held me three days. On the fourth, when they went to bathe me as usual, they discovered that I had lost the power of my right leg. . . . There appeared to be no dislocation or sprain; blisters and other topical remedies were applied in vain. When the effects of regular physicians had been exhausted without the slightest success, my anxious parents, during the course of many years, eagerly grasped at every prospect of eure which was held out by the empirics, or ancient ladies or gentlemen, who conceived themselves entitled to recommend various remedies, many of which were sufficiently singular." When he was four years old, he was sent to Bath, where he lived a year and "went through all the usual discipline of the pump room and baths, but he believed without the least advantage to his lameness." He was also treated by the celebrated electrical quack, Dr. Graham, who made a great parade of electric appliances, but he was not benefited in the least by the magnetic touch of the splendid quack, or by the electric current. Remak had not then appeared with galvanism, nor had Duchenne developed the new faradism. Indeed, nothing was then known of the methods now employed in the way of massage, movements, local electrization, etc., and still less of the pathological condition: the atrophy and degeneration of the multipolar cells of the anterior cornua of the spinal cord, and their connected fibres, the neurons. Of course, nothing was then known of the reactions of degeneration, the loss of faradize excitability, the retention of the galvanic reaction, and the ultimate extinction of response to all electrical excitation. Notwithstanding the poverty of their therapeutic resources, one measure was resorted to that we may well imitate.

Scott's grandfather was Dr. Rutherford, professor of medicine in the University of Edinburgh, and by his advice, besides going into the country to rough it, efforts were made to call into action the affected muscles by the will. This method consisted in placing bright objects, or things that the boy especially desired, in such a position that he could get them only by the most powerful efforts in which the affected members participated. By the persistent use of this plan of "natural exertion" there ensued a great gain in the power of the will over the muscles, and they increased in size and in the range of their actions until the limb ultimately became quite useful, although always lame.

This method of dominating the paralyzed and wasted muscles by the forebode action of the will is only possible in those cases in which a little voluntary control was still preserved. Some response to the will may be present, when the faradistic or interrupted galvanic currents have no longer any power to excite muscular contractions. That this was the case with Scott is shown by the results of the method of "natural exertion." As he writes in his autobiography: "My frame gradually became hardened with my constitution, and, being both tall and muscular, I was rather disfigured than disabled by my lameness. This personal disadvantage did not prevent me from taking much exercise on horseback and making long journeys on foot, in the course of which I often walked from twenty to thirty miles a day."

As his father's apprentice, Scott was introduced to the law, and "he put on the gown in June, 1792." He was early drawn off from the law into imaginative literature, when he produced those celebrated works on which his fame now rests. Although his authorship of the poems was never concealed, the great novels in which he attained the highest reach of his powers were published with a careful attempt to keep their creator's identity from the public, and with such success was this secrecy consummated that their author was called "the Great Unknown." In Edinburgh, however, the real facts were known to a great many, and throughout England were suspected by multitudes. He was the most interesting figure in the social life of the time.

He was an eminently handsome man, friendly and accessible. The king was his intimate personal friend, and the humblest peasant was sure of a kind reception. During his youth and early manhood, and while he was a student (apprenticed to the law) there was much dissipation among his associates, and in the society of Edinburgh generally. He says in his autobiography: "Convivial habits were then indulged among the young men of Edinburgh . . . to an extent now happily unknown" (vol. i, p. 118). As his reputation grew with the appearance of his poems and other great works, Scott became more and more in demand in the social life of his native city. He quickly rose into the position of the most eminent literary character of his time, and he possessed in the highest degree all social gifts and graces. It can not surprise us, therefore, that he became the most important personage in all social functions—at every dinner, at every champagne supper. When he was in London on several occasions, King George IV, then Prince Regent, "got up snug little dinners that will suit him"; at which the toasts were frequent and in bumpers; the fun ran high; the en-
Thusiasm was tremendous (vol. iii, p. 249). Although never intoxicated and an indefatigable worker, and for many years after childhood free from any illnesses, he could hardly fail to experience the usual results of wine-drinking, drinking of Scotch whisky, and improper feeding in all directions. When he approached middle life these indulgences bore their legitimate fruit. To quote his biographer: “For the first time since his childhood years Scott was visited with a painful illness, all nearly of the same kind continued at short intervals during more than two years.” The first serious alarm occurred toward the close of a “merry dinner party” in Castle Street (on the 5th of March, 1816), when he suddenly “sustained such exquisite torture from cramp in the stomach” (vol. iv, p. 37).

From the first attack, as given above, Scott had numerous ones during successive years. They were all characterized by similar symptoms: exquisite pain in the epigastrium, nausea and vomiting, jaundice, constipation, followed by soreness through the abdomen and back. Frequent references are contained in his letters to his more intimate friends during these years to attacks coming on usually after indulgence at the table, or during digestion, at periods varying somewhat from the beginning to the end of the process. Although hepatic calculi are not mentioned, and the attacks are always described as “cramp in the stomach” or colic, there can be no doubt these seizures were due to the passage of gallstones. The paroxysmal character of the attacks, the severe pain coming on suddenly, the nausea and vomiting, the rather sudden cessation of pain, the appearance of jaundice, and the considerable soreness and tenderness remaining afterward, make the diagnosis in a high degree probable. We hear of no attempts made to ascertain by a suitable examination of the stools the real cause. Nowadays, the physician would be singularly remiss who neglected to do this. To be successful the examination should be painstaking. The stools should be carefully stirred up in water, and every solid particle arrested for examination. A sieve sufficiently fine to stop any formation should be made use of; any solid obtained should be examined to determine whether a calculus or not. Mistakes are frequently made even now, and intestinal concretions, seeds, and olive-shaped fatty bodies are supposed to be calculi by those ignorant of their true shape and composition. In such a case as Scott, with numerous attacks, the calculi were no doubt of considerable size, angular, with smooth surfaces or facets, and composed for the most part of a nucleus of inspissated bile, surrounded by crystallized cholesterol. The occurrence of these attacks at some time during the process of digestion may be explained by attendant phenomena.

No doubt calculi are carried down into the cystic or common duct when the downrush of bile takes place on the entry of foods from the stomach into the duode-
Besides the enormous labor and the protracted sedentary life required to produce the immense result of his literary activity—the poems, the histories, essays, and novels—Scott in the midst of his unrivaled success began to experience some serious worry. Engaging in the publishing business with the Ballantines, and with Constable, who after a time failed most disastrous ly, and building the memorable pile of Abbotsford, he became seriously embarrassed notwithstanding that he was in receipt of enormous sums from his writings. He redoubled his exertions to retrieve his fortunes, and overwork was added to worry. He lost his wife when all of these pecuniary disasters were falling on him. His ambition to establish himself as a landed gentleman and "to found a family" seemed now to be impossible of fulfillment.

It is not often that work merely is a cause of disease; worry is a far more influential factor, and if we add worry to work, and to these free indulgence in the pleasures of the table and in drinking beer and wine and stronger liquors, we have the usual causes of the threatened or actual breakdown which so often happens to men at the middle period of life. When about fifty years of age, Scott began to suffer the muscular pains and joint changes of rheumatism. *Pari passu* we may suppose changes went on in the organs of circulation; the arterial tunies became the seat of atheroma, and the tension of the vascular system rose correspondingly. In his letters we find frequent references to "R.," which stands for rheumatism, and "R. R. for rheumatism redoubled," or for attacks increasingly severe, so that his hands were so disabled as to make his writing obscure and almost illegible. Attacks of rheumatism of the subacute and chronic type often precede serious cerebral mischief, coincident with more active alterations in the arteries and capillaries of the brain, and in the heart. No doubt the element of worry entered into the production of these results. Worry inhibits the cerebral functions, lessens oxidation generally and in the brain especially, and it favors the retention and deposit of waste products. Carlyle, as before mentioned, was greatly impressed with the changes wrought in his countenance by the terrible ordeal through which he was then passing. Instead of the round face, the brilliant eye, and the interesting expression of his "fine Scotch face," it was deeply lined, anxious, and wasted.

A considerable change in Scott's habits took place during the period of his calamity, and was a necessary consequence of the fallen state of his fortunes. As his literary labor had always proved so lucrative, he hoped, by devoting his whole time to his writings, to roll away the mountain of debt that had accumulated. To accomplish this object which lay so near his heart, he began to work double tides and labored unceasingly. His biographer says (vol. vii, p. 10): "Formerly, however great the quantity of work he put through his hands, his evenings were almost always reserved for the light reading of an elbow chair, or for the enjoyment of his family and friends. Now he seemed to grudge every minute that was not spent at his desk. The little that he read of new books . . . was done by snatches in the course of his meals."

As Lockhart well says, "Sir Walter was now to pay the penalty of his unparalleled toils," carried on as they were under the most imprudent, most exacting method of working. For some time he had experienced at irregular intervals attacks of headache and "nervous irritability," which alarmed him much. In letters to his publishers, he had several times alluded to his work as "smelling of apoplexy." Also he had other warnings of his impending fate, "harbingers," Lockhart called them. There was the more reason to be apprehensive in that heredity was well defined; both his father and elder brother having died of apoplexy.

The first distinct attack occurred in February, 1830, when he was fifty-nine years of age. He fell upon the floor, was unconscious, and speechless for ten minutes. The practice then pursued was quite effective; he was bled, cupped, and "tasted nothing but pulse and water for some weeks." Under this severe regime he apparently recovered—so nearly so that when he appeared abroad again, people generally saw no change, and he resumed work as usual. But a change had taken place: he was never again the same man, and the work he did bore evidence of failing powers. In commenting on this attack in his diary, he wrote as follows: "I was frightened by a species of fit I had in February which took from me my powers of speaking . . . It looked very palsy or apoplexy."

In explanation of this seizure, we may suppose that in consequence of chronic endarteritis, a capillary hemorrhage ensued, or a sudden thrombus formed in a small vessel, blocking it, and was followed by collateral hyperemia and edema. The method then employed to relieve was in the highest sense antithologistic, and certainly no plan of treatment could have been more effectual for the time being. Although the therapeutic diagnosis was based on the notions then prevalent, and would not be held now as worthy of consideration, in the light of modern pathology, the treatment is amply justified. To lessen the fullness and diminish the tension of the vascular system were clearly indicated at the onset of the cerebral mischief. Other attacks of a similar character occurred. The second seizure came on nine months after the first, and a third one year after the first; the fourth and final one, the immediate forerunner of his death, happened on the way home from his journey abroad. His mind failed progressively from the first in harmony with the decline in his bodily powers. All these were treated on a uniform plan. As soon as the symptoms of an attack came on he was bled freely, cups were applied, and his diet reduced to bread and water, or little more. Although this plan of medication was justified by the success achieved in the first
instance, yet with the progress of the case, the more frequent attacks, and the rapid decline in bodily strength, the lowering measures were carried too far. As there was found after death a considerable patch of softening in the left corpus striatum, the very severe antipillogistic measures carried out whenever a seizure was threatened or had occurred could only contribute to the extension of the pathological changes. It is stated in the autopsy that there was no alteration of the vessels, but the state of knowledge in those days was, as compared with now, primitive. Then nothing was known of cerebral localization, as now understood, and little of the minute anatomy of the brain. No doubt, if the vessels had been examined by the microscopical methods now employed, more or less advanced atheroma, especially of the vessels in the neighborhood of the softened tissues, would have been found. In cases of this kind, with rigid arteries at the wrist and temples, there is associated chronic endarteritis of the brain in those arteries most taxed in function, as the basilar, middle cerebral, etc.; but often the whole arterial distribution is more or less damaged with atheroma.

There was fluid in the ventricles and in the subarachnoid spaces—in other words, the brain was in the condition now known in the post-mortem room as the "wet brain." The report of the autopsy further states that there were three small "hydatid cysts" in the left chorioid plexus. There is no reason to suppose that these cysts were true hydatids, for there was no evidence of the presence of either echinococci or cysticerci. The right-sided paralysis was explained by the patch of softening in the left corpus striatum, but the language faculty was no more impaired than was the general intelligence. At no time did Scott have aphasia, for he was able to speak many words distinctly up to the last moments of his life. The softening did not enroach upon the paths of continuation of the motor neurons, coming down from the third left frontal convolution.

It is interesting to compare the therapeutical management of Scott's case with that which would now be considered as most appropriate. Assuming the existence of changes in the vessels of the brain, more especially the capillaries, with thrombi or emboli, extravasation of blood, and collateral hyperemia and edema, what measures of relief are indicated from the standpoint of existing knowledge? Bleeding is clearly useful when a hemorrhage is threatened, or, having begun in a small way, is proceeding with increasing momentum, or when the collateral hyperemia is augmenting, but only mischief is produced by repeated bleeding. When a large vessel has given way and the blood has broken through into the lateral ventricle no abstraction of blood can be of any service. When, as so often happens, capillary thromboses have formed, the question is, Can the permeability of the obstructed vessels be restored? There are two agencies which may be resorted to: alkalis to increase the power of the blood to dissolve fibrin, and cod-liver oil and the hypophosphites to improve the nutrition of nervous matter. The alkalis most useful under these circumstances are ammonia and the salts of sodium, notably the iodide. Our French colleagues have taught us the great value of sodium iodide persistently administered as a remedy for atheroma of the vessels, and for the abnormally high tension due to this state, as well as for the cardiac changes arising under the same conditions.

As in its ultimate constitution nervous matter is a phosphorized fat, to make use of the hypophosphites in conjunction with cod-liver oil is an eminently rational procedure. Here experience is in harmony with theory, but all active irritation must have subsided before they can properly be used. The same fact is true of strychnine, which is so much used to bring about the functional regeneration of the nerve structures. The time for its administration is when all local hyperemia has ceased and when the damaged structures have been repaired to the fullest extent they are capable of.

In further illustration of the remarkable changes that have taken place in pathology and therapeutics, it should be noted that nowhere is any reference made to the state of the renal functions. As the utmost candor in its revelations is characteristic of Lockhart's biography, it is not probable that any facts of this kind were withheld. The hepatic disturbances lasting over several years, and rheumatism, with its joint and circulatory changes, coming on subsequently, were circumstances extremely likely to bring about alterations in the renal structures. Chronic interstitial nephritis, with the presence of albumin and casts, would now be expected to play a part in the morbid developments of the case. It is probable that the melancholy decline in Scott's intellectual powers was in part due to defective renal action—to the complex of symptoms and structural alterations of uræmia.

1927 LOCUST STREET.

THE
PATHOLOGY AND THERAPY OF CANCER,
WITH SPECIAL REFERENCE TO
CANCER OF THE STOMACH.*

BY AUGUSTUS C. BERNAYS,
ST. LOUIS.

MR. PRESIDENT AND GENTLEMEN: You will allow me to thank you for the high honor which you have conferred on me on this occasion. While your selection has done me great honor, the choice of subjects which would be of interest to the members of this representative

* An address delivered before the Oregon State Medical Society at its annual meeting at Portland, June, 1899.
body of professional men is one which has caused me
some anxiety. After ripe deliberation I have come to
the conclusion that this is an opportunity for present-
ing the modern standpoint of a certain department of
medical science. I have been engaged in practical sur-
gical work for nearly twenty-five years as teacher and
operator, and shall base my critical remarks on the
advances that have been made in the treatment of can-
cer largely upon my own observations. There has been
great activity in the study of malignant neoplasms, and
the last few years have brought about a marked change
in the therapy of these diseases. We are now doing
operations of the greatest importance and extent and
are invading regions not thought of formerly. In fact,
these operations in cancer cases are of daily occurrence,
and are done by many surgeons in all parts of the world
as a matter of principle and of duty. In an address of
this kind it cannot be my object to present the results
of original research so much as to give you the pres-
ent views as they have been evolved by many laborers
in the laboratory and in the clinic. The main object
must be to arrive at some definite conclusions as to the
value of our methods of managing the very common
and apparently increasing numbers of cases of cancer
that seek our advice and our aid.

I shall use the word cancer in its general sense, in-
cluding the two forms of malignant neoplasms known
as carcinoma and sarcoma. I have a right to assume
that the histological structure of these growths is well
known to all of you as presented in the modern text-
books, and shall only call your attention to the fact that
there are forms of sarcoma which so closely resemble
some forms of carcinoma that a differential diagnosis
is not as simple as it might appear from the teach-
ings of the text-books. Some very important investi-
gations recently made seem to show that even epithelial
growth is preceded by changes in the connective tis-
sume which always underlies the epithelial layers of the
skin and mucous membrane. I have myself seen two
large-celled sarcomata which had a plain alveolar struc-
ture and puzzled all investigators very much indeed.
I wish to go on record as holding that the sharp line
which has been drawn between sarcoma and carcinoma
can not be maintained, and that in my opinion we are
far from an understanding of the biological signification
of the malignant tumors. The line of research which
promises to solve the question as to the origin of
tumors has been followed in a most laudable but as yet
only tentative way by that brilliant English surgeon,
Mr. Bland Sutton. His little work on tumors is so in-
stractive and so concisely written that I can not refrain
from recommending it to you, and promise you a rare
treat from its perusal. While speaking on the litera-
ture I can say that the work on tumors by my friend
Nicholas Senn, of Chicago, is the only work on the
subject written by an American surgeon which deserves
mention. It is a truly great book, and stands next in
importance to Senn's Principles of Surgery among the
works of that admirable and indefatigable surgeon.

I have just stated that a sharp line cannot be drawn
between sarcoma and carcinoma, and I must now tell
you that a line cannot be drawn which will everywhere
separate malignant from benign tumors. It is a fact
that the microscope alone can not be relied upon to make
a differential diagnosis between sarcoma and some forms
of granulomata. Sarcoma can not always be distin-
guished from lymphoma, nor from gumma, and not even
from some tubercular tumors, by any known his-
tological methods. The absence of tubercle bacilli in a
tumor does not prove that tubercle bacilli are not the
producers of the toxine which may have caused the
proliferation of cells in question. Even when to the
history and the microscopical examination of sections
of a tumor is added a full clinical examination by
means of all our modern methods, and by means of all
our instruments of precision, a reliable diagnosis is
sometimes impossible. Fortunately for us and for our
patients, these cases are extremely rare, but I felt con-
strained to bring out the existing defect in this address
because we are strongest when we best appreciate our
weaknesses.

Along the line of bacteriological research all at-
ttempts to solve the question as to the etiology of tumors
have not advanced our knowledge much. The numer-
ous alleged discoveries recently published still await
corroboration, and while, no doubt, some valuable facts
have been discovered, their authors have failed to prove
that the various parasites, some resembling amebae, oth-
ers belonging to the coccidium, and still others closely
resembling ordinary fungi of decomposition and sapro-
phytes, are really etiological or causative in the de-
velopment of cancer. These workers have, however, suc-
cceeded in proving to us that under the head of what we
call cancers, malignant neoplasms, some widely different
things are included. When we think of a malignant
papilloma or wart; of a small black sarcoma of the
chorioid, beautifully visible in the background of the
eye; of a soft, almost bloodless, white or gray sarcoma
of the fascia lata; again, of a hard scirrhous tumor of the
breast, or of a pulsating blue vascular sarcoma of the
orbit, we must all believe that under the head of cancer
are gathered a great many things which probably are
epletely widely different, and we all know that our
notion of malignancy is a most elastic one. We know
that some of these malignant growths are very slow in
doing their deadly work, while others kill almost like
acute infections caused by virulent poisons or toxines.

While I am reasonably certain from my own observa-
tions and experiments that some forms of cancer are
purely of extraneous or parasitie origin, I am convinced
that the great majority of tumors, benign as well as ma-
lignant, are developmental in their origin. It will be
shown that the large majority are referable to some an-
cestral inherited defect. The vast majority of tumors
BERNAYS: THE PATHOLOGY AND THERAPY OF CANCER.

will be found to be traceable to a rudiment of an organ which ages ago played a more or less important part in the physiology of our progenitors. Drawing the logical conclusion from the facts that have been proved about the descent of man from forms of life which in a long, unbroken line had been developed on this planet since it cooled off to such a degree as to permit of the exist-

ence of life as we know it, we can truly say that we have

almost infinite atavistic possibilities. Just as we now

positively know that a congenital fistula of the neck is a

remnant of a brachial cleft—of a gill, as it were—so will we some time in the future know how to explain the thousands of deformities and neoplasms, malignant as well as benign. The solution of the question as to the origin of tumors will come when the ontogeny and the phylogeny of the human animal shall have been worked out to a high degree by morphological, embryological, and biological researches. Much of this work I feel will be done on this side of the Atlantic by American students, in magnificent universities, richly equipped with all modern scientific apparatus in the finest laboratories on earth, endowed by the States and independent of the good will of the wealthy.

Before leaving the subject of the pathology and etiology of tumors, I must refer to the Cohnheim hypothesis, which attributes the origin of tumors to a matrix of embryonal cells which lie dormant in the form of cell lumps or misplaced islands of cells in the tissues. In order for them to develop, a suspension or diminution of physiological resistance in the tissues (whatever that may mean) must take place in the vicinity of the hypothetical matrix. In the absence of this "matrix of embryonal cells," the possibility of a tumor is absolutely precluded. I suppose the diminution of physiological resistance would be furnished by traumatisms, irritations, inflammations, adverse conditions of life, such as climate, poor environment, hereditary encumbrances, old age, etc.

If the existence of a matrix of misplaced embryonal cells is ever supported by scientific proof, it will be found in the form of "rests," "vestiges," or rudimentary organs. These have great significance when viewed from the developmental standpoint. Here, as elsewhere in the social and natural sciences, evolution will be the torchlight that will lead us out of darkness and ignorance into light and knowledge.

Let us now turn to the practical side of our subject and see what we can do in the way of treatment of malignant tumors. In the middle ages, when it was believed that an omniscient and watchful Deity distributed cancers among sinners as in his wisdom he saw fit to do, prayers were the logical remedy to be employed, and we have records of cures by this means. We also have certificates of cures of cancer by the more modern Christian Science, and the pamphlets sent out by the promoters of health resorts and of many natural springs contain plain statements of cases of cancer which were cured by the air and the waters of these springs. Se-

eral times in my life as a surgeon patients have come to my office bearing scars upon their bodies which they claimed were the scars of former cancers that had been cured by the waters of some springs or by the pastes of some quack. In every single instance a careful investig-

ation proved to me that the scars were those of syphilis or some more benign ulcer that had healed up rather in spite of than by virtue of the treatment they had undergone. The ignorant laity as well as designing fakirs are only too prone to call any chronic ulcer which does not yield to ordinary treatment a cancer. They do not know that the diagnosis of cancer is often very difficult and sometimes uncertain after all has been done that science offers. I have never seen a sponta-

neous cure of a cancer, nor have I ever seen one cured by medication of any kind whatsoever. The recently introduced methods of inoculation with crystales and other toxines, as well as the serum therapy of cancer, have now been amply tried and found wanting. I myself tried these methods in some cases which in my opinion were "inoperable," but could never record a permanent improvement, and, of course, a cure was out of the question. Where we find reports of favorable results of the inoculation treatment by good surgeons, we will usually find a statement that the pathologist found the tumor to be a spindle-cell or a small round-cell sarcoma. As above stated, the microscopic examination is not capable of positively recognizing or differentiating these forms of sarcoma from granulomata, or even from benign tumors which have their origin in the lymphatic or connective tissues. The pathologist was in error, and it is probable where a tumor recurs after an opera-

tion in or near the scar, and then disappears, that it is a granuloma, a keloid, or a benign fibrous or myxoma-

tous tumor, or perhaps simply a thickened cœliacal mass, such as we sometimes find in the subcutaneous tissues after operations. These growths sometimes require months and even years for their final absorption.

I do not wish to disparage the serum therapy or the inoculation therapy, and not even the injection of pyo-

tamin or alcohol or any other chemical into the sub-

stance of inoperable cancers. These methods, or new ones more or less like them, should all be tried before they are condemned. They are deserving of elaborate trial, as we can not predict their effects a priori; and in inoperable cases the attending surgeon must, at least for psychical effect, if for no other, do something to encourage the unfortunate patient in order to keep him from despondency or suicide.

I must insist, however, that in all operable cases the surgeon has no right to temporize or put off the opera-

tion for a period of more than four or six weeks, and even that short time may injure the chances of a suc-

cessful operative cure. Many of you will now ask, How can we draw the line between operable and inoperable cases? This, I will answer, is a purely relative matter,
BERNAYS: THE PATHOLOGY AND THERAPY OF CANCER.

[N. Y. Med. Jour.,

and what is inoperable for Dr. A. is operable in the opinion of Dr. B., and Dr. C. will perhaps consent to do the operation at once, and Dr. D. will even urge it and hold out good prospects of a successful operation, and, though a cure can never be promised, he will encourage the patient and inspire hope to such a degree that he will demand to be given the only chance of a cure which we have to offer.

The question as to the curability of cancer is finally and completely settled. Cancer, being a local disease in the beginning and spreading in the well-known way through the tissues by way of the lymphatics and the blood-vessels must be quite curable when it is possible to remove all the offshoots from the primary nodule. Clinical evidence and the observations of all surgeons who have been in the work for over fifteen years bear out this truth. Formerly, when cancer was regarded very generally as a constitutional affection, the operations were done with a view to merely prolong the patient's life for a short time, and a cure by operation alone was looked upon as hopeless. Thus the operator did his work in a half-hearted way, and, feeling that it could not achieve a complete cure, he did not feel justified in doing the extensive and formidable operations which we do nowadays. In the operation for the removal of the cancerous breast as it has been developed by Volkman, Billroth, von Bergmann, and Halsted, and as I do it in every instance, the wound is larger in area than the wound made for the excarication of the lower extremity at the hip. Some of our most careful and conscientious surgeons require as much as three or four or even five hours for the complete operation of a cancerous breast. In my opinion the surgeon must be prepared to do a complete operation, no matter how long it may take to do so, because upon the perfection and detail of the extirpation of all the diseased tissues depends the result. In one case I removed the breast, all the pectoralis major muscle, all of the minor, a good part of the fascia of the external intercostal muscles, all the contents of the axilla except the nerves and vessels, and the clavicle, together with a large bunch of supraclavicular glands and soft parts. The lady had had no return. The operation was done over six years and a half ago. In cases of cancer of the breast I have seen slightly more than half free from return three years after operation in something more than two hundred and fifty cases. In the last one hundred cases, done over three years, I have evidence of only twenty-one recurrences. I may as well say here that a recurrence must be treated in the same manner as the primary tumor, by immediate and radical extirpation, and, should there be a return, this must be attacked in the same way until the case is cured or becomes plainly inoperable by the involvement of inaccessible parts. There again I am reminded that what to one surgeon might appear inaccessible, to another might be perfectly within reach of the knife and scissors. Only he who has seen good results follow extensive and complete extirpation of whole regions of the body, large parts of the intestinal tract, etc., will have the inclination to do this line of work. Each surgeon soon learns the limitations of his skill, if he is convinced of the usefulness of extensive extirpations of cancerous growths. Every once in a while he will have a case wherein a patient dies of shock following one of his efforts to save a life. Deaths of this kind remind us of our limitations in such forcible and persistent manner that we are made to feel the responsibility of greatly endangering human life, even when that life is tainted by a destructive cancer. I remember at this moment some sleepless nights spent in going over and over in my restless brain the steps of a fatal operation, trying to find in what detail of the work I might have acted differently, perhaps better; how I might have saved the patient a few drops of the impoverished blood had I acted otherwise; how it might have been better if perhaps no morphia had been injected before the anesthetic was given. Thus a thousand more or less fantastic ideas rack one's brain, keeping away sleep, while the body is tossed from side to side until, the problem still unsolved, sleep finally comes to the relief of the exhausted organism. A few nights of this kind will dampen the ardor of even the most enthusiastic operator, and unless Nature has fitted him for the work by having given him strength and such nerves and organs of sense as will enable him to stand the ordeal of hard work in the daytime and a sleepless night now and then, he will abandon surgery and devote himself to some other line of work in the profession. There seems to be no danger then that surgeons will often go too far in their operations for the extirpation of cancers by the knife. Until recent years under the influence of antiseptic methods operations were entirely inadequate because they did not go far enough. But now we have arrived at a stage in surgery where we actually operate for the cure and not for the amelioration of cancer cases. Thus it will be seen that in recent years the object of operations for cancer has changed from a mere attempt at amelioration of suffering and prolongation of life to an attempt at a radical cure.

Let us now look at the limitations of the operative work. In examining a case of cancer the first question we must answer is whether or not there is any chance of curing the disease. The examiner will direct his attention to the lymphatics leading into and away from the diseased area with a view to detect any deposits or infiltrations in the same. He will also direct his attention to the lymphatic tissues some distance away from the cancerous growth, which may have become infected, though there be no visible or tangible change in them. Having determined these points, you can see that before beginning the operator knows what he will have to do. It will be his duty not only to remove all the plainly visible infected tissue, but also as much more of the sur-
rounding tissues as in his judgment may be the seat of microscopic nodules or cell nests. If the operator deliberately sets out to cure a case of cancer he will make up his mind to remove all of the diseased and suspicious tissues, and, as you can readily see, the operation will be a much more extensive procedure than was formerly undertaken. Just for example, I will mention two of the most important points. In a case of cancer of the breast, if the tumor has grown outwardly, so as to affect the skin, it will be necessary to remove a large area of it, because cancer is known to spread most rapidly in the subcutaneous lymphatic spaces. In a case of cancer of the tongue, or again of the breast, if the cancer has invaded one or more of the adjoining muscles, it will be necessary to remove all of the affected muscle from its insertion to its origin, and even the fascia surrounding the muscles must be entirely removed. The cancer cells are known to travel in the large lymphatics of the muscle and the perimysium with great case and rapidity; and if there is to be anything like certainty of cure these structures must be carefully and entirely removed. It is a good rule rather to remove more tissue than less, even at the risk of leaving impaired and crippled mobility of parts involved. You will judge from what has been said that an operation performed with a view of curing a patient of a cancer will become a much more serious one than the operation which simply aims at prolonging a patient's life by getting rid of the main trouble.

(To be concluded.)

HOME MODIFICATION OF COWS' MILK FOR INFANT FEEDING.

By HENRY DWIGHT CHAPIN, M.D.,
Professor of Diseases of Children
At the New York Post-graduate Medical School and Hospital.

Two things are desirable in the modification of cows' milk for infant feeding: First, a fairly accurate method of attaining the proper percentages of the various ingredients; second, a method of rendering these ingredients, as nearly as possible, in the same physical condition as they are found in woman's milk. Successful artificial feeding depends largely on the skillful combination of these methods so as to adapt them to each individual case. The preparation of an infant food must not be too complicated, and the ingredients and apparatus must be within the reach of all, under the ordinary conditions of life. Many good schemes fail because they are so difficult to apply. Percentage feeding certainly represents an advance, but it may be carried to a needless extreme. Complicated mathematical formulæ, even involving quadratics, have been devised, and expensive apparatus recommended to secure the needed percentages. The aim of the present paper is to procure a method that will be scientific enough for the average case and easy to apply in all cases. The first requisite is to consider cows' milk in the form in which it is everywhere procurable. There appears to be a fair grade of uniformity in the milk supplied by the better class of dealers. Government or municipal oversight, with a very close competition for the best trade, has compelled most dealers to exert great care in the production and handling of milk. An effort has been made by the writer to learn something of the actual conditions of the milk trade in Greater New York. There are in the boroughs of Manhattan, Bronx, and Brooklyn over fifty wholesale and retail milk dealers, whose capital ratings, according to the commercial agencies, range from $3,000 to $1,000,000. A list of questions was sent to these dealers asking, among other things, if they sold bottled milk to families and what percentage of butter fat they guaranteed. Nineteen replies were received, all from large dealers, their combined capital ratings being about two thirds of the entire capital invested in the milk business in these boroughs. These dealers guarantee their milk to run four per cent. fat and over, the least amount of fat being found in the spring months. A few of these dealers owned the cows producing the milk, but the great quantity of milk is collected by companies who have depots in various dairy districts and who buy from farmers and dairies. These companies have regular forms of contracts, which are generally based on the "Fifty Dairy Rules" of the United States Department of Agriculture. These contracts allow the companies' inspectors to examine the cows, stables, and utensils, regulate the manner of feeding, handling of milk, etc., and sometimes provide for notice to the company of any contagious disease in the family or help of the producer. The milk is brought to the depot at stated hours, morning and evening, cleaned if necessary, and immediately bottled and shipped either in boxes containing ice, or in refrigerator cars, and delivered within twenty-four to thirty-six hours after milking.

Milk should be aerated, strained, and cooled to 45° F. if for shipment, otherwise to 60° F., immediately after milking. Averating removes the gases which impart the cow odor to milk, and cooling to 45° F. prevents the development of lactic acid. The germs of lactic acid thrive at temperatures between 80° and 100° F., but are almost inactive at temperatures below 50° F. Milk bottled under these conditions and kept below 45° F. should keep in good condition for sixty hours after milking, as stated by Wing. Van Slyke, in a series of investigations extending over several years, and including the milk of not less than fifteen hundred different cows, found that as the percentage of fat increased, the percentage of casein increased in a nearly constant ratio; or, to quote his own words: "While we have noticed considerable variation when we consider individual herds, we have found that, as a rule, there were two thirds of one pound of casein for each pound of fat in
the milk, whether the milk contained three or four per cent. of fat, though this normal relation was considerably affected in the season of 1893 by the effects of drought upon the pastures. . . . When the amount of fat in the milk increased beyond four and a half per cent. there was a gradual but slight diminution of casein for each pound of fat.” (New York Agriculture Experiment Station, Bulletin 68, New Series.) It is thus evident that the casein bears a nearly constant ratio to the fat. The fat in the mixed milk of a herd of cows seldom falls below three per cent. or exceeds five and a half per cent. Probably four per cent. is a general average, and, as noted above, the majority of reputable milk dealers in this vicinity guarantee this amount. Fourteen quart bottles of milk from various dealers in New York and Brooklyn, bought at various times and assayed, showed an average of about four per cent. fat in the whole milk.

For over thirty years there has been in use in the dairy industry what is known as the “deep-setting” process of creaming. This process consists in putting milk into tall narrow vessels and cooling to about 40° F. After twelve to twenty-four hours practically all the fat of the milk will be found in the creamy layer. The skimmed milk often containing no more than a fifth of one per cent. fat. Milk bottled in the country and kept cool during the twenty-four to thirty-six hours before delivery is subjected to the conditions necessary for successful “deep-setting” creaming, and usually contains a layer of cream in the neck of a quart bottle between three and four inches deep, measuring from the top, or about six fluid ounces (Fig. 1). The position. Six samples were drawn with a pipette from the creamy layer of a quart of five-per-cent. milk, commencing at the upper surface of the cream, which tested twenty-eight per cent., twenty-four and a half per cent., twenty-one and a half per cent, sixteen and a half per cent., fifteen per cent., and eleven and a half per cent. fat. Slightly over six fluid ounces of cream were taken from this bottle, the average test being seventeen and a half per cent. fat. The remaining skimmed milk tested one and two fifth per cent. fat. That the “deep-setting” process of creaming applies to bottled milk, and that handling the bottle disturbs the cream very little, is shown by the following tests: A quart of bottled milk was bought from a well-known dealer. Six ounces of cream were removed and mixed, and two tests showed twenty-three per cent. fat in the cream. The twenty-five fluid ounces of skimmed milk were mixed and tested two fifths per cent. fat. A quart of milk was bought in the country, put in a quart milk bottle, and set on ice for twenty-four hours. Six fluid ounces of cream were removed, and two tests showed nineteen per cent. fat. The twenty-five fluid ounces skimmed milk tested three fifths per cent. fat. A quart of selected bottled milk, supposed to contain five per cent. fat, was carried on a journey of twenty miles on a train. Without allowing it to stand, seven fluid ounces of cream were removed, which, tested twice, showed eighteen and a half per cent. fat. The twenty-four and a sixth fluid ounces of skimmed milk tested one per cent. fat. It is evident, therefore, that a natural separation takes place in milk that is placed in bottles and preserved from fermentation for a certain length of time by being kept cool. This is exactly how most high-grade milk is served by the dealers. It must be cleansed, aerated, and carefully bottled in the country. Then when it is delivered to the consumer in twenty-four to thirty-six hours, the “deep-setting” process of creaming has practically taken place, and the different layers may be removed and mixed in any proportion, without further manipulation or separation. Unless the creamy layer is distinct when such milk is delivered, it is probable that bottling has not been done in the country, but in town. Not only is the proper creaming thus interfered with, but the chances of contamination increased. By thus mixing cream and skimmed milk, as it were in situ, in certain proportions, there is a certain relation between the fats and proteins that may be utilized in feeding the infant. In the home modification of milk by means of this bottled milk the cream is readily and accurately separated from the under milk by means of a dipper measuring exactly one fluid ounce (Fig. 2). Quart milk bottles all have substantially the same kind of neck, and the dipper has been made to easily fit into any of these bottles, after an inspection of a large number. The very top layer of cream is taken off with a teaspoon, and the dipper thus filled

![Figure 1](https://via.placeholder.com/150)

**Fig. 1.—Quart bottle of milk with dipper in situ.**

![Figure 2](https://via.placeholder.com/150)

**Fig. 2.—Dipper holding one ounce.**
and the first ounce removed, otherwise the milk would spill over when the dipper is let down. The successive ounces of cream are then easily removed without jarring, siphoning, or other manipulation. While it is not easy to test the proteins in milk, we are taught on good authority that they nearly equal the fat in milks up to four and a half per cent. fat. Avoiding small fractions, cream with twelve per cent. fat would have three times as much fat as proteins (twelve per cent. fat and four per cent. proteids); ten-per-cent. cream would have two times and a half as much fat as proteins (ten per cent. fat and four per cent. proteids); eight-per-cent. cream would have twice as much fat as proteids (eight per cent. fat and four per cent. proteids); six-per-cent. cream would have one time and a half as much fat as proteids (six per cent. fat and four per cent. proteids). Almost any desired percentage of fat or proteids can be procured by diluting these creams, using the cream that contains the desired ratio between fat and proteids. Having at hand a bottle of milk which has separated into two layers, one very rich in fat and the other very poor in fat, the problem of getting a cream of any desired percentage of fat consists in mixing the very rich milk with enough poor milk to reduce its percentage of fat to the point desired. In practice, creams containing twelve per cent. and eight per cent. fat are most useful. If it were possible to completely separate the fat from a quart of four-per-cent.-fat milk, nearly eleven fluid ounces of twelve-percent.-fat cream could be had, or sixteen fluid ounces of eight-per-cent.-fat cream. In the "deep-setting" process of creaming, about ten per cent. of the total fat is left in the skimmed milk, so we would naturally expect to get only nine tenths of the theoretical quantity of fat in the creamy layer. In practice, where it is desired to have fat three times the proteids, make a twelve-per-cent.-fat cream by taking the first nine dippers of cream and milk from a quart bottle on which the cream has risen, as shown in the illustration, and mix. Result, nine fluid ounces cream—about twelve per cent. fat, four per cent. proteids, five per cent. sugar. What is not needed of the nine fluid ounces can be put back into the bottle. For any quantity of food containing fat three times the proteids, use this formula with twelve-per-cent. cream.

Dilution of twelve-per-cent. cream = twelve per cent. divided by desired percentage of fat.

Fluid ounces-twelve-per-cent. cream = desired fluid ounces food divided by dilution.

Sugar = desired fluid ounces food divided by twenty.

Diluent = desired fluid ounces food minus fluid ounces twelve-per-cent. cream.

Example.—Desired twenty-four fluid ounces food containing fat, three per cent.; proteids, one per cent.; sugar, six per cent.

Twenty-four + three per cent. = four dilution.
and increasing the ease of assimilation. The curdling of milk by gastric juice or rennet must not be confused with the precipitation of casein by an acid. Rennet is a clotting enzyme which changes casein into a semi-fibrous mass that has a strong tendency to contract and harden, especially on the outside. Lactic acid accelerates the action of rennet, and the rapidity with which the curds contract and harden depends largely upon the quantity of lactic acid present. Rennet will not coagulate casein in the absence of the salts of lime. Milk that has been dialyzed to remove the salts or milk that has been boiled or Pasteurized will not coagulate well with rennet. In Pasteurizing or boiling milk, the albumin is coagulated and seems to envelope the lime salts, as the scum of boiled milk is rich in lime. After the addition of limewater and a little salt to dialyzed, Pasteurized, or boiled milk, rennet acts with great ease. Limewater contains about ten grains Ca(OH)_2 to the pint, so the beneficial results obtained by adding a small quantity of limewater to milk probably do not come so much from such a feeble effort at neutralizing the acidity of the milk as by allowing the rennet to act to better advantage. Plain gruels and milk, with rennet, form rather gelatinous curds. Upon dropping them into a solution of iodine and iodide of potassium they will at once be colored blue. After washing and breaking the curds it will be seen that the blue color does not extend into the curd, and that there is no yellow coloration, showing that the proteins are not exposed. In a gruel of the same strength, if the starch is dextrinized and mixed with milk and rennet, a curd will be formed that falls apart upon slight agitation. Drop some of this curd into the solution of iodine and iodide of potassium and it will be colored yellow, showing a larger surface of proteins exposed. The reason dextrinized gruel has such an effect on the curd is that, as the starch has largely been converted into soluble forms, the gruel is composed, in great extent, of the cell walls of the cereal from which it was made. This cellulosic is very flocculent, and when dispersed through the curd tends to prevent contraction and, as there is little adhesive material present, the curd breaks apart easily. This explains why the "flour ball" sometimes gives better results than a plain gruel, as the starch is more soluble than in plain gruels. It is thus an advantage to change the starch, which acts as a coating to the proteins in plain gruels, into dextrin, which is soluble, and thereby more freely expose the proteins to the action of the gastric juice. According to Schiff, dextrin provokes the secretion of pepsin, either when absorbed from the stomach or injected into the blood; hence this was a theoretical point in favor of dextrinized gruels. Pancreatic trypsin is totally inhibited by .05 per cent. of lactic acid, and as there is little ptyalin and trypsin secreted by suckling animals, the presence of fermenting starch may completely deprive digestion.

The older method of acting upon the starch of cereals by prolonged heating may be superseded by dextrinizing the gruel with diastase, which is rapid and simple. Most of the commercial malt extracts are sufficiently active in diastase to produce the desired effect. The writer, however, prefers the use of diastase itself, as being both speedy and efficient. It can either be produced cheaply at home or purchased at the nearest drug store. A simple decoction of diastase may be made as follows: A tablespoonful of malted barley grains, crushed, is put in a cup and enough cold water added to cover it, usually two tablespoonfuls, as the malt quickly absorbs some of the water. This is prepared in the evening and placed in the refrigerator overnight. In the morning the water, looking like thin tea, is removed by a spoon or strained off, and is ready for use. About a tablespoonful of this solution can be thus secured and is very active in diastase. It is sufficient to dextrinize a pint of gruel in ten or fifteen minutes. The following preparations are procurable if one does not care to prepare the diastase: Forbes's diastase, taka-diastase, Fairchild's pancreatic diastase, and an active glyc erite of diastase known as Cero, which is made for dextrinizing gruels.

NOTES ON

URETHRAL CATHETERISM, CATHETERS, AND BOUGIES.*

By J. W. S. GOULEY, M. D.

1. These annotations are intended as hints to physicians who have not yet become experts in the art of urethral catheterism,† and as warnings to auto-catheterists who have not acquired the skill and experience needed to cope with difficulties such as are often encountered in the use of bougies, sounds, and catheters. Under ordinary circumstances, few manipulations seem simpler and easier than the passage even of a rigid catheter to relieve a distended bladder. But let a wrong direction be given to the instrument's point, or be there some other obstacle to its progress bladderward, such as a stricture or an enlarged prostate, the

---

† Read before the New York County Medical Association, October 16, 1899.

‡ The inexact term catheterization is too often used by writers and teachers instead of catheterism, derived from the Greek καθαρασμός—a putting in of the catheter—which is Latinized into catheterismus, Gallicized into cathéterisme, and Anglicized into catheterism.
catheterist's tribulations begin. He is baffled, he loses self-control, his mind and hand wander, and he is obli-
gous to the relative anatomy of the urinary conduit and of the character of its texture, which, unfortunately for the patient, a high authority has advised him to "forget!" Before recovering from his mental con-
motion he makes a desperate, violent onward push that sends the catheter, perhaps an inch or two inches, into the ambient tissues, to the great distress of the sufferer, who, seeing blood issue instead of urine, frantically clamors for relief or pitifully groans from the pain inflicted, and is soon utterly demoralized. The picture just drawn is but a sketchy outline of what often occurs from unskilful catheterism. Urthral laceration, false routes, and other accidents are generally averted by observing the rules given, from the Celsian age to our time, for the performance of this delicate operation.

2. The term catheterism is used not only to convey the idea of putting in a hollow tool for the relief of a bladder full of urine, but for the introduction of instruments designed to explore or to irrigate the urethra and bladder, to crush vesical stones, to dilate the strictured urethra, or to remove foreign bodies.

3. For the sake of beginners, it may be well, before going further, to premise a short account of the history, nature, names, uses, and care of some of the instruments employed for catheterism. Of the history, young physi-
sicians need to learn enough to be cautious in their as-
sertions and in their claims to new inventions or modifi-
cations, and thus elude the literary fangs of the carping critic, or escape many acrimonious controversies. Of the nature, names, uses, and care of surgical instru-
ments, the knowledge of hospital interns is sadly defi-
cient, and ordinarily they care little for instruction in these particulars. The consequence is that ill-used in-
struments are soon cast away or relegated to the cutler, into whose hands they are too often delivered in a hope-
lessly damaged condition. Consistency in asepsis and success in treatment demand that the young physi-
cian shall know how to take proper care of his instru-
ments, besides understanding their principles of con-
struction and action, and being able to put together, for immediate use, those composed of several parts, and to dismount them for cleansing. Some surgical works in-
dicate the manner of accomplishing these purposes, but object lessons are indispensable. The interne should, therefore, frequently visit the surgical arsenal, examine the instruments with care, take them apart and re-
mount them, from time to time, until he shall have ac-
quired the needed knowledge.

4. It seems highly probable that tools for drawing off urine from the bladder were devised long before the solid dilators. In all likeliness the original catheters were straight reeds, curvature being the outcome of nature experience. The first authentic account of curved hollow cylinders was given by Celsus, who de-
scribed them as copper pipes of a length of fifteen fin-
gers' breadth, and gave directions for their use in rid-
ding the bladder of accumulated urine. Good exam-
pies of these curved metal tubes were unearthed from Pompeii.* The word catheter was employed by Hippocrates to signify any kind of tent for introduction into fistulous tracts following wounds, but the hollow cylinder for drawing urine from the bladder is not men-
tioned by that encyclopaedic writer; it was, however, Latinized by the Romans, and is used in some of their works to signify an instrument for drawing urine, named by them fistula, or syringa, a pipe. They used the word Specilum, which is equivalent to probe, for what in English is now named a sound, and catheter for the tubular instrument designed to empty the blad-
der. For probe the Spanish use the word tienta, from tentare, to search into. Catheter literally means a thing to let down or put in, from carâ, down, and levar, to send: or from calibras, to introduce, to send down. Sonda, sound, is from submunder, to submerge—sub, under, and undo, a wave. Alyorics and algories, used by the French and Spanish, are from the vulgar Latin argalio, from the vulgar Greek ἄργαλιον, which is derived from the classic Greek ἄργαλιος, meaning a tool, an instrument.

5. From what precedes it is evident that the terms sound, catheter, and algalia do not imply that the instru-
mements are solid, hollow, or even cylindrical, or that the catheter or algalia is intended to draw off any fluid; therefore, these arbitrary names are absolutely inexpressive, but, by general consent among English-
speaking people, are employed to signify the one a solid cylinder, and the other two hollow cylinders.

Aside from the inappropriateness of the names em-
ployed to designate these instruments, they are too often confounded, owing to a lack of general consensus among nations as to what should be the precise designation of each instrument. Solid metal cylinders are used to sound the bladder, but hollow cylinders are also used for the same purpose. A catheter, in the English sense, is often employed as a stone searcher, but a sound, in the same sense, can not be utilized in drawing off urine, since it is a solid cylinder. The instrument ordinarily called in English a sound is intended not only to sound the bladder, but to dilate the strictured urethra. As already noted, these terms are used in entirely different senses by several nations, notably the French, Italian, and Spanish, who call sonde, sonda, algalia, the instru-
mament named catheter by the German, English, and American nations. It is hoped that more distinctive

* A kind friend purchased, at Naples, and gave to the writer an excellent replica of one of the curved Pompeian copper or bronze cathe-
ters. It shows the sigmoid figure (adopted by Petit two centuries ago); the single eye appears to be rectangular, and is two millimetres in breadth, six millimetres in length, beginning at seven millimetres from the point, along the inner aspect of the curve and not on the side, as is the catheter eye of the present time; the vesical extremity, for a centi-
metre, is conical; the shaft is thirty centimeters in length, and the calibre six and a half millimetres—equal to No. 10 of the English scale.
and accurate names will eventually be given to these
tools, but the question of rightly naming them can only
be settled on a proper basis by duly delegated persons
representing the medical profession of the nations. For
the present, in English, let it be understood that cath-
eters is intended to designate an instrument for drawing
fluid from a cavity, and sound, an instrument for sound-
ing and for dilating.

6. Catheters and other tools designed for "putting into"
the urethra and bladder should be examined with
reference to the substances of which they are composed,
to their form, to their calibre, to their cavity, to their
apertures, to their curvature, to their length, to the
shape of their proximal and distal extremities, and to
their adaptation to the particular uses to which they
are destined. This study is of much importance in con-
sideration of the fact that catheterism is performed so
often and for so many purposes besides drawing off
urine.

7. The composition of catheters has a long and in-
teresting history, of which, however, a brief abstract
only is needed for the purposes of this note. It has
already been stated that tubes for drawing urine from
the bladder were originally non-metallic; that the pre-
cise time when metals, such as copper and bronze, were
employed in their construction is unknown, and that the
first written evidence of the use of metallic catheters is
from Celsus, but that they were in common use long
before his time. The metals long afterward employed
in the fabrication of catheters were lead, tin, silver, and
gold, and very recently German silver and aluminum
brass. The unthral fals routes so frequently made by
manufacturers catheterists with rigid metallic cylinders
induced surgeons to devise divers means to avert the
danger, without thinking that these accidents were owing
more to the performer than to the instrument. Lead
chageters were used in the nineteenth century by Rhazes on
account, as he believed, of their adaptability to such
forms as might be suggested by contortions of the dis-
cased urethra. Later, narrow bands of silver, twisted
spirally, were made into catheters. Of such material,
the spiral catheter of Solingen covered with leather
(1684) and the vermicular catheter of Roncalli (1741)
were made. From the times of Solingen and of Ron-
calli the same principle of action of these catheters has
been carried out by many surgeons, and nearly all spiral
or vermicular instruments have since been described as
new inventions. *

8. In the beginning of the eleventh century, Avi-
cenna used soft catheters made of the skins of animals,
coated with some sort of varnish to protect
them from the action of the urine. Fabrics of Aqua-
pendente was the inventor of horn catheters and of
others made of bands of linen coated with wax. Cathe-

* Several years ago Dr. Stuart Eldridge, of Yokohama, gave the
writer an admirably worked spiral catheter, made; it is supposed, by a
Japanese artisan—when, the donor could not ascertain.
the material for coating the braid, and in the manner of its application; in the method of polishing, and in the time consumed for the perfection of the instruments. The interior of the instrument should be as thoroughly coated and nearly as smooth as the exterior, otherwise it is soon fouled and infected with microorganisms. The best quality of silk should be used in the preparation of the cylinders and the braid should not be too close. The coating should be translucent and highly elastic, and should not be so thick as to render the braid invisible.

10. Great quantities of inferior catheters and bougies are still imported* and sold in different parts of this country. Their framework is of cotton coated with a varnish which hardens and soon becomes so brittle as to crack transversely all along the shaft, each crack being a fit lodging for colonies of bacteria besides being a point of election for fracture.

11. Trials made with divers kinds of flexible web catheters, treated with ordinary care, have given results worth recording. Lisle-thread and linen catheters, after being used fifteen or twenty times, often show many transverse cracks close together in a space extending four or five inches from the eye, and are thereby rendered unfit for further use; while in many instances good silk catheters used several times every day were free from cracks and in good condition after having

---

* It may be interesting to know how much the catheter industry has increased in this country, and to what extent importation has lessened in the past eight years. The following figures, obtained from one of the manufacturers, show the number of imported English, French, and German soft catheters and bougies in 1891 and 1898, and the number manufactured in the United States:

| Year | English | French | German | Total Imported | American | Indian

Thus, in the lapse of a few years, this industry has been developed to a degree which has already permitted in a year the exportation of one hundred thousand web catheters to England, Ireland, Scotland, France, Germany, Spain, South America, Australia, and India. There is also a large export trade in rubber catheters. These American catheters and bougies are fully equal to those manufactured in foreign countries, and some of them are even superior, notably the commercial and the best woven-eye silk catheters, as will be seen by a comparison of the tensile strength and of the quality of the varnish of the different instruments in use. The American (Tiemann's) India rubber catheters are superior to those of foreign importation in the construction of the eye, in the high polish of their surface, and in the smoothness of their interior.

been so used two hundred, and even three hundred times. Physicians will find it to their advantage to decline purchasing any but the best silk-web catheters, for, though their first cost is nearly double that of the others, they are so much more durable than the Lisle-thread or linen instruments that in the end they are the cheapest and least liable to break, while they can, without injury, be disinfected by means of formaldehyde vapor. It should be noted that nearly all these catheters harden when kept idle for a long time, and are to be cast away as soon as they lose their suppleness, for it is then that they are most likely to break during introduction or extraction. For use in warm climates a special coating is given to catheters and bougies, otherwise they stick firmly together and are thus spoiled unless dusted with talc.

12. The silk-web and the India-rubber catheters now replace very advantageously the metallic for drawing off urine, and few physicians think themselves warranted in using for that purpose instruments of metal or of any other rigid substance, except in certain conditions of the urethra requiring catheterism upon a conductor, or in cases of false routes relievable only by Mercier's invaginated catheter. The so-called silver prostatic catheter, with extraordinary curve and length, is a thing of the past which—with all due respect and veneration to Sir Benjamin—seems as if it had been intended for a urethral lacerator and prostatic plow, although, in good hands, it has often passed into the bladder without causing serious injury. The ordinary curved, elbowed, and double-elbowed web catheters, which average fourteen inches in length, answer well for drawing urine in cases of the very largest prostates, and the so-called prostatic web catheter of exaggerated curve is worse than useless. The writer has never seen a case requiring the use of this unsightly and unhandy instrument of torture. The catheter with funnel-shaped distal extremity for insertion of the irrigation nozzle is a superfluity on a par with the apertures for cat and kitten; only here the kittenish opening is the better, because safer. since, for obvious reasons, it is not wise to force a large and rapid stream into any bladder needing irrigation.

13. All sorts of fanciful catheters of silk, linen, ramie, or cotton web, or of caoutchouc, with wings or other projections near the vesical end, have been invented in the past thirty years, and soon rejected as worse than useless. One of these, in the writer's collection of confiscated catheteric curiosities, is of vulcanized grayish India rubber with a rich golden-yellow raw-silk thread wound spirally around the whole shaft—suggesting a fit habitat for millions of tiny organisms. The length of this extraordinary tool is fifteen inches and a half; its diameter corresponds to No. 10 of the English catheter scale; its countersunk eye is blind, for it had never been cut open, and it is probably the only specimen that had been made by the house of Tiemann.
& Co. Internal or external reinforcements for rubber catheters invite uneasiness. Those who invent such accessories do so with the idea of remedying the flimsiness of thin-walled catheters, which makes their introduction so difficult, whereas the desired object is so simply accomplished by giving each instrument sufficiently thick walls without much interference with the needed calibre of its lumen.

14. The properties of good web catheters may be stated as follows: 1. They are thoroughly, but not too thickly, coated with varnish inside as well as outside and highly polished; the varnish is pliable, not apt to crack, and resists the action of moist heat up to 212° F. (Early in 1839, the Ellwood Lee Company revived the translucent catheters, which about fifteen years before had a short vogue on account of their easily stripped thick coating of collodium. The new varnish used by the Lees in a comparatively thin layer is far superior and promises better results. It is, however, still on trial. Another elastic varnish, the “pegamoid,” of secret composition, has lately been suggested for coating catheters.) 2. In length they need not exceed thirty-three centimetres (about thirteen inches). 3. In diameter they vary from two to nine millimetres. 4. The distal extremity of their single oval eye is one centimetre from the point, which is smooth and rounded; this eye, in curved,* elbowed, and double-elbowed catheters, is generally lateral, but in some of these instruments the eye is superior, corresponding to the concavity of the bend, and in other cases the eye is omitted, the catheter being open at both ends, or, in addition to the eye, the vesical end is open for catheterism upon a whalebone conductor. 5. Good web catheters are firm but pliable, never rigid, from the proximal to the distal end; a web catheter with a rigid vesical extremity is a dangerous instrument, liable to cause false passages in the deeper regions of the urethra. 6. The form of the vesical extremity is in accord with its intended uses; straight web catheters are not so safely and easily used as the curved, elbowed, or double-elbowed, the curved form being the most easily introduced into strictured urethra and in the majority of cases of enlargement of the prostate. 7. The tensile strength of the different qualities of web catheters was ascertained by experiment to be as follows: That of an English commercial catheter was forty-two pounds, that of an American commercial catheter was fifty-four pounds, that of an American Lisle-thread catheter was fifty-six pounds, that of an American silk-linen catheter was sixty pounds, and that of an English silk-web catheter was eighty-five pounds. An American silk-web catheter of best quality was then tested to one hundred and fifteen pounds without breaking, but the varnish was stripped off at each end.

* Sir Everard Home was the first surgeon to suggest that the tissue of web catheters be braided upon a curved stylet, in order to obtain a curved instrument which will always maintain its curve.

15. When it is necessary to retain a catheter in the urethra and bladder, the physician should select one which has not been too thickly coated with varnish. The highest grade of catheter is not always the best for this purpose, because in the course of twenty-four hours the urine filters through the internal wall of the catheter, the silk webbing is saturated, swells irregularly, and uplifts here and there the coating of varnish, which soon scales off; while the Lisle-thread, silk-linen, and those silk catheters with thin external coating resist longer the action of the urine, and do not lose their smoothness after being retained forty-eight hours in the bladder. If, however, the interior of all web catheters were thoroughly varnished, and thus rendered impervious to moisture, there would be no irregular uplifting of the surface and no scaling.

16. The American commercial catheters have lately been much improved in quality, and they may be found very useful in hospital as well as in private practice. Their cost is little as compared to that of the higher grades. A catheter of this kind may be used for a single day and thrown away, or may be repeatedly boiled without injury, and used as long as the surface of the instrument retains its smoothness. These improved instruments are known as “ten-cent catheters.”

17. No catheter whose surface is fissured or otherwise roughened should be passed into the human urethra, because it would not only irritate this canal, but convey therein septic germs. For general use, physicians will find it advantageous to purchase the higher grades of web catheters, because, with proper care, they last long and retain their suppleness and smoothness. After having used an American silk-web catheter three hundred times, its surface was found to be as smooth as in the beginning. The instrument was then retired from active service to be preserved as an illustration of the excellence of home manufacture. Another American silk catheter was used twelve hundred times by a patient, and was set aside only because its surface had become irregular, although it was not cracked.

18. Web and rubber catheters are much injured by fats of all kinds, by glycerin, by saliva, and by vaseline, which, however, seems to be the least hurtful of these lubricants. If used at all, it should be in the smallest quantity—just enough to very thinly coat the catheter. Some physicians reject not only the fatty but all other lubricants, and think it sufficient to moisten the catheter with warm water. More soft catheters are destroyed by the excessive use of fatty substances than by any of the many other abuses to which they are subjected. Therefore there is need of a lubricant which shall not be irritating to the urethra, and which shall contain no fat and no free alkali to deteriorate the varnish of web catheters and soften rubber catheters. After examining different substances it was thought that a watery solution of dry soap, with the introduction of some ingredient to add lubricity to its viscidity, would
be likely to answer the purpose. Soap, deprived of glycerin and free alkali, is an efficient and unirritating lubricant, when mixed with a decoction of quillaja and duly sterilized. The following is a modification of the formula for a saponic lubricant, published in the New York Medical Journal, July 22, 1893:

Mode of preparation: Heat the soap and water, and stir until a homogeneous slime is formed; then add the three ounces of mucilage (made of the strength of one ounce of chondrus crispus to the pint of water). When cool, pour in the formalin, then the thymol and oil of thyme mixed with the alcohol; stir, strain, and keep in a covered vessel until all air bubbles have vanished. The result is an opalescent, slimy substance, of the consistency of honey, which should be put up at once in two-ounce collapsible tubes and sterilized. The chondrus crispus is substituted for the quillaja of the original formula because of the objectionable quantity of alcohol in the tincture, and because quillaja decoction imparts to the mixture a dirty pinkish tint, whereas the chondrus crispus mucilage is colorless. The Cetraria islandica was tested repeatedly and found unsuitable. The lubricant, in its present form, is sufficiently viscid, adheres well to the surface of all instruments, does not lump, and is unirritating to mucous membranes. The same quantity of chloral hydrate, or half the quantity of chloroform, or thirty grains of boric acid, may be used instead of the formalin, if desired, since it is intended solely as a preservative of the mucilage.

19. All web catheters should be kept at full length, and never coiled; otherwise the varnish will surely crack.

20. Web catheters should be loosely wrapped in dry antiseptic gauze, and preserved in tightly closed metal cases until wanted for use.

21. Before using a web catheter, it should be sterilized in formaldehyde vapor and be momentarily immersed in warm Thiersch solution to prevent cracking of the varnish, particularly during cold weather.

22. After using a web catheter, it should be well washed by forcing a stream of water through the instrument, which should then be dipped for a moment in Thiersch’s solution. It should then be thoroughly dried, wrapped in antiseptic gauze, and inclosed in a metal case. Catheters may be carried in hollow walking sticks, but never in the pockets of patients.

23. All web catheters are liable to harden, lose their suppleness, and be unfit for use in the course of a few years, especially when they have not been in use. On the first appearance of the hardening process, the instruments should be cast aside.

24. Soft India-rubber catheters should be kept at full length, never coiled, and should be wrapped in moist antiseptic gauze and preserved in tightly corked glass tubes, because exposure to the air leads to rapid oxidation, which causes the instruments to become hard and brittle.

25. Before using a rubber catheter, it should be sterilized in formaldehyde vapor and momentarily dipped in Thiersch solution warmed.

26. Rubber catheters become brittle in about two years, and sooner if unused and exposed to the air. But, when daily lubricated with fats, they seldom last more than three or four weeks, then swell, lengthen, and become so soft as to be liable to be torn across during withdrawal. Several inches of such deteriorated rubber thus often remain in the bladder.

27. When it is possible to teach a patient the use of the catheter, perhaps the safest instrument that may be placed in his hands is the “velvet-eyed” India-rubber catheter, which he must cleanse thoroughly before and after its employment.

28. Metallic catheters, with very few exceptions, should not be employed in attempts to relieve the distended bladder, because of their likelihood to damage the urethral canal and plow their way into the substance of the prostate, sometimes even when introduced with ordinary care. Being absolutely rigid, they can not readily follow the abnormal incurvations of the urethra common to multiform enlargement of the prostate. The so-called prostatic catheter is particularly dangerous, for it seldom reaches the bladder without detriment to the urethra, and too often finds lodgment in the recess of some false route, which, perhaps, it has made. When a false route renders impossible the passage of ordinary instruments, the contrivances known as Hey’s and Mercier’s modes of catheterism are generally successful, Hey’s method consists in passing, as far as, but not into, the mouth of the false route, a silk-web catheter, No. 9 or No. 10 (English), armed with a curved stylet, which is withdrawn with one hand at the same moment that the catheter is pushed toward the bladder with the other hand, when the instrument overrides the false route and enters the bladder. Mercier’s method consists in the use of two catheters, which together he has named the invaginated catheter.

29. India-rubber or caoutchouc catheters, known more than forty years ago, were little employed until the year 1873. The first were of pure caoutchouc and so flaccid that they easily collapsed. On this account vulcanization of the substance was resorted to in order to increase its firmness, but even then the catheters thus made gained little favor on account of their unpolished surface, their clumsiness, and their necessarily thick walls, which reduced the bore to a minimum. Sundry improvements in their construction were after-
ward made, and the first notice in this country of the improved catheters was given in 1873 by the late Dr. John D. Jackson, of Kentucky. These highly polished soft vulcanized caoutchouc instruments were styled Nelaton catheters and were made in Paris by Jaques. They were afterward further improved in New York and Boston. The attention of the manufacturers has been directed to several defects in the improved catheters. These defects are: 1. When the lumen is very large, it is at the expense of the walls; the instrument is then so flimsy as to be unfit for use. 2. When the walls are very thick, the lumen is too narrow. 3. When the oblong eye * is too broad and half an inch from the extremity, the instrument, during introduction, doubles upon itself at the middle of the eye, which is the weak point; this eye should therefore begin at about five millimetres from the extremity and be of the capacity of the lumen and no more. The lateral eye, however well made, being the point at which fracture is most common, may, with advantage, be omitted, and the instrument left open at the vesical extremity (such caoutchouc catheters with well-rounded ends were used for twenty years by a patient, who said that they never caused irritation and were of easy introduction). 4. When the vulcanized rubber used in the fabrication of catheters contains an excess of vulcanizing material, it soon hardens and becomes brittle, hence the frequent fracture of these instruments in the urethra or bladder; and when the materials are inferior or insufficient the catheters swell and lengthen greatly after being used for a short time.

* Multiple eyes in catheters of all kinds have long since been discarded for well-known reasons which need not be given here. Even two-eyed catheters are now among the curiosities of the surgical arsenal.

† Read before the Society of Alumni of Bellevue Hospital, May 3, 1899.

The story of the tragedy is not romantic and the actors in it were plain people. A farmer returning from a visit to a neighboring village found his wife lying dead upon the pantry floor, and near by the pistol with which she had been shot through the head. An inquest was held, a post-mortem examination of the body made, a verdict of suicide rendered; and until after her burial no doubt was expressed that she had died by her own hand. Nineteen days later, by the procurement of her family, the body was exhumed and subjected to reexamination. The husband was then formally accused of her murder. It seems to have been practically conceded that she was alone in the house from the time of his departure to the village till his return, an interval of less than three hours, and that her death occurred immediately prior to that departure by his act, or during that interval by her own. There was no contention that the crime, if such it were, might have been committed by a third person; the issue was clearly made between suicide and uxoricide, and had to be decided upon purely circumstantial evidence and upon expert medical testimony.

The motive for murder was asserted by the prosecution to have existed in the immoral relations maintained by the husband with a former servant in his household, both before and after her expulsion from the family. This intimacy had continued for many years and had led to a separation of husband and wife, followed by a reconciliation based upon his promise of reformation and fortified by a bond of indemnity, and was still existent at the time of the alleged crime. A quarrel with his paramour was assumed, rather than proved, to have been of such a nature as to become the immediate incitement to murder.

The motive for suicide was ascribed by the defense to a chronic ailment of the wife, and to the shame and infelicity of her domestic life, from which there seemed little prospect of relief.

The circumstantial evidence, while indirect and to the lay mind insufficient to convict, and to some extent discredited and contradicted, undeniably afforded strong ground for suspicion. The medical evidence by which it was supplemented was direct and unequivocal, and if accepted without reservation could leave no doubt of the prisoner's guilt. It was founded upon certain experimental observations by which the post-mortem appearances presented in the case in question were interpreted. These appearances, as noted at successive necropsies and attested at the trial, were sworn to be in the light of such experiments incompatible with a supposition of suicide, and, as the possibility of accident was not considered, were taken to afford absolute proof of homicide. The post-mortem conditions of the wound and of the head as described by the several examiners were undisputed.

(The Sheldon Murder Trial. A review of the medical evidence relating to pistol-shot wounds of the head. By Charles Phelps, M.D., Surgeon to Bellevue and St. Vincent's Hospitals. The recent sudden ending of a somewhat noted criminal case by the suicide of the accused person permits the publication of this review, written after a decision of the court of appeals had directed a retrial in the inferior court. The man had been convicted of murder and sentenced to death upon evidence founded in great part upon an observation of pistol shots made upon the cadaver, and upon the results of similar experiments in which various vegetable fabrics were substituted for the human tissues. This evidence challenges critical examination as to its pertinency and sufficiency, not only from its importance in this particular case, but, if accepted without question, in view of its effect as an established precedent.)
The body when first discovered was removed to a

**PHELPS: THE SHELDON MURDER TRIAL.**

The body when first discovered was removed to a
couch in an adjoining room, and after the arrival of
relatives, who had been summoned, was still warm. It
was superficially examined by the coroner from two to
two hours later, and was said by him to have been
then neither "cold nor warm," but whether or not
cadaverous rigidity had begun he was unable to state.
The head and both sides of the face were covered with
blood, which was still flowing from the mouth, nose,
and left ear. The bullet wound, round, clean cut, and
about the size of a lead pencil, was found just above
the tip of the right ear. There were no traces of
smoke about the wound, and no powder grains im-
bedded; there was no singed hair noted, no burn of
the epidermis, and no infiltration of gas. The right
orbital region was swollen and blackened, and the hair
was matted with blood. It was only after washing away
the blood that the wound and several powder stains
upon the tip of the right ear were discovered. Soap
and water were freely used about the wound and upon
the hair and left ear.

Two hours later necropsy was made by another
physician who testified to the following facts: Rigor
mortis incomplete; most of the natural heat of the
body dissipated; right upper eyelid discolored; face
clean; blood only in the left ear and in the hair of the
right side of the head; "lock of hair over the right ear,
covering an area as large as your thumb, which stood
out in a fluffy condition, not matted, very loose, ap-
peared to be singed"; a few of the hairs singed and
curled over were easily discernible; powder mark on tip,
and another, half an inch anterior, on rim, of the right
ear; another on the temple; "such as grains of powder
would make if they struck the skin when not ignited"
; witness thought there were other powder marks, but
could not swear positively; no grains imbedded; no in-
filtration of powder grains in the wound, and no pow-
der smoke on the right side of the head; bullet wound
not entirely round, elongated; subcutaneous tissues
about the wound "very much discolored, not torn, but
had more the appearance as though they had been
pounded" (confused?); and beneath the bone, "where
the bullet had entered the brain, parts were very much
congested"; brain very soft and pulpy; fracture in left
temporal bone just at left of orbit; bullet track through
the brain directed a little forward and downward.

At the conclusion of this examination the head and
hair were again thoroughly washed. The undertaker
who did this testified that he was fifteen minutes in
doing it, using three or four washbowls of water with
soap and sponge, and that he also washed the wound
with embalming fluid. A third washing of the head was
afterward made by the mother of the deceased.

Nineteen days after burial, the body was exhumed
and reexamination made of the wound and related parts
by a chemist and several physicians employed by the
prosecution. The observations made at that time were:

body and head in a fair state of preservation; grave
mold upon all parts exposed to view; slight odor of
decomposition; wound over right ear, formerly round,
and thirty-eight one-hundredths of an inch in diam-
eter; scalp not lacerated; hair dry, crimped, fluffy, and
evidently prepared for burial; hair burned at a spot
above, a little in front of, and contiguous to, the bullet
wound in an area of one fifth of a square inch, and
after discovery the burning readily visible to the naked
eye in a good light; a lock of hair, an inch and five
eighths in front of the wound, crimped as though pre-
viously heated and wound around some object; hair not
blown away from the wound; scalp and face clean, show-
ing no trace of powder or smoke; car clean, without
powder grains or stains, and having a black spot five
eighths of an inch wide upon its top with its centre
directly opposite the centre of the bullet wound; no
burning of the wound or skin; no imbedded powder
grains, and no deposit of gas or smoke in the wound;
no osseous entrance lead-stained and cut through by the
saw, leaving upper and lower segments perfect but
with edges fracted; skull thin, two sixty-fourths of
an inch in thickness at lower, and from three to five
sixty-fourths of an inch at upper and lateral margins
of the wound; bullet, which had passed through both
temporal bones, lodged at a point an inch and three
fourths in front of its point of entrance among lead-
stained osseous fragments; discoloration of right ocular
region. The brain, removed for examination at previ-
ous necropsies, had not been replaced. No deposit
upon trigger finger, but the number of washings to
which it had been subjected was unknown.

It was further stated by one of the physicians pre-
sent at this necropsy that the burning of the hair con-
tiguous to the wound extended downward closely to the
skinf and that the hair was burned off. It was also
learned from the same witness that a piece of bone,
approximately half an inch wide and an inch long, was
missing from the osseous wound; and that the spot upon
the left ear, which looked like a blood blister, occupied
the whole top of the rim.

Twenty days after the second necropsy examination
was made the body was again disinterred, and these
measurements were taken: Length of upper extremity
from the axilla to longest finger tip, twenty-eight inches
and a half; distance from shoulder to neck, seven inches
and three eighths; distance from neck to wound, five
inches and a half.

The last two measurements were made in lines inter-
secting in the neck at right angles.

Diameter of head—thickest part—five inches and
three quarters.

Upon this basis of facts, determined by necropsic ex-
amination, the contention of the prosecution that death
was homicidal, and of the defense that it was suicidal,
proceeded. Some effort made to establish inferences
from the observed phenomena of rigor mortis, and from
the retention of animal heat, elicited from the medical witnesses only discordant and unauthoritative opinions and was necessarily futile. The question of homicide or suicide was thus left to rest solely upon the interpretation of recognized surgical lesions of doubtful significance by a comparison with others experimentally produced under predetermined conditions.

The measurements which had been taken of the neck and upper extremity of the deceased were used to determine by a primary series of experiments the longest range at which a suicidal wound could be inflicted at the point through which she had been shot. These observations were made upon a living subject whose corresponding measurements were identical, and the distance was fixed at from six inches and a half to seven inches. This estimate, if not exact, may be assumed to be sufficiently so for the purpose of this inquiry.

The woman was killed with a five-chambered Colt revolver of 0.30 calibre, which, with the cartridge used, was purchased by the accused some twenty to twenty-five years before. This pistol, with cartridges of similar character and of the same manufacture, was employed in the experiments made at the instance of the prosecution. The shots, from four hundred and seventy-five to five hundred in number, were fired at ranges from contact to seven feet, at the human head and body, cardboard, wrapping paper, and wooden boxes. In this large number of observations not more than twenty wounds were inflicted upon the human subject, and of these, provided the ranges were short, the examinations exhaustive, and the results positive, not more than four could have been made upon each of the two heads which were alone available for experiment. It is positively stated that in the series of shots fired at the cadaver, but three were at contact. In every instance in which this particular pistol was used it was said there was a deposit upon the trigger finger, which was more pronounced when it was fired at the human body, and was denser in contact shots.

The leading witness who testified to the results obtained, and who had personally made the greater part of the experiments, was a chemist, who was generally corroborated as to facts and opinions by the physicians with whom he was associated. His observations of the effects of pistol shots upon the head of the cadaver at different ranges were:

At contact: Hole in the skull much larger than necessary for the ball to pass through; wound through the scalp much lacerated upon its edges and filled with powder smoke and grains; ring of heavy, dense powder smoke, from an inch to an inch and a quarter in diameter, surrounding the wound; hair blown about and radiating in every direction, "which is a characteristic feature"; skin immediately surrounding the wound more or less burned and, with the hair, thickly coated with a dense deposit of powder smoke.

At range of half an inch: Same subject; hair burned off and deposit of smoke in area of an inch and a half; hair violently blown away from the wound; hole through the scalp half an inch wide and three quarters of an inch long, irregular, and highly lacerated; tissues burned and filled with powder smoke and grains.

At range of five eighths of an inch: Same conditions, only more marked as to burning of the hair; beginning of slight deposit of smoke on tip of the ear.

At range of three quarters of an inch: Same conditions as regards point of entrance, except area of smoke deposit greater; hair burned in larger area; two thirds of ear densely covered with smoke; tissues lacerated and filled with fired powder in larger area; skin burned.

At range of an inch: Same conditions, except that area of smoke was about two inches in diameter; hair burned in same area; entire ear covered with smoke deposit; imbedded grains in area of a fourth of an inch.

At range of two inches: Imbedded grains in area of an inch; other features the same, only intensified.

Imbedded grains can not be washed out at any range.

At range of four inches: Hair burned to a crisp in area of an inch and a half; smoke stain in area of two inches, not removed by washing; imbedded grains, nearly whole, too numerous to count.

At range of six inches and a half: No singeing of hair; powder marks and grains in area of eight inches too numerous to count; top lobe of ear full of powder marks; grains imbedded whole; not removable by washing.

At range of twenty inches: Penetration of the skin with powder grains too numerous to count, covering an area of nine inches in diameter; did not rub off, and twenty grains could not be washed out. In a second experiment forty grains could not be washed out.

At range of twenty-four inches: Area of grains one foot; twelve large grains penetrated the skin and did not rub off; four could not be washed out. In a second shot at this range, seven grains were imbedded, leaving stains after rubbing off, and four left stains after washing.

At range of thirty inches: Grains too numerous to count, covered an area of one foot; not imbedded; left stains that would wash off but not rub off. In a second experiment the grains covered an area of eighteen inches; three were imbedded, and of these two would not wash off.

At range of thirty-six inches: Grains scattered over an area of one foot; four penetrated the outer skin, of which one, at a distance of three inches and a quarter from the wound, burned a hole; stains washed off. In a second experiment, the grains covered an area of fifteen inches and two were imbedded, one at a distance of two inches and a quarter from the wound; three stains would not wash off.

At range of forty-two inches: Area of grains one
foot; none imbedded; over twelve that would brush off; no stains. In a second experiment practically same results.

Experiments were made up to a range of seven feet. In all beyond six inches the wound was clean cut and round, and not infiltrated with gas or powder smoke. All the results detailed were obtained from the observation of shots made upon two subjects, and do not include any reference to subcutaneous or intracranial conditions.

The witness then summarized the results of the shots fired at the shorter ranges.

In every case from a range of four inches to five eighths of an inch inclusive: Hair burned to a crisp down to the scalp on every side of the wound in an area of from an inch and a half to two inches in diameter; hair blown violently away from the wound and densely covered with smoke; scalp lifted from the skull and a solid residue of powder grains and smoke beneath it; dense deposit of powder grains and smoke on the edges of the osseous wound, which could not be removed by washing. At all these ranges, except at five eighths of an inch, car black with deposit blown into the pores of the skin, as seen by magnifying glass after washing; hole through the tissues irregular and very large, giving no indication of the shape of the ball, and four to five times larger. When shots are fired at the angle of the shot in question, so that the space between the ball and the top of the ear is a twenty-fifth of an inch, the ear gives evidence that the ball has passed. This was noted from a three-fourth-inch shot and beyond. All shots made inside five eighths of an inch from the head left no mark on the top of the ear; but the conditions otherwise remained the same in every respect.

With the contact shot all the conditions were in evidence except the burning of the hair.

The witness further stated that he had burned hair at twenty-six inches with this same revolver and ammunition; that in one experiment in which hair half an inch in thickness was placed compactly the powder did not go through, and the bullet rebounded; that in another experiment in which hair was three quarters of an inch in thickness the grains burned through; that two particles of powder had burned twelve hairs at a distance of twenty-four inches; that the length of flame from this revolver was from less than twenty up to thirty inches; and that the projection of sparks was from five to seven feet.

He also exhibited wrapping-paper targets to show the conditions at different ranges, others of cardboard to show the greatest distance at which a grain of powder would ignite, and wooden boxes to show the size of bullet holes at various ranges and that powder grains would follow the bullet through the hole.

In his opinion the discoloration at the top of the ear, which showed unmistakable evidences of lead, was not a powder stain, but wholly blood and caused by a wound. He believed that particles of lead are scraped from the bullet in its passage through the pistol, which can escape only from its muzzle, proving that in this case the range of fire was more than five eighths of an inch. He also believed that live hair burns more readily than that which is dead; and that the soluble parts of powder will dissolve in the brain in ten minutes. These opinions were stated as facts.

Five physicians who had witnessed the experiments upon the cadaver, which have been detailed, confirmed the evidence given by their associate. They also testified that they had individually seen eight or nine cases in which a wound from a contact shot had been inflicted upon the living subject. Two of these gentlemen stated that there was less resistance offered by the living than by the dead skin to the penetration of powder grains.

Further testimony of an expert character was offered by a representative of the cartridge company manufacturing the cartridge which produced the fatal wound, as well as those used in the experiments. He testified that the cartridge with which the woman in question was shot was made between 1874 and 1878, and that those used in the experiments were made between 1878 and 1885, and that the effects would probably be the same; that the strength of powder is lessened by keeping, and that the change is due to chemical action and to the access of grease and moisture; that in old cartridges, as ascertained by experiment, particles of powder burn slower and carry farther, and their burning qualities are much greater than in those which are new; that in powder from twelve to nineteen years old there is a perceptible mark of burning at sixty inches, while with fresh powder there is scarcely a mark at forty inches, as determined by experiments with strawboard; that a difference in length of pistol, though slight, will affect the combustion of powder and its burning; that there are no exceptions to the rule as to the effects of burning powder at the distances named; and that with the pistol and cartridges used in the experiments, flame would project twenty inches and sparks five feet or more from the muzzle; and that the cartridge used in the case at issue was crimped tighter than those now made, which would cause a full or nearly full combustion of powder. He testified later, after having detailed experiments in which shots were made at blotting paper, that on firing at contact a blackening is invariably found on the first finger of the right hand between the first joint and the knuckle, more particularly with the pistol and cartridge of this case, as the cartridge is too short and allows the gas to escape; that in experiments, at contact and range of half an inch only, powder smoke, but no grain, was found in the rear of the muzzle of the pistol; that with this pistol and with old ammunition the bullet would have to travel from two to three feet before it would obtain its equilibrium; that at contact the bullet makes a larger hole than when fired from a greater distance in which
it has a chance to obtain its equilibrium; that it is
meant by loss of equilibrium that there is a second
explosion in the pistol of unconsumed powder as the
bullet leaves the muzzle and oxygen gets access which
gives the butt of the bullet a twist and causes it to
wobble, or sway to and fro; that there is always a
recoil at contact and powder is distributed to a greater
or less extent over the face of the target; that with this
pistol there would always be a quantity of unconsumed
powder grains; and that the hole is larger, and the
deposit much less, at contact than at a half an
inch. He had made no experiments upon the cadaver.

This hypothetical question, founded upon the medi-
cal and technical evidence adduced, was propounded by
the State:

"In the case of a person killed by a pistol shot of
0.30-calibre, the cartridge loaded with black powder,
the bullet entering the head just over the right ear,
with a hole the size of an ordinary lead pencil, clean
cut in the soft parts and small radiating fractures in the
bone, the soft parts being free from powder grains, not
lacerated nor infiltrated with gas or powder smoke or
deposit of powder grains or unburned powder in the
wound, no discoloration with powder smoke around the
wound or burning of the skin about the wound, or powder
grains in the flesh surrounding the wound or adja-
cent to the wound, five or six powder stains on the ear
and temple, what would you say as your opinion as to
whether this was a contact shot or not?"

To this question the physicians who had te-
tified as experts made negative answer.

The defense relied upon the evidence of but two
medical witnesses to oppose the experimental results
and to challenge the conclusions of the expert gentle-
men who had appeared for the prosecution. They had
made two hundred shots upon human skin, human hair,
blotting paper with and without a covering of hair, a
human head, and entire cadavers, using a Colt revolver
of 0.30 calibre similar in all respects to the one in the
hands of the prosecution, and with both old and new
cartridges similar in all respects to those used by their
opponents. They found no material difference in the
effects of the old and of the new ammunition. The re-
sults of their experiments made upon the cadaver were
described in detail."

1. At light contact: Through the hair; entrance
from an eighth to a quarter of an inch above the right
ear; hair slightly smoked and raised from side of head
in area not to exceed an inch; outline irregular and
difficult to measure; singeing did not extend down to
the scalp, and was easily removed by combing; none of
the hairs about the opening were singed; margin of the
wound burned: a little brain matter in the singed hair;
top of the ear slightly blackened from burned powder;
stain when removed with damp cloth still showed faint-
ly under the magnifying lens; skin of the ear unin-
jured; two small unimbedded grains of powder on the
right temple, and another one on the cheek a quarter
of an inch below the eye; scalp wound oval and slightly ir-
regular, but with no special laceration, measuring thirty-
two one-hundredths of an inch longitudinally by eight-
ceen one-hundredths transversely, and not admitting a
0.30-calibre bullet without pressure; slight blackening of
under surface of the skin; bullet passed through the
head, struck a table, and glanced across the room; exit
an inch in front of wound of entrance; no powder marks
between the skin and temporal muscle; soft parts about
the osseous entrance not detached more than an eighth
of an inch in any direction; no powder marks between
temporal muscle and skull, or in the osseous wound;
three small radiating osseous fissures, each three six-
teenth of an inch long; osseous wound nearly circular,
three-three to thirty-six one-hundredths of an inch in
diameter, and lead-stained only at one point; skull at
site of wound eleven sixty-fourths of an inch in maxi-
imum thickness: inner table more fractured than the
outer; no powder discoloration in the wound or brain;
three minute powder grains resting upon the edge of the
dura mater.

2. At contact: Through female hair applied to a
male head; entrance just above the right ear; singeing
of the hair in an oval area of an inch by an inch and
three fourths; no powder grains on the scalp; powder
smoke about the bullet aperture, readily removed by
washing; cutaneous wound nearly circular, with a lacer-
ation a fourth of an inch long in its lower portion; ear
blackened as in previous observation; this stain and
the singed hair removed by washing, leaving hair short
and stubby; blackness of the edge of the wound only
remained; some powder discoloration between the scalp
and temporal muscle; osseous wound nearly circular,
three-three one-hundredths of an inch in diameter.
and its edge lead-stained; tissues detached in area of
half an inch about it; small fragment detached from its
edge and held by the pericranium; substance of tem-
poral muscle pulp; dura mater and brain substance
slightly discolored by powder; bullet track through
brain bluish in color; skull fractured upon opposite side.

3. At range of five inches: Hair not singed or
burned; slightly stained by smoke and containing some
loose grains of powder; many imbedded grains in an
area of three inches, not removable by washing; cuta-
aneous wound thirteen one-hundredths of an inch in
diameter; no subcutaneous discoloration or laceration;
ossos wound nearly circular and thirty-five one-hun-
dredths of an inch in diameter; edge lead-stained; no
discoloration of brain.

4. At range of six feet: No singeing of hair or dis-
coloration; no imbedded grains; cutaneous wound
smaller than at five inches; osseous wound nearly cir-
cular, and thirty-five by thirty-seven one-hundredths
of an inch in diameter; bone and tissues stained only by
lead; brain not discolored.

The witness found it impossible to burn hair at a
greater distance than five inches, and did not believe that live hair burns easier than that which is dead. His associate corroborated this opinion and also testified that undecomposed dead skin, of the same texture as skin which is living, is of the same penetrability; that the skins of live persons differ in texture and thickness, and in different parts of the body; that the results of two contact shots are never just alike; that they differ in the amount and distribution of the powder smoke and grains and in the character of the osseous wound; that the same degree of contact can not be obtained in successive shots; that the quantity of hair is an element in determining the amount of powder which would reach the scalp; that powder will not dissolve in the brain, nor any part of it; and that human blood has a dissolving action upon powder patches.

The established fact that the subject which had been used for Experiment 1 by the defense had been injected with arsenite of sodium, starch, and red lead elicited some difference of opinion as to whether that treatment would affect the physical properties of the skin.

The results of experiments made with cardboard, blotting paper, and other substances, upon which both prosecution and defense seem to have in part founded their conclusions, need not be detailed, as in this review they will be regarded as irrelevant.

Some exhibits of portions of scalp and skull illustrating Experiment 1, and the skull used in Experiment 2, of the defense were submitted for examination to the leading expert witness called for the prosecution, who testified in rebuttal: that in the first he found fractures both on the outside and inside of the bone blown full of small particles of powder, detected only by microscopical and chemical examination; that in the scalp just above the bullet hole a lock of hair was singed for three inches in a length of six inches, and at the front of the scalp a small lock had been cut short with three hairs in it which had been singed; that the tissues surrounding the bullet hole had been burned and that in them there were products of burned powder; and that on the inside of the scalp about the wound there were minute patches of charcoal. In the second exhibit, the skull, he found powder deposits about the two osseous wounds made at contact.

The same exhibits were subsequently examined by a pathologist not otherwise connected with the case who testified that he had made microscopical examination of the piece of skull from the female cadaver (Experiment 1), of the skull of the male cadaver (Experiment 2), and of the piece of scalp; that in the hair were particles of carbon, but none of lead; that twenty singed hairs were burned close to the scalp; that he found neither black carbon particles nor lead around the osseous wounds upon the external osseous surface, but a small number of carbon particles and seven particles of lead around the wounds upon the inner sur-

face; and that in the skull in evidence particles of powder and of lead followed the bullet through the brain and were lodged in the opposite side of the skull.

Finally, it was testified that in some special experiments made by the medical witnesses for the defense, in which they fired the pistol used by the prosecution and charged with old cartridges, no trace of deposit could be discerned upon the trigger finger, either with or without the aid of the magnifying glass; and in proof of this, the finger of one of the two witnesses, which had been carefully protected from change, was exhibited, unsoiled, to the jury.

The hypothetical questions propounded by the defense differed from that of the prosecution only by one or two unimportant verbal changes and by the inclusion of singeing of the hair as a new condition.

This abstract of the testimony taken at a trial lasting over many weeks, though necessarily much extended, has been made as brief as is consistent with a proper presentation of all the facts and inferences which the medical evidence involved.

It is unfortunate, in view of subsequent action, that the early treatment of the body had not been more in accordance with medico-legal requirements. Its removal from place to place, and the repeated ablutions to which the head was subjected, could not fail to obscure or destroy important evidences of the etiological character of the wound. The interment of the body for a lengthened period prior to its final examination by the expert witnesses, who were to make its primary lesions and conditions the basis of inductive reasoning processes, was an additional element of uncertainty which has greatly weakened, if not wholly vitiated, their conclusions. The difficulties which attend a determination of the range at which a pistol-shot wound has been inflicted upon the living subject are under all circumstances much greater than when a similar wound has been experimentally made upon the cadaver. The flow of blood, which is often profuse, washes away the stains of smoke and powder, as well as the free and many of the imbedded grains; few cases escape some cleansing process and, unless death is immediate, some exploratory incision, before the opportunity for thorough examination is afforded. In this instance the repeated disturbances of the body, the unusually thorough washings of the wound, the apparently hasty and incomplete original post-mortem examination, and the combined influences of previous dissection and of lethal decomposition, must have changed, even to an unusual degree, the pathic conditions upon the study of which medical investigation of the manner of injury necessarily depended.

In every case in which the calibre, range, or direction of the bullet is brought in question certain characteristic alterations must be sought in the external soft parts, in the cranium, and in the cranial contents; and as they are present or absent, their positive or negative
diagnostic value must be fixed. These specific lesions which attend pistol-shot wounds of the head are, for the external soft parts: peculiarities of the cutaneous wound of entrance, burning of the hair or skin, staining of the skin by smoke, and deposit upon the surface or in the substance of the skin, or in the subcutaneous tissues, of unburned grains of powder or of the products of their imperfect combustion; for the cranium: the peculiarities of the osseous wounds of entrance and exit, the staining of the osseous surface, and the resulting fractures of the vault and base; and for the cranial contents: the staining of the dura mater and cerebral surface, or deposit upon them of powder grains, and the projection of powder grains and osseous fragments into the cerebral substance.

In this particular case the range of the bullet was the only fact to be established; its calibre was known by direct inspection, and its direction was obvious.

The range within which this woman herself could have inflicted the wound from which she died having been previously determined, there remained but a single question for solution: whether the distance traversed by the bullet was within the ascertainted limit of six inches and a half, within which either suicide or murder was possible; or whether the bullet was sped from a more distant point, and thus by necessity from the hand of an assassin. This question could be solved, in the absence of specific knowledge already acquired, only by a reproduction upon the cadaver, at a definite range, of the traumatic changes presented in the case at issue. It would be essential that such a result should be obtained under fairly comparable conditions. It must also be demonstrable by sufficiently ample experiment that this wound presented or lacked some feature which is invariably present or absent when inflicted within or beyond the established line of demarcation which separates possible suicide from unquestionable murder. The whole problem, stated comprehensively and in direct terms, would be to decide from adequate examination of the wound, aided by sufficiently well-considered and extended experiment, whether it had occasioned any change in the structure or appearance of the injured parts which is never observed as the result of a shot fired at a longer range than six inches and a half; whether it lacked any feature which is always observable when the shot has been fired within the same range; whether it possessed or lacked any invariable characteristic of wounds inflicted at a longer range than six inches and a half; and whether any real or apparent discrepancies in the answers to these queries which may exist are susceptible of explanation.

The positive alterations in structure and appearance of tissues which were observed in connection with this wound and upon which investigation was to proceed, as set forth by the several examiners, were but few: a spot upon the ear; a few powder stains upon the ear and temple; a little burning of the hair; a discol-oration and contusion of the subcutaneous tissues; an oval, clean-cut cutaneous wound thirty-eight one-hundredths of an inch in diameter; a circular osseous wound with a fragment attached to the perieranium; much laceration and softening of the brain, and a comminution of the opposite temporal bone, among the lead-stained fragments of which the bullet was lodged an inch and three quarters in front of its point of entrance. The absence of smoke stains, free or imbedded grains of powder, burning of the skin or wound, and of deposit of gas and smoke in the wound, were also noted as negative considerations of importance.

The experimental work which was specially undertaken both by the prosecution and the defense to determine the significance of these positive and negative indications was marked by great intelligence and care, but was vitally defective. In the greater part of the experiments made, cardboard, wrapping paper, or some other substance widely different in its physical properties from the tissues of the human body was employed; and in the smaller part remaining, in which use was made of the cadaver, but a small proportion involved the head.

A fundamental principle in generalization was thus ignored, since the conditions of experimentation were not even approximately comparable. It was properly stated by one of the witnesses for the defense that no two successive experiments can be made under precisely the same conditions, nor with precisely the same results. The range can not be made absolutely the same, and all cartridges can not be assumed to be exactly alike; atmospheric conditions differ; the skin varies in many particulars in different persons and in different parts of the same person; and other differences of circumstance are well-nigh endless. A very large number of observations, however, will show that such variations do not appreciably affect results, provided deductions made are not too rigidly construed. Conclusions are warranted only when sufficiently broad to include the varying effects of such comparatively trivial and unavoidable variations in the data upon which they are based. It is not justifiable, however, to so extend this latitude in the formation of opinion as to base it upon deductions from a comparison of radically different conditions. The effects of a pistol shot upon the human head can not legitimately be inferred from those produced upon a vegetable fabric. A multitude of observations upon targets of wrapping paper or of cardboard, or upon wooden boxes, though of unquestionable interest, and probably of great scientific value in other directions, can not illustrate the pathic changes which attend a bullet wound of the human tissues. Differences in humidity, inflammability, elasticity, and density are too great to permit a reconciliation of their results.

The number of observations made upon the cadaver was exceedingly small, and those upon the head, which were the only ones strictly relevant, were absurdly dis-
THE DIAGNOSIS OF TYPHOID FEVER.

A DISCUSSION

AT THE NEW YORK STATE MEDICAL ASSOCIATION,

OCTOBER 25, 1899.

BY WILLIAM OSLER, M.D.,

PROFESSOR OF MEDICINE, JOHNS HOPKINS UNIVERSITY, BALTIMORE.

"There is no one symptom, there are no two or three symptoms, which, in themselves, are characteristic of the disease. There is no one symptom, there are no two or three symptoms, usually occurring in the disease, which may not be absent during its entire progress. Our diagnosis can never be founded here, as it is in many other instances, on a few positive physical signs. It must always be rational, not absolute. The evidence, upon which our verdict is to be rendered, is wholly circumstantial. Notwithstanding all this, and although cases sometimes occur so enveloped in obscurity as to baffle the skill of the most careful and experienced observers, it is still true that there are few general diseases the diagnosis of which is so well established, and so certain, as that of typhoid fever."

These statements, taken from the remarkable work of Elisha Bartlett, On Typhoid and Typhus Fevers, 1842, express, with slight modifications, the position of the profession to-day on this all-important problem. I quote it designedly to emphasize at the outset the uncertainty which still besets us in dealing with some cases of this protean disease, notwithstanding the extraordinary advances in our clinical and bacteriological knowledge. In the time at my disposal it will be best to summarize the questions briefly in four divisions, which illustrate the conditions under which difficulty in diagnosis is experienced: First, variations in the intensity of the infection; second, the early and pronounced localization of the infection; third, peculiarities in the symptoms; and fourth, certain diseases which simulate typhoid.

I. VARIATIONS IN THE INTENSITY OF THE INFECTION. (a) The Mild Cases.—Every autumn we meet with cases of illness, from five to eight or ten days' duration, sometimes longer, in which, with gastro-intestinal disturbance, indicated by a furled tongue and diarrhoea, or quite as frequently constipation, there is a fever of slight grade. Perhaps on deep palpation the edge of the spleen may be felt. In such a case the appearance of a few rose spots may clear up the diagnosis, but in other instances the practitioner remains in doubt whether the condition is a simple continued fever or a mild typhoid infection. A relapse, with characteristic symptoms, or a well-defined post-typhoid lesion, may give the diagnosis; but most important of all is the presence or absence of the Widal reaction, which is nowhere of greater help than in this group. While it may not be present at first, even not until the fever has disappeared, it has been of very great service, and will be, I am sure, when more widely used, a special boon in these cases.

The method should be employed in widespread epidemics to help in the diagnosis of the milder forms. I may remind you of the exceedingly interesting account from Professor Sahli's clinic, at Bern, of the outbreak of typhoid fever in an asylum of the canton. In addition to thirty patients who had attacks severe enough to demand hospital treatment, there were twelve who had such slight symptoms as headache, fever, and diarrhoea, lasting only for a few days, and not severe enough to confine them to bed, yet the Widal reaction was characteristic. I am sure that a widespread application of the test will restrict within very narrow limits the cases of so-called simple continued fever.

(b) Acute Typhoid Septicaemia.—At the other extreme is the remarkable group in which the patients present the evidence of an acute infection of great proportionate to the comprehensive conclusions which, so far as they were justified at all, were founded upon them. It was declared without reservation, without the acknowledgment of the possibility of error, that the shot which killed could not have been fired at contact, and, as it would seem, it was left for inference that it was necessarily homicidal. This conclusion, which involved the life of the accused, was reached from the comparison of what was observed in connection with the wound which was to be accounted for, with the results of numerous experiments upon dissimilar objects, and the inspection of probably half a dozen wounds inflicted upon the heads of two cadavers.

It is remarkable that after exact measurements of the arm had been taken, necessitating much trouble and a special exhumation of the body, by which the extreme limit of range within which suicide was possible was ascertained, no use was made of the information acquired. The contention, as it was made, was not whether it was possible that the shot could have been fired within a range of six inches and a half, but whether it was or was not fired at contact. The hypothetical question proposed, by both the prosecution and the defense, and which may be supposed to summarize the medical case on either side, was confined to that single point. It would follow, though this question were conclusively settled, that the possibility of suicide was left still undetermined.

It seems to have been incidentally claimed by the prosecution that the shot was fired at a distance of from thirty to thirty-six inches, and though it may be improbable that in a section of the country in which shooting across the room is not much practised premeditated murder should have been committed at long range, its possibility requires consideration. The medical evidence, therefore, should be studied with reference to the effects of pistol shots fired not only at ranges of less than six inches and a half, but also at these longer distances.

(To be concluded.)
severity without any localizing symptoms. For a week or ten days the picture is that of a profound toxemia, with high fever and early delirium. Death may occur before it is possible to reach a diagnosis; even the Widal reaction may not be present. A post-mortem may show the characteristic enteric lesions, but not always, and the reports of Chiari, Flexner, Hodenpyl, and others have taught us to recognize typhoid fever without intestinal localization. There are cases in which a post-mortem diagnosis is negative, and only a bacteriological study may reveal the true nature of the disease.

II. EARLY AND PRONOUNCED LOCALIZATION OF THE INFECTION.—A majority of the cases of typhoid fever present no symptoms indicative of the special involvement of any organ or group of organs. A large proportion have no intestinal symptoms. Of thirty-five cases which have been under my care during the present month only four have had severe abdominal symptoms. The profession has had its attention too strongly directed to the enteric character of the disease; hence it not infrequently happens that we are completely taken off our guard when the brunt of a very acute infection falls upon some other system. Of these, the cerebro-spinal, the pulmonary, and the renal localizations are the most deceptive. Agonizing headache, severe neuralgia, delirium, or even furies mania may be the first symptoms of the disease. The so-called brain fever, the acute febrile mania, and cases with symptoms of cerebro-spinal meningitis are not infrequently typhoid fever, and it is important to remember that under the most favorable circumstances death may occur before a positive diagnosis is reached. A post-mortem may alone clear the obscurity, and in its absence the physician can scarcely be blamed when he returns the case to the health board under one of the above designations. Widespread bronchitis, acute pleurisy, with friction and subsequent effusion, early consolidation of a lobe of one lung may mask the true nature of the disease. The early renal localization is almost certainly called (as it is, of course) acute nephritis, of which there may be no single feature lacking, and the suggestion of typhoid fever may be delayed for ten days or more, when enteric symptoms appear, or the fever becomes more intense, or rose spots appear.

These clinical mistakes cause no little mortification to the young practitioner, who has not yet learned to dissociate his amour propre and infallibility in diagnosis. Even when hardened—humbled, I should say—by repeated exposure, it is not pleasant to be deceived, and a good rule is: When in doubt, keep your mouth shut. Unless one has a Cassioli-like volubility, in the flow of which the friends of the patient lose all idea of your true opinion, the gift of taciturnity should here be cultivated.

III. PECULIARITIES IN THE SYMPTOMS.—Elisha Bartlett's dictum, with which I began this paper, must ever be borne in mind. There may be no fever (though afebrile typhoid fever is very rare; I have never seen—to recognize—a case); the onset may be abrupt; there may be no rose spots, no intestinal symptoms; the diao reaction may be absent; the Widal test may be negative at the height of the disease; there may be hemo cytosis, and yet, as Bartlett says, "there are few general diseases the diagnosis of which is so well established and so certain." It is just in these negative cases, with fever alone, that the Widal reaction and the blood count may give us the only positive data, and the practical clinical value of the former, when carefully made, can not be overestimated, and it should be more widely used by practitioners. Wyatt Johnston's method (the dried blood drop) can be utilized, and there are now in almost every State laboratories in which the test can be made. Of positive symptoms which may lead to error I have time to mention only one—viz., chills. How often have I heard the protest, "But, doctor, the patient has had chills, repeated chills: surely he must have malaria"!

At the onset of the disease, at the onset of a relapse, as a result of treatment with antipyrine and antifebrin, at the onset of complications, in the typhoid septicaemia, and in the secondary infections of protracted cases and during convalescence, chills frequently occur. Most exceptionally they are due to malaria, which in reality is the last thing to be thought of (except in cases from the tropics), and the nature of which in any given case can be determined by the blood examination and by the therapeutic test."

IV. TYPHOID FEVER AND MALARIA.—I come now, Mr. President, to the only part of the subject worth discussing at the present moment,—namely, the diagnosis of typhoid fever from certain other diseases. To gain time I pass by acute tuberculosis, which trips us all at intervals (and I may say I am feeling sore from a fall over it not ten days ago), cerebro-spinal fever, meningitis, typhus, and the other acute infections, to take up the really serious question of the diagnosis of typhoid from the malarial fevers. During fifteen years' practice in the middle region of the Atlantic coast I have had only too forcibly impressed upon me the strange readiness with which physicians diagnosticate a continued fever as malaria. In this period I do not remember to have seen in consultation, in town or country, a single instance of continued fever, diagnosticated as malaria, which did not prove to be typhoid fever. I was fully aware, perhaps few men more so, of the widespread existence of the strong delusion on this subject in the minds of the profession, but neither I nor, I think, you who listen to me now were prepared for such a remarkable exhibition of its strength as that with which the late war presented us. The paper of Dr. Vaughan, based on material collected by the commission appointed by Surgeon-General Sternberg to study
the causes and spread of typhoid fever among the troops in the camps of the United States, has been characterized as an indictment of the general inefficiency of the men in charge of the camps. A demonstration on a wholesale scale was given of the ignorance in a large number of the members of our profession of essential elementary facts concerning these two diseases. While subscribing to the indictment, I feel that the gravity of the charge is less against the physicians than against those of us who occupy teaching positions. Who are the men responsible for this widespread error? Professor Dock, of Ann Arbor, who was on duty at the camp at Chickamauga, tells us in a few words. He says: "It is not necessary for me to defend the army medical service, for what struck me at the camps was the evidence of lack of knowledge of typhoid and malarial fevers in the profession at large. I came into contact with probably from sixty to seventy-five young physicians of a very good class, such as we would take into our hospitals as interns. Most of them, however, had no hospital experience, and very few seemed to have had any clinical experience with typhoid." The fault lies in reality with the system of teaching which permitted these young men to go out into practice without a thorough knowledge of typhoid fever. Here is the kernel of the whole matter. Looseess of diagnosis is inevitable while we send out the members of our graduating classes unfamiliar, by daily routine work in the hospital wards, with the clinical features of typhoid fever. But this is not the occasion on which to dwell further upon this point, while I bring it up only to place the responsibility for an acknowledged widespread ignorance where it should rest.

I have on a recent occasion, Mr. President, paid a tribute to the notable contributions on typhoid fever which have been made by three generations of American physicians. I am sorry that I can not speak in the same warm terms of the present generation in relation to the study of the modern problems of malarial fever. Fifteen years have passed since Dr. Sternberg's paper introduced to us in this country the brilliant work of Laveran, and in spite of the numerous confirmatory researches which have been made in Philadelphia, Baltimore, New York, and elsewhere, the enormous practical gain—namely, that we are everywhere able under all circumstances to determine the presence or absence of a malarial infection, has not been appreciated fully by the practitioner at large. One has to sympathize a bit with him—clinical fetiches are given up with difficulty and regret! To many good, easy men it came as a shock, to find that malaria was really a well-defined, easily recognizable disease. Naturally, it was hard to abandon a word like malaria, which carried with it as much clinical comfort as did that blessed word Mesopotamia spiritual atraction to the old lady. My sympathies have been deeply aroused by the distress which has been felt in many quarters of this city where you have been, until recently, with some notable exceptions, heretics of the worst kind. Nowhere, perhaps, has malaria ever covered such a multitude of diverse maladies. I came in contact with it first when in Montreal, a city in which malaria is unknown, so that when our patients returned from the hands of Gotham consultants with the diagnosis of malarial neurasthenia, or of latent malarial abscess of the liver, or of malarial headache of obscure origin, we learned to appreciate the mysteries of paludic infection as existing in the imagination of Manhattan practitioners. I have myself been scolded as too shockingly dogmatic on the subject, as some of you may remember, in a paper read a year or so ago by my friend, Dr. Beverley Robinson; but I protest that dogmatic as I have been, I have not been dogmatic enough. Had we teachers throughout the country been more persistently dogmatic, the profession might have been spared the mortifying exhibition of last year. But as for so many of us, so for Dr. Robinson, there is no possible salvation in this respect until born again of the microscope and a prolonged course of study of the genuine disease.

Two clinical rules should guide practitioners above Mason and Dixon's line:

1. An intermittent fever which resists quinine is not of malarial origin. Infection with the tertian organism, producing quotidian or tertian paroxysms, is the only variety of malarial fever prevalent in the Northern and Middle States. This form of the parasite is peculiarly susceptible to the action of quinine, and even a grain or two daily may suffice to clear the blood within forty-eight hours. The constancy, the infallibility of the action of this drug is one of the most remarkable phenomena in medicine. Our clinical charts of simple intermitents, now numbering many hundreds, may be searched through and through without finding an instance in which the paroxysms were not checked by the use of quinine, and usually within thirty-six or forty-eight hours.

2. In these localities a continued fever is not due to malarial infection. I am speaking now, remember, of the regions named, in which the astivo-autumnal organism and the graver forms of the disease caused by it are very rare. For remarkable complexity in the clinical manifestations, for variability in mode of onset, in the course, and in the symptoms, the astivo-autumnal infection takes precedence even of typhoid fever. With a vigilance quickened by repeated surprises, we are yearly made to feel the sublimity of this protozoan Proteus, which rivals "the old sea-tell-truth" of Homer's tale in clinical wiles and sleights.

So exceptional are cases of a continuous fever with tertian infection that they need not be considered, but the astivo-autumnal fever may simulate typhoid very closely. I shall not detain you with any detailed account of the differentia, which are fully described in recent works, but I may dwell on one or two points. The fever in malaria from the outset is marked by re-
missions—hence the term remittent fever—of a grade rarely seen in typhoid until the late stages. Once the fastigium is reached, the fever in the latter presents a remarkable steadiness; the two-hour record may show for several days a variation of not more than a degree. The chart has a "Pennsylvania-Railway-like" directness, in marked distinction to the zig-zag "Baltimore-and-Ohio-Railway" chart of astivo-autumnal fever. The early anemia, with sallow complexion, often suggests the diagnosis, even when other symptoms are like those of typhoid fever.

It is in these cases that we find the enormous diagnostic value of Laveran’s discovery. Unfortunately, the parasite of the astivo-autumnal fevers is less easily recognized in the acute stages than the larger tertian form, and, moreover, it may be very scanty in the circulating blood. To become an expert in the examination of the malarial parasites requires a long and tedious apprenticeship, and there have been illustrated papers published in this country which make one wonder not less at the brazen audacity of the authors than at the gross ignorance of the editors of the journals. I would urge most strongly, particularly upon the young house physician beginning the study, in all doubtful cases to keep well-made cover-slip preparations, which can be identified later by proper methods of staining. The recognition of an astivo-autumnal infection of a week or ten days’ duration is an easy matter from the presence of ovoids and crescents. Unlike the simple intermittents, the malarial continued fever is more resistant to quinine, and three or four days may elapse before the temperature falls, and the organisms do not disappear from the blood so promptly; indeed, the crescents and ovoids are remarkably resistant in comparison with the tertian form.

Combined infection with the typhoid and malarial germs is excessively rare; so rare, indeed, that only a single instance has been met with in the Johns Hopkins Hospital in ten years among nearly one thousand cases of typhoid fever. When it does occur, quinine readily settles the malarial side of the infection, while the typhoid fever pursues its usual course. It is to be hoped that the pernicious term typho-malarial fever has been forever banished from our nomenclature. Sheltered under it, a fancied sense of security has too often ended in a sad calamity, either to the patient or, in the absence of proper sanitary precautions, to the community.

But after all in any discussion on typhoid fever the appeal must be made to the hard-worked practitioners of the smaller towns and country districts (in which the disease is now most prevalent), who find it very hard, in the conditions of their lives, to take advantage of modern scientific methods of diagnosis. They must rely in great measure on experience and common sense, and to them I would say in conclusion—learn to suspect typhoid fever, and not malaria, in every case of fever of six or seven days’ duration, particularly if it resists the action of quinine. For too long have you employed the Anglo-Saxon method of procedure, and in a given case have assumed innocence of anything so serious as typhoid until in the onset of some serious symptom the guilt was only too evident! It is high time now that you adopt the Gallic usage, and regard every case of continued fever as guilty, that is as a typhoid, until the contrary be clearly demonstrated.

Two recent works should be on the library table of every physician at this season of the year—Keen’s Surgical Complications and Hare’s Medical Complications of Typhoid Fever. They will stimulate that personal progressive education which all of us should seek—an education which carries with it, year by year, as experience widens, not alone a better knowledge of the clinical intricacies, but an ever-ripening wisdom which enables us to be more and more helpful to the pitiable victims of this disgraceful disease.

**Therapeutical Notes.**

**An Ointment for Impetigo of the Head and Face in Infants.—**Kistler’s formula is thus given in the *Riforma medica* for August 12th:

- **R.** Salicylic acid ............... 2 parts;
- Bismuth subnitrate ............... 40 "
- Rose ointment ............... 100 "
- Powdered starch ............... 15 "
- M.

**For Flatulent Dyspepsia.—**Settimana medica for August 19th gives the following:

- **R.** Pure floride of ammonium .. 15 grains;
- Distilled water ............... 4,500 "
- M. A tablespoonful after every meal.

**A Mixture for Hemicrania.—**The *Riforma medica* for July 6th attributes the following formula to Leyden:

- **R.** Fluid extract of coca ............... 60 parts;
- Sodium bicarbonate ............... 5 "
- Sherry wine ..................... 20 "
- Melissa water ..................... 200 "
- Oleocasscharate of lemon ............... 10 "
- M. S.: A teaspoonful three times a day.

**A Powder for Gastric Acidity.**—The *Presse médicale* for September 21st attributes the following formula to Lemoine:

- **R.** Magnesia ..................... 4½ grains;
- Bismuth salicylate, 1 each ........ 7½ "
- Sodium bicarbonate, ..................... 5 "
- M. Five such powders to be taken daily, in a little warm Vietch water.

**A Lotion for Pruritus Ani.**—The *Riforma medica* for August 22nd gives Peuzoldt’s formula as follows:

- **R.** Sodium hyposulphite ............... 30 parts;
- Carbolic acid ............... 5 "
- Glyeerin ..................... 20 "
- Distilled water ............... 450 "
- M. To be applied on a compress.

A Weekly Review of Medicine.

Published by D. APPERTON AND COMPANY.

Edited by FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, NOVEMBER 4, 1899.

THE MEDICAL WITNESS.

It is an unwholesome spectacle that is too often spread before the public when any point of real or fancied importance in determining the result of a trial in court turns upon the medical testimony. Doctors differ ludicrously even as to matters of fact; when it comes to opinions, their differences are all the greater. All this is notoriously true, but we deny that it can correctly be held to imply that medical men are less learned in their calling, less truthful, or less logical than men of other professions. The physician who has had little or no experience in legal matters is apt to prove a bad witness. This we believe to be largely owing to the general lack of sufficient courage to say "I don't know." Most men who are supposed to be well informed in any branch of knowledge have a tendency to avoid admitting their ignorance as to any point connected with it. In the ease of physicians this tendency is nursed and developed by the course that they are forced to pursue almost daily; questions are asked of them in the everyday round of practice which they can not answer with positive knowledge, but to admit the lack of such knowledge would lower them in the estimation of the questioners, that is, their patrons. Consequently the practitioner of medicine falls easily into the habit of framing some answer which will "hold water" as things usually go, and he is apt to find himself unable to escape from the habit when he is on the witness stand. It is, of course, the lawyer's business to detect and expose the fallacies in ill-considered answers given by a witness, and if he chooses to dwell on them and magnify them testimony of great value in other respects is almost sure to be seriously impaired and the witness discredited.

But are medical men the only bad witnesses? We have an idea that lawyers themselves are not good witnesses as a rule; certain it is that they often fail to get what they are seeking for out of a medical witness, by reason of their ignorance or bad judgment. An example of this is given by Dr. David H. Stirling in an article entitled "The Unsatisfactory Conduct of Medical Legal Investigations, published in the October number of the Scottish Medical and Surgical Journal. "I once said to a counsel engaged in a trial of considerable importance to a railway company that he had quite failed to make the medical bearings of the ease clear to the jury," says Dr. Stirling. "His reply was 'Oh, it would have worried the judge!' It was quite evident that, however learned he might have been in law, he knew absolutely nothing of medicine and had not prepared himself to deal intelligently with the ease in hand." The "Yes or no; answer a direct question, please," adds Dr. Stirling, "is often the absurd demand of ignorance, still oftener the endeavor to turn aside a truth that damages the lawyer's ease." As a matter of fact, the preeminence of the doctor as a bad witness is rather a figure of the popular imagination than a point of serious belief with those who know; there are but few lawyers who entertain the notion carried beyond that of the doctor's notorious aversion to saying "I don't know."

Last week, at its annual meeting in New York, the New York State Medical Association made medical expert testimony one of its chief subjects of discussion. Judge Bartlett, of the appellate division of the supreme court, read an elaborate paper in which he dealt principally with proposed measures for remedying the present lack of confidence in such testimony. He thought that no change had any chance of being brought about which did not leave the expert witness subject to cross-examination, and this, as well as contradiction by "outside" experts, would have the effect, he said, of lessening the value of a system of official experts in the eyes of the jury. For our part, we quite agree with ex-Judge Daly that no effective substitute for the present system can be found, but that is not saying that the present system can not be improved. The improvement, however, must spring from the medical and legal professions themselves, and not from the legislature.

A MEDICAL VIEW OF GOETHE.

It is a never-failing source of gratification to reflect that so many of the great names of literature are those of men educated in medicine, if not practitioners of our art at some period of their lives. It is hardly less gratifying to recall that many other men whose writings will endure to the end of time were evidently deeply interested in medical science and, with scarcely an exception, felt respect and sympathy for the physicians of their times. It is always profitable to inquire into the attitude of a great man toward our profession. In our present issue Dr. Bartholow has a most interesting
article on The Medical History of Sir Walter Scott. In the Wiener klinische Rundschau for September 24th there is a notable article signed Paschkis which deals with Goethe from the medical point of view.

It is quite characteristic of Goethe, says the author, that it was immediately after reading Sömmering's Gefühlswerkezenge and Steffen's Grundzüge der philosophischen Naturwissenschaften, together with Montucslas Histoire des mathématiques, that he wrote his general review of Nature lore, explaining that it was the exalted views of these great men that had aroused in him the desire to place himself in the centre of the kingdom of Nature and Freedom. It is in the light of this lofty aspiration, Paschkis goes on to say, that we may comprehend Goethe's personal relations with the great physicians and other scientific men of his time, whose methods of thought and procedure he found very interesting.

We may judge of Goethe's regard for surgery, says Paschkis, from his calling it "that most godlike of pursuits." It was to surgery that, after many mistakes and wanderings, he brought his Wilhelm Meister, in whose life the surgeon's outfit played the part of an encouraging fetich up to the happy ending for him, for Natalie, and for Felix. That so majestic a career as Goethe's should have been to such a degree molded by his contemplation of medicine and the natural sciences, and his benign life so in sympathy with their devotees, we may justly look upon as a tribute of the first magnitude to their nobility.

SMALL-POX IN THE UNITED STATES.

It is now a number of years since there has been anything like a widespread epidemic of small-pox in the United States, and there is not now, in our opinion, a sufficient prevalence of the disease to give rise to alarm, but it certainly is prevalent enough, and has been for several months past, to emphasize the necessity of constant vigilance and the utmost energy in the work of vaccination. From June 30th to October 6th there were reported to the surgeon-general of the Marine-Hospital Service four cases from two localities in California (exclusive of the few that showed themselves in September among the men of a regiment of volunteers that had shortly before arrived from Louisville), four from three counties in Colorado, one from Connecticut, seventy-four from Jacksonville and seven counties in Florida (including fifty-three from the two counties of Gadsden and Hillsboro), forty from Savannah and two counties in Georgia, three from Chicago, two from two counties in Indiana, two from Kansas City, Kansas, a hundred and twenty-one from Louisville and Leslie County in Kentucky, seventeen from Louisiana (fourteen from New Orleans and three from Shreveport), thirty-two from two places in Maryland, twenty from five places in Massachusetts, an unstated number from Saginaw County, Michigan, nine from three places in Minnesota, twenty-two from two places in Mississippi, a hundred and thirty-nine from St. Louis and six counties in Missouri, six from Great Falls, Montana, sixty-eight from sixteen localities in North Carolina, forty from four cities in Ohio, six from Portland and an unstated number from Unamilla County, Oregon, two hundred and twenty-four from eleven localities in Pennsylvania (including sixty-four from Philadelphia), one from Memphis, Tennessee, a hundred and fifty-eight from twenty-five places in Texas, a hundred and twenty-one from eighteen places in Virginia, thirty-one from five places in Washington, and two from two places in West Virginia. In addition, six cases were reported from Ponce, Puerto Rico.

The assembling of a volunteer army is one of the favorite occasions for an extensive outbreak of small-pox, and our freedom from such an occurrence during the war with Spain was doubtless due to the fact that our recruits were not massed, but were quartered in small bodies at many distant points. Probably the Marine-Hospital Service has not received reports of all the cases that have occurred; indeed, there has been some prevalence of the disease in the western part of the State of New York, which does not figure at all in the surgeon-general's table, and ten or more cases were reported to the board of health of the city of New York during the period in question. Still, allowing for unreported cases, there has been no alarming prevalence of small-pox in the country. We repeat, however, that the number of cases has been large enough to call for unusual activity in the work of vaccination. While, as we have said, the assembling of an army is apt to be accompanied by an outbreak of the disease, military administration generally has the ultimate effect of bringing its prevalence below the ordinary rate in civil life. An irresistible example of this has been shown in Manila. The Lancet for October 7th says: "The argument upon which the antivaccinationists chiefly rely is that the wonderful decrease in small-pox is not due to vaccination but to improved sanitation. A letter recently received from a surgeon of the Thirteenth Minnesota Volunteers, now in Manila, notoriously one of the most insanitary towns in the world, affords further proof of the fallacy of this reasoning, and, at the same
time, once again demonstrates the efficacy of vaccination. Dr. Ritchie, the surgeon in question, says: "April and May are the small-pox months in Manila. Two hundred and fifty deaths a month was not considered an excessive number nor esteemed an epidemic. Since our occupation no such number has occurred, and owing to the untiring efforts of Major Bourne, health inspector of the city, the mortality is almost nil. Over fifty thousand persons have been vaccinated, and the good work goes on. . . . Our vaccine is now almost entirely used, with the effect that the disease is not only under control but almost "stamped out." The foregoing statement is most valuable testimony in favor of vaccination. The sanitary conditions in Manila were as defective as possible, and yet vaccination alone was sufficient to abolish small-pox."

EXONERATION, BUT NO AMENDS.

The recent outrageous arrest of two reputable physicians because they were the last, except those of Bellevue Hospital, in attendance on a woman suffering from the consequences of an illegal operation has been followed by their honorable discharge after several days of worry and inconvenience. It seems to be the general impression that they owed their discharge to the fact that they did not know the nature of the woman's trouble, but we take it that Coroner Fitzpatrick entertained a broader view of the matter, for he is reported to have looked astonished, as well he might, when informed of the cause of their arrest. It is a pity that it was not in his power to cause amends to be made to them for the indignity put upon them, and it is still more a pity that medical attendance on a woman who has submitted to an operation to bring on abortion should be considered as in the least deserving of reproof. Physicians do not feel the I-am-holier-than-thou sentiment that would make the rendering of assistance to a sufferer conditional on the patient's being able to show a clean bill of moral health.

KOPILIK'S SIGN IN THE EARLY DIAGNOSIS OF MEASLES.

Verily there is nothing new under the sun. Dr. Siegfried Weiss, of the Carolina Children's Hospital, Vienna, has written a letter to the editor of the Medical Record, published in that journal for October 21st, in which he shows that the preexanthematosus lesions observable in the mouth were accurately described in 1880 by Dr. Flinelt, a Danish physician, and that his description was "exhumed out of the records of the Danish Sundhedscollegium" by Jürgensen and published in Nöthnagel's Pathologie und Therapie. None the less credit, however, is due Dr. Koplik for having called attention to the sign, which no doubt he discovered independently.

"BLOOD IS THICKER THAN WATER."

Whatever may be an American's sentiments concerning the war between the British and the Boers, he can have but one feeling, that of gratification, we take it, over an enterprise undertaken by a number of women of American birth living in England as a recognition that "the people of Great Britain by their sympathy and moral support materially aided the people of the United States in the war in Cuba and the Philippines." Their plan is to raise a fund from their fellow-Americans for the relief of the sick and wounded soldiers and refugees in southern Africa, and to equip a hospital ship with accommodations for two hundred patients. The committee formed to carry out this gracious purpose consists, we understand, of Lady Randolph Churchill (formerly Miss Jerome), the Duchess of Marlborough (formerly Miss Vanderbilt), the Countess of Essex (formerly Miss Grant), Mrs. Joseph Chamberlain (formerly Miss Endicotl), Mrs. Arthur Paget (formerly Miss Stevens), and Mrs. Bradley Martin. Their good work is in every way worthy of encouragement.

"A LITTLE POCKET FOR FEES AND A BIG POCKET FOR INSULTS."

Seldom has this old saw proved more strikingly applicable than in the case of Dr. Lamont, a parish physician of the western coast of Scotland, described in a London letter printed in the Medical News for October 21st. There was an endemic of typhoid fever in the parish, and the community became so panic-stricken that in many instances nobody but Dr. Lamont could be induced to go near the sufferers in their last days, so that he had to act as physician, nurse, and undertaker. In his rôle of unassisted undertaker he was obliged to resort to crude methods which called down upon him the public accusation of having maltreated the dead—this, however, not until after he had been cleared of a flimsy charge of having improperly issued vaccination certificates, kept in jail for two or three days, and dismissed from his office in disgrace. All these indignities were heaped upon him at the instance of the parish council, but by parliamentary intervention his wrongs were finally righted so far as possible. It is to be feared that he still has to live among the barbarous people of the parish.

APPENDICULAR TROUBLE AND THE SARTORIUS.

Among the recent gems of newspaper medicine is an article reproduced in the Sun from the Glasgow Mail, in which "a well-known medical man" is said to have "announced," among other things, that the reason for the greater frequency of appendicular inflammation in the male sex was their habit of sitting with the legs crossed. It might be well to ascertain the relative frequency of the disease among tailors and among other men.

AN INCREASE OF HERNIA IN THE AUSTRIAN ARMY.

Armies are incidentally useful for other purposes than those of warfare; large collections of men living under practically uniform conditions, well fed and well cared for as to their health, furnish an excellent field for observation in physiology and pathology. Mandl (Militärarzt, 1899, No. 9; Fortschritte der Medicin, September 27th) reports a steady increase of hernia in the Austrian army for a number of years past, and he finds it difficult to account for the fact. It would be interesting to know if there is a corresponding increase of hernia among the civil population of Austria.
REMOVAL OF THE STOMACH WITH INTESTINAL RESECTION.

Not to be outdone by those who have simply removed the entire stomach, Kocher (Deutsche medizinische Wochenschrift, September 11th; Klinisch-therapeutische Wochenschrift, October 1st) has performed that operation and at the same time resected a portion of the transverse colon. The patient died on the fifth day afterward, but the post-mortem examination showed that there was no reason why so extensive an operation should necessarily fail.

THE TEMPERATURE OF THE AGED.

The sensitiveness to cold shown by persons of advanced years is a matter of common observation. It may be dependent on arteriosclerosis, to which Chelmanski (cited in the Wiener klinische Rundschau for September 3rd) attributes certain abnormalities of temperature that he has observed in old persons. He reports 1,682 observations made on 111 individuals over fifty years old between the hours 8 and 10 a.m. and 5 and 7 p.m. He finds the temperature frequently lower than normal, and not uncommonly an inverted type, the temperature being higher in the morning than in the evening. The sclerosis is said to act by crippling the contractile power of the great vessels.

THE "TRIGGER FINGER" AND THE QUESTION OF MURDER OR SUICIDE.

In the Sheldon murder trial, as related by Dr. Phelps in this issue of the Journal, much attention seems to have been paid to the question of whether or not the deceased’s "trigger finger" was powder-stained, but it does not seem to have occurred to anybody connected with the trial that in such a case of suicide it would be more natural for the person to pull the trigger with the thumb than to give the wrist the awkward strain required for pulling it with a finger, and that the use of the thumb would increase the possible length of range.

ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported for the two weeks ending October 28, 1899:

The New York Obstetrical Society.—At the annual meeting, held on October 10th, the following officers were elected for the ensuing year: Dr. Clement Cleveland, president, Dr. H. J. Boldt and Dr. R. Waldo, vice-presidents, Dr. R. L. Dickinson, recording secretary.

Dr. E. A. Tucker, assistant secretary; Dr. E. E. Tull, corresponding secretary; Dr. J. Lee Morrill, treasurer.

Marine-Hospital Service Health Reports.—The following cases of small-pox, yellow fever, cholera, and plague were reported to the surgeon-general during the week ending October 27, 1899:

**Small-pox—United States.**
- Butler, Mass. . Sept. 30-Oct. 18 . 2 cases . 1 death.
- Butte, Mont. . Sept. 20-Oct. 18 . 2 cases . 1 death.

**Small-pox—Foreign.**
- Prague, Austria . Sept. 23-Oct. 7 . 5 cases .
- Antwerp, Belgium . Sept. 25-Oct. 16 . 4 . 4 deaths.
- Athens, Greece . Sept. 5-Oct. 7 . 8 . 3 .
- Madras, India . Sept. 16-22 . 1 case . 1 death.
- Moscow, Russia . Sept. 22 . 1 case . 1 .
- Odessa, Russia . Sept. 8-Oct. 7 . 7 cases . 2 deaths.
- St. Petersburg, Russia . Sept. 23-30 . 3 . 1 death.
- Warsaw, Russia . Sept. 23-30 . 5 deaths.

**Yellow Fever—United States.**
- Key West, Fla. . Oct. 16-22 . 61 cases . 4 deaths.
- 2 .

**Yellow Fever—Foreign.**
- Rio de Janeiro, Brazil . Aug. 11-25 . 3 cases . 6 deaths.
- Havana, Cuba . Oct. 5-17 . 15 .
- Santiago, Cuba . Sept. 23-30 . 1 death.
- Tampico, Mexico . Sept. 22-29 . 2 cases . 1 .
- Tuxpan, Mexico . Oct. 2-16 . 15 deaths.
- Vera Cruz, Mexico . Oct. 12-19 .
- Santa Cruz, Teneriffe . Sept. 16-25 . 2 .
- Erzeroum, Turkey . Sept. 17-23 .

**Cholera.**
- Calcutta, India . Sept. 8-16 . 2 deaths.

**Plague.**
- Bombay, India . Sept. 19-26 . 82 deaths.
- Calcutta, India . Sept. 8-16 .
- Kurrachee, India . Sept. 16-23 . 4 .
- Tamatawe, Madagascar . Sept. 8-16 . 2 cases . 2 .

Alvarenga Prize of the College of Physicians of Philadelphia.—We are informed that the College of Physicians of Philadelphia announces the next award of the Alvarenga prize, derived from the income for one year of the bequest of the late Señor Alvarenga, and amounting to about one hundred and eighty dollars, for July 14, 1900, provided that an essay deemed by the committee of award to be worthy of the prize shall have been offered. Essays intended for competition may be upon any subject in medicine, but must not have been published, and must be received by the secretary of the college on or before May 1, 1900. Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within
the name and address of the author. It is a condition of competition that the successful essay or a copy of it shall remain in possession of the college; other essays will be returned upon application within three months after the award.

The Alvarenga prize for 1899 has been awarded to Dr. Robert L. Randolph, of Baltimore, Maryland, for his essay entitled The Regeneration of the Crystalline Lens—An Experimental Study.

A New Convalescent Hospital for United States Soldiers is, according to the Army and Navy Journal for October 11th, being built on the island of Corregidor at a cost of sixty-four thousand dollars. It is on a plateau facing the bay. The building is being constructed of wood, with iron roofs, and being raised a number of feet above the ground. The main building consists of three large, airy wards, with an isolated ward for infectious diseases. Another building contains the offices of the medical staff in charge. In addition, there are two sets of quarters designed for the medical officers. Away from the main building are several smaller ones, designed for kitchens, servants' rooms, and refrigerating plant, etc. It is admirably located for any purpose, being on the high land of an island which is constantly swept by the sea breeze.

Army Intelligence.—Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from October 21 to October 28, 1899:

BRADLEY, Alfred E., Major and Surgeon, United States Volunteers, will make a careful sanitary inspection of the railroad cars provided for the transportation of the Forty-fifth Infantry from Fort Snelling, Minnesota, to San Francisco.

GANDY, Charles M., Captain and Assistant Surgeon, United States Army, will proceed to New York and report to the commanding officer, Forty-third Infantry, for duty until its arrival at Manila.

Kirkpatrick, Thomas J., First Lieutenant and Assistant Surgeon, will proceed to Washington Barracks for duty with Siege Battery O, Seventh Artillery, during its practice march.

Lawrason, George B., Acting Assistant Surgeon, United States Army, will proceed to Guanajay Barracks, Cuba, for duty.

Millhoff, Clarence B., First Lieutenant and Assistant Surgeon, United States Army, is reassigned to duty at the United States General Hospital, Presidio of San Francisco.

Owen, William O., Captain and Assistant Surgeon, United States Army, is appointed as sanitary inspector of the department, with station in San Francisco.

Pick, Henry, Acting Assistant Surgeon, United States Army, will report to the commanding officer, Forty-seventh Infantry, upon its arrival in New York, and accompany it on the United States transport Thomas to Manila.

Richardson, George II., Acting Assistant Surgeon, United States Army, will proceed to San Francisco for duty in that department.

Society Meetings for the Coming Week:

Monday, November 6th: New York Academy of Sciences (Section in Biology); German Medical Society of the City of New York; Morrisania Medical Society, New York (private); Brooklyn Anatomical and Surgical Society (private); Corning, New York, Academy of Medicine; Utica, New York, Medical Library Association; Boston Society for Medical Observation; St. Albans, Vermont, Medical Association; Providence, Rhode Island, Medical Association; Hartford, Connecticut, Medical Society; South Pittsburgh, Pennsylvania, Medical Society; Chicago Medical Society.

Tuesday, November 7th: New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Elmira, New York, Academy of Medicine; Ogdensburg, New York, Medical Association; Syracuse, New York, Academy of Medicine; Medical Society of the County of Cattaraugus (quarterly), New York; Hampden, Massachusetts, District Medical Society (Springfield); Hudson, New Jersey, County Medical Society (Jersey City); Androscoggin, Maine, County Medical Association (Lewiston); Baltimore Academy of Medicine; Medical Society of the University of Maryland (Baltimore).

Wednesday, November 8th: New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Society of the Alumni of the City (Charity) Hospital; Society for Medical Progress, New York; Medical Societies of the Counties of Albany and Allegany (quarterly), New York; Pittsfield, Massachusetts, Medical Association (private); Worcester, Massachusetts, District Medical Society (Worcester); Philadelphia County Medical Society.

Thursday, November 9th: Society of Medical Jurisprudence and State Medicine, New York; Brooklyn Pathological Society; New York Physicians' Mutual Aid Association (annual); Medical Society of the County of Cayuga, New York; South Boston, Massachusetts, Medical Club (private—annual); Pathological Society of Philadelphia.

Friday, November 10th: Yorkville Medical Association, New York (private); Brooklyn Dermatological and Genito-urinary Society (private); German Medical Society of Brooklyn; Medical Society of the Town of Sangerties, New York.

Saturday, November 11th: Obstetrical Society of Boston (private).

**Births, Marriages, and Deaths.**

Married.

FOOTE—CAULDWELL.—In New York, on Thursday, October 26th, Dr. Edward Milton Foote and Miss Caroline Bishop Cauldwell.

GIBBONS—PEARCE.—In West Roxbury, Massachusetts, on Tuesday, October 17th, Dr. Sherwin Gibbons, of Lexington, Massachusetts, and Miss Anna Judson Pearce.

M'CHESNY—LINDSLEY.—In New Haven, on Wednesday, October 25th, Mr. Calvin Stewart M'Chesny and Miss Caroline Lindsley, daughter of Dr. Charles A. Lindsley, of Yale Medical School.

O'MALLEY—BANNON.—In Hoosic Falls, New York, on Thursday, October 26th, Dr. G. M. O'Malley, of Bennington, Vermont, and Miss Frances C. Bannon.
Special Articles.

THE LAW IN ITS RELATIONS TO PHYSICIANS.

By ARTHUR N. TAYLOR, LL.B.

CRIMINAL LIABILITY.

(Continued from page 633.)

Evidence of Willingness and Capability Admissible.

—While it is essential for the State, in proving the commission of this sort of a crime, to show an opportunity, it is also competent, although not essential, for it to show a state of preparedness or of willingness on the part of the defendant to render such services. It was accordingly held proper to admit the evidence of a witness who testified that, several months before the alleged crime was committed, she saw a metallic instrument in the defendant's hands, in two parts, about a foot long, round and hollow, and that the defendant said it was the best kind of an instrument for procuring an abortion, because safer than any other kind.†

Upon the trial of a physician in New York State it was held proper to admit in evidence a circular which the defendant had issued several years previously.

In commenting upon the admissibility of this circular,‡ which, it seems, was a most flagrant production, and might well be calculated to strongly influence the minds of the jury, Justice Miller, of the supreme court, said: "The circular was, I think, competent as a declaration of the prisoner that he made a specialty of this business, and was versed and skilled in regard to it. It corroborated the proof introduced upon the trial, and was a statement of himself to the effect that he made it a part of his business to attend to cases of this kind. With evidence that an abortion had been procured while deceased was under prisoner's charge, his own advertisement that he was ready to perform operations of such a character certainly tended to strengthen the testimony already introduced, and was clearly admissible." *

In the case of Commonwealth vs. Brown ‡ two women appeared upon the trial and testified positively to the details of the procurement of abortions upon them. A police officer appeared and testified as to the arrest of the defendant and produced the instruments in court which he had found at the defendant's office, also a speculum chair. Experts testified that most of the instruments exhibited were adapted to procuring the abortion of pregnant women, although none of them could be said to be so exactly designed for that purpose as not to also be appropriate for use in necessary and lawful acts of surgery.

The defendant in his own behalf testified that none of the instruments exhibited were adapted to use in producing abortion, but were all in common use in lawful and necessary surgical operations; he then explained to the jury the use and purpose of each instrument and of the speculum chair. He then offered to read to the jury from books of medical authority to substantiate his testimony, but was not permitted to do so. In answer to the evidence of the two women above referred to, he testified that the first one came to him to be treated for a tumor on the neck of her womb, and that she did not think she was pregnant; that he examined and treated her medicinally and surgically for a tumor which he discovered on the neck of her womb; and that he gave her no medicine capable of producing an abortive effect, nor did he use any instruments for the purpose of producing an abortion. In answer to the evidence of the second woman, he testified that she came to his office, in company with a man, who stated to him that the woman had been operated upon by a midwife to procure an abortion, and that at the request of the man he undertook to treat the woman, medicinally and surgically, to relieve her of a dead fetus.

The police officer, above referred to, testified that on the day after arresting the defendant, he took him before the two women and asked them if they knew the prisoner, and if they had been operated upon by him, to both of which questions they answered in the affirmative, and that the prisoner then asked them if they had previously been operated upon by another person. The prisoner's counsel objected to the admission of this evidence, but it was admitted on the ground heretofore referred to—viz., that it was an admission against interest. The court very clearly stated that employ such counsel as you think proper; but, if you are not peculiarly able, or too delicate to act in the matter, notify me, and I will protect you at my own expense.

(Signed.)

† The following is the principal part of the circular:
"Dr. ——'s female regulator; married ladies should not take it. For reference apply at his office. Office hours from 8 to 11 a.m., and from 1 to 5 p.m.

A Card—Dr. —— would respectfully announce to the ladies of —— and vicinity that he is at all times ready and happy to have a social consultation upon all matters relating to pregnancy or confinement, or in regard to lawful production of a premature birth, which, in all proper cases, he will produce in a skillful manner, guarantee an easy time, and speedy recovery. For the information of all I insert the statute in reference to the unlawful production of premature birth, which is as follows, to wit:

Every woman who shall solicit of any person any medicine, drug, or substance, or anything whatsoever, and shall take the same, or shall submit to any operation or other means whatsoever, with intent thereby to procure a miscarriage, shall be deemed guilty of a misdemeanor, and shall, upon conviction, be punished by imprisonment in the county jail not less than three months nor more than one year, or by a fine not exceeding one thousand dollars, or by both such fine and imprisonment. 2 R. S., 691, § 21.

It is a well-settled rule of law that a person can not be compelled, under any circumstances, to answer a question where the answer would convict or tend to convict the person of a crime. Ladies, your secrets are with yourselves, and yourselves alone, whether in the street, at your homes, or as a witness, and you need answer no question when the answer would in any way tend to harm you, as stated above, or to make you liable under this statute to a criminal action. And, ladies, should you ever require legal assistance in any of these matters, of course
the rule applicable in the following words: "The rule is that a statement made in the presence and hearing of a defendant, to which no reply is made, is not admissible against him, unless it appears that he was at liberty to make a reply, and that the statement was made by such person and under such circumstances as naturally to call for a reply unless he intends to admit it. But if he makes a reply wholly or partially admitting the truth of the facts stated, both the statement and the reply are competent evidence." The court in applying the rule expressed the opinion that the reply was such as to justify an inference that the defendant admitted the truth of the statements, and therefore that the statements both of the women and of the defendant were admissible.

In regard to the effect and importance which the jury should give the evidence relative to the surgical instruments, the trial judge properly instructed them as follows: "The possession by a physician of surgical instruments adapted to use in procuring the miscarriage of pregnant women would be explained consistently with that physician's innocence of any intention to use them for unlawfully procuring miscarriages, if they were instruments also adapted equally to other and legitimate uses in surgery or midwifery, unless their extraordinary number andvariety was in more than ordinary proportion to the whole number and variety of surgical instruments possessed by him, or the exigencies of his practice furnished him occasion for using; but the significance, as evidence, of the possession of any number or variety of surgical instruments adapted especially to procuring miscarriage of pregnant women, would more or less depend upon circumstances, usual or unusual, ordinary or extraordinary, attending the mode of their possession and keeping, and the exigencies of such physician's practice."

The jury in this case rendered a verdict of guilty, which the supreme court, upon appeal, refused to interfere with.

Similar to the rule of evidence admitting the circular and the instruments in evidence in the cases above examined is that under which a mother-in-law was permitted to testify that defendant had a conversation with her in which the defendant, after being informed that deceased was pregnant and desired to be relieved of her child, said, "Send her to me," and stated in effect that she had operated successfully five times on one person. Upon further questioning the witness testified that she informed her daughter-in-law of this conversation before leaving home to undergo the treatment which proved fatal. And so, in another case, the State was permitted to show by four different witnesses conversations had with the defendant extending through a period of four years preceding the act of which defendant was accused, showing a willingness and a preparedness to commit the crime for which she was then on trial. The evidence showed that to one witness defendant stated that she had the instruments with which to produce abortion, and had got rid of a number of children; that she showed witness the instruments, at the same time saying that if she wanted any help she could help her. To another she stated that she had committed abortion, and could do it again; that she had the instruments to use in doing it. And to another she stated her terms for perform-

ing such services, which she then proffered to the witness, who was in the family way, and told her she had the instruments for the purpose. The admissibility of this evidence was vigorously contested, but the court held it admissible and proper.

Dying Declarations.—From the very nature of this class of cases, dying declarations, and facts and statements forming part of the res gestae, are often an essential feature in the chain of evidence upon which the jury is asked to base a verdict of guilt. It therefore is desirable to examine more particularly the character of evidence of this sort which is admissible and proper to prove the case.

It has been heretofore shown that dying declarations must be made while in extremis, with a realization of the approaching end and after hope of recovery is abandoned. Also that they are admissible only in cases of homicide. Whether this condition does not entirely bar out dying declarations in abortion cases is a question upon which the courts of different States differ, some of them holding that they are not admissible in this class of cases at all. Among the latter are the courts of Pennsylvania, Ohio, and New York. In New York, however, the legislature has, since the decision referred to, made dying declarations admissible in this class of cases. In these States the reasoning of the court is that the crime for which the defendant is being tried is not the killing of the patient, but the procurement of the abortion, and that the incidental death of the patient does not change the nature of the prosecution, but merely aggravates the penalty. The better opinion probably is that the death of the patient from the unlawful act of the accused gives to the offense the character of a felonious homicide, and that the reason for applying the rule is quite as plain in cases of any other sort of homicide.

A dying declaration, in order to be competent, must, however, be a statement of material facts concerning the cause and circumstances of the homicide. Thus, when deceased said, "O Alec, what have we done? I shall die!" the statement was held inadmissible, as it contained no reference to the cause of death, and was not made for the purpose of explaining any act connected with the death. Nor is it sufficient that the statement should relate to a distinct fact or transaction, which is the remote cause of the act producing the death. Thus, in the case where the theory of the prosecution was that the defendant had seduced the deceased, the following dying statement was held inadmissible: "He is the cause of my death. Oh, those horrible instruments! Laws is the cause of my death, he is my murderer. They abused me terribly." In regard to the nature of this statement, the court said: "These declarations did not necessarily refer to any attempt to produce an abortion. They are as plainly referable to the former relations of the parties. If it be true that the defendant had got the deceased with child, then her declarations were such as she might naturally make in her extremity, about her seducer, without intending to charge him with any more than her seduction. The expression, 'Oh, those horrible instruments!' might indicate that instruments were used, but in no wise

* Com. vs. Holmes, 103 Mass., 440.
charges the defendant with having used them or aided in their use."* In another case † the court, in commenting generally upon the admissibility of this class of evidence, said: "The rule that dying declarations should point distinctly to the cause of death, and to the circumstances producing and attending it, is one that should not be relaxed. Declarations at the best are uncertain evidence, liable to be misunderstood, imperfectly recollected, and incorrectly stated. As to dying declarations, there can be no cross-examination. The condition of the declarant in his extremity is often unfavorable to clear recollection, and to the giving of a full and complete account of all the particulars which it might be important to know. Hence, all vague and indefinite expressions, all language that does not distinctly point to the cause of death and its attending circumstances, but requires to be aided by inference or supposition in order to establish facts tending to criminate the (defendant), should be held inadmissible."

Res Gestae.—In regard to the admissibility of statements as part of the res gestae, the general rule has been observed that the statements must be contemporaneous with the main fact under consideration. The meaning of the term contemporaneous, as here used, is not necessarily that the conversation must have taken place at the same moment that the operation was performed. Thus, when deceased left defendant's office, where the operation had presumably just been performed, walked across the street, and met a friend who accompanied her to that spot, and said, "Oh, dear, I feel weak!" the exclamation was held admissible. ‡ This exclamation, however, might have been admitted also upon the ground that it was an expression of bodily feelings. Also, conversations had relative to the purpose of an intended visit to the physician's office before departure are held admissible to show that the patient had formed the purpose of going to the defendant to have an abortion performed. Thus it was held proper to allow the roommate of deceased to testify that on the day the abortion was alleged to have been committed, she loaned deceased ten dollars, and to state what deceased said she was going to do with it, and where she was going that afternoon, and for what purpose. It was also held proper to permit the witness to testify as to conversations had with deceased on the Wednesday and Friday before the Saturday on which the operation was supposed to have been performed. In these conversations witness testified that deceased said that she understood or had found out that she was in the family way; that she had been to see the defendant about it; had been or was going to defendant to get some medicine or a syringe; that she had made an arrangement with the defendant to have an operation performed upon her; was to give twenty-five dollars, and was to return to the defendant's on Saturday afternoon for the purpose of having instruments used to get rid of the child.

Upon the admissibility of these conversations the supreme court said: "It was certainly competent to prove that the deceased went to the house of the defendant at the time it was charged in the information the abortion was produced. Upon the authorities, her intent or purpose in going there might be shown by her declarations then made or previously made; because such declarations become part of the res gestae. For it is evident the declarations were connected with the act of her going to the defendant; were expressive of the character, motive, or object of her conduct; and they are to be regarded as verbal acts indicating a present purpose or intention, and therefore are admitted in proof like any other material facts."* In the case of Hays vs. State † the evidence showed that deceased left her home and came to the house of the defendant, where she was operated upon to produce an abortion. After the operation was performed a physician was called to attend her. This physician was subsequently placed on the witness stand by the defense and testified that deceased complained of a pressing and burning in the stomach; he also testified that she said that she had "been taking some stuff," and that on the way from her home to the defendant's house, a distance of six or seven miles, something like a lump dropped from her, and that she did not know what was the matter with her. In regard to the admissibility of this evidence the court held that such part of her statements as related to her then condition, the seat of her pain, its character and extent, and any expression of mental or bodily feelings was admissible and proper; but that which she stated regarding her having "been taking some stuff" and what happened to her on her journey was a mere narrative of what had taken place before the physician visited her, and was not legally admissible, either as a dying declaration (the deceased not having been shown to be in extremis when the statement was made) or as part of the res gestae.

(To be continued.)

**Pith of Current Literature.**

Guaiacol in the Treatment of Lupus.—Funek (Monatshefte für praktische Dermatologie, 1899, No. 5; Klinisch-therapeutische Wochenschrift, September 10th) reports two cases of disseminated lupus vulgaris treated with applications of guaiacol. Both were in children three years old in whom the lupus had made its appearance immediately after an attack of measles. In the first case two months of penciling with pure guaiacol accomplished the entire disappearance of the lupus nodules, which were replaced by white scars. In the second case three months of the treatment were required. The applications were made twice a day. The author holds that guaiacol is indicated only in disseminated lupus, and that in other varieties it does not always give the best results. The treatment is painless and extremely simple.

A Case of Acute Fat Necrosis Terminating in Recovery.—Dr. L. L. McArthur (Chicago Medical Recorder, October) records a case of fat necrosis which terminated in recovery. The patient, a woman, was brought into Michael Reese Hospital in a state of profound collapse with a history of having been seized with a sudden pain in the abdomen, of intense character, resembling somewhat a hemicrurhage. The abdominal symptoms were sufficiently clear to conclude that fluid had escaped into the abdominal cavity. This fluid could be determined

by percussion, and change of position. Whether the fluid came from the rupture of an appendicular abscess, a ruptured gall bladder, ulceration from stone, or from a perforation of the stomach, was difficult to decide. From the collapsed condition, subnormal temperature, feeble pulse, sudden onset, and fluid in the abdomen, some thought it pointed to rupture of the gall bladder or a perforation of the stomach.

On opening the abdomen, after a hasty preparation, it was found that the cavity contained a considerable quantity of dark, straw-colored fluid, tinged brownish by blood, and fluid was seen to be oozing from the lesser peritoneal pouch through a small opening in the omentum. On enlarging the opening with the fingers, a large quantity, perhaps a pint and a half, of the same kind of fluid escaped. The mesentery of the intestine presented that almost indescribable, but once seen very vividly remembered, condition which we recognize as acute fat necrosis, with sharply defined yellowish or whitish-yellow areas, that looked almost like a layer of plastic lymph, but on putting the finger on it it will be recognized as being beneath the peritoneum. The finding of this fluid in the lesser peritoneal pouch led at once to the thought of the emptying of a pseudocyst of the pancreas into this pouch, as not uncommonly happens, thus making the diagnosis clear.

No routine surgical treatment has been recommended for these cases in the text-books. They generally die before treatment can be instituted. In this case the lesser peritoneal pouch was widely opened and packed with an enormous Mikulicz. After the abdominal cavity had been rinsed out with a gallon or more of hot saline solution a glass tube drain was passed down into the lower portion of the pelvis, leaving the abdomen largely wide open.

For the first five or six weeks the patient lingered between life and death, during which time masses of gangrenous tissue of varying sizes sloughed through the wide opening which the Mikulicz sac had occupied. A pathological report of these fragments, as given by the pathologist of the Michael Reese Hospital, Dr. Eisen drath, states that they were simply gangrenous connective-tissue masses. The fluid contained a ferment which, acting on starch, would then reduce the sugar test solution. These areas of fat necrosis have been proved largely to be due to the combined action of trypsin (pancreatic ferment) and bacteria, the Bacillus coli communis being found there. This brings up the point that the etiology of these pancreatic troubles may be due to the extension of this infective material to the Wirsung duct which leads into the pancreas. Just as cachradal odonitiasis may extend up into the bile duct, so it may extend to the pancreatic duct.

Post-hemorrhagic Blindness.—Theobald (Johns Hopkins Hospital Bulletin, May; International Medical Magazine, September) reports a case of atrophy of both optic nerves following severe hemorrhage of the stomach in a man of fifty-seven years. After an inquiry into the literature of the subject, and a careful consideration of the case under his observation, he concludes: 1. That the weight of evidence afforded by the ophthalmoscope points to thrombosis of the central retinal artery as the usual cause of blindness occurring in post-hemorrhagic anemia. 2. That the resistance offered to the already cæchibled blood current in the central retinal artery by the intraocular tension is an important etiologic factor in determining this result. 3. That, in exceptional instances, the ophthalmoscope indicates that thrombosis occurs not in the artery but in the central retinal vein. 4. That, in other exceptional instances, it may be that the loss of sight and the ophthalmoscopic changes which accompany it are the result of a hemorrhagic or serous diffusion into the optic nerve or its sheath (Samuelson). And here, again, the obstruction and damming back of the blood current in the central retinal artery by the intraocular tension probably have much to do with bringing about the result.

The Transference of Tactile Sensations into Visual Ones.—Dr. Frank R. Fry (Journal of Nervous and Mental Disease, August) recently related to the American Neurological Association the following very interesting case. He said that the subject was a hysterical girl, aged fourteen years, who before the time that his examinations were made, in January, February, and March, 1898, had been under the observation of Dr. George M. Tuttle, who felt secure in a diagnosis of ulcer of the stomach on account of hemorrhage, pains, etc.—in fact, typical symptoms with subsequent exhaustion. In this exhausted condition she had repeated attacks of delirium, alternating with more quiet hallucinatory states. She had frequently hemiplegic hallucination and monocular diplopia. Soon after coming under the author's observation there appeared a complete anesthesia and paralysis of the whole right side. She was anesthetic to touch, temperature, and pain tests made in the usual way.

Dr. Fry had no difficulty in reproducing the Binet experiments in this girl. He directed her to look at the wall (a plain white surface) on the left side of her bed and to tell him what kind of objects she saw there. He then traced on the anesthetic (right) arm and forearm various simple geometrical figures: triangles, squares, circles, etc. She saw them distinctly on the wall, naming them without hesitation from the first. Letters and numerals carefully traced were recognized in the same way. The tracings were lightly made with the finger nail or an ordinary lead pencil not much sharpened. When directed to look at a colored screen during the tracing she always saw the figures surrounded by the color complementary to the one before her—i.e., while looking at the blue screen she saw the figures in a red (orange?) field and vice versa. Only blue and red screens were used, but other tests revealed a perversion of color perception.

Simple objects placed in the anesthetic hand and the hand closed upon them, were seen upon the screen—e.g., an opened match box. A silver dollar was recognized as a disc. A handkerchief was tied about the wrist. She immediately announced on the screen "a dark arm and hand with a dark cloth tied around it." Other tests quite as interesting were made, serving to draw attention to an interesting hysterical phenomenon—namely, that while the subject could not recognize in the ordinary way certain sensory impressions (tactile), she could interpret them by the aid of another sensory function (visual). The author says that the experiment of transferring by suggestion a hysterical anesthesia from one area to another is a familiar one. What he had just described is similar, but it is not exactly parallel. In the latter case a more complicated psychic process takes place.

Dr. Fry said that it might not be out of place to state that great care was used in conducting these ex-
periments. The nurse was carefully cautioned; and only she and persons who understood the necessity of caution were admitted to the room when the examinations were being made. The patient never knew at any time that the tracings were made upon the arm, or that this member was used in any way in the process. She was curious to understand how the pictures were produced. She constantly besought the nurse for an explanation, who finally told her that a small magic lantern was used for the purpose. She then frequently asked me when I would allow her to see the lantern. She was an intelligent and tractable child, a very good subject for this kind of work.

Dr. H. Herrmann, Dr. Given Campbell, and Dr. M. A. Bliss, all familiar with neurological work, witnessed the examinations. Subsequently the patient was under the care of Dr. E. C. Runge at the City Insane Asylum.

The Mechanics of Fractures.—Mr. Arbuthnot Lane (Edinburgh Medical Journal for September) says that it is now several years since he showed that the accepted teaching on the subject of the mechanics and treatment of fractures was incorrect, and founded on no scientific basis whatever. This view met at first with almost universal opposition, while the accuracy of his statements was called in question. Fortunately, the advent of the X rays two or three years later furnished him with undeniable evidence that could be applied to any and every case. Briefly he demonstrated: 1. That the supposition that the surgeon is able to restore the broken bone to its normal form, or, as it is termed, to set the fracture by manipulation, etc., and to retain it in position by splints and other means, is, except in a few cases of transverse fracture, quite wrong. 2. That muscular contraction exerts practically no influence in opposing restoration of the broken bone to its original form. 3. That the whole of the soft parts surrounding the bone, whether muscles, skin, or fascia, act as ties in its length, and that the hemorrhage into and beneath these ties, with the inflammation consequent on it, are the mechanical factors which prevent accurate apposition of its fragments. 4. That the only manner in which the bone can be restored to its original form is by an operation. When the fracture has been exposed, it is possible, by the exercise of great traction upon the fragments, assisted by powerful lion forceps and elevators, to fit them accurately together. The difficulty in doing this is very much greater in the case of the lower extremity than in that of the upper; indeed, there are few operations which are more difficult than the restoration in form of the tibia and fibula, broken by indirect violence. In this variety of fracture the bones are broken so as to form a spiral, with sharp angles upward and downward. It is the very great difficulty that surrounds the operation in this particular locality that will always stand in the way of its general application. A complication of considerable importance is that of commination of the ends of the fragments. It often adds largely to the difficulties that surround surgical interference, and will sometimes tax one's ingenuity to the utmost.

One can generally fasten the perforated fragments to the shaft and to one another with silver wire, while sometimes a loop encircling the fragment and shaft may be of more service. These are, however, details. What he learned from this particular complication was, that one could utilize fragments of bone which were quite loose in the wound, providing they were secured firmly in position. This led him to employ the bones of other animals in these and similar conditions, when additional support was required. He found that it was necessary to fix such bones sufficiently firmly to prevent any movement, in order to insure their living.

---

**Book Notices.**

This work naturally covers familiar ground. Manuals on rhinology and laryngology have become very plentiful during the last ten years. It can be said that the one now under consideration covers the ground extremely well. Historical questions are omitted and in brief paragraphs the author has succeeded in setting forth with clearness the various clinical aspects of the maladies commonly met with. An occasional awkward expression creeps in here and there but does not materially mar the value of the manual.

A special feature of those portions devoted to treatment deserves commendation. Many writers, especially those for beginners, are apt to confuse their readers with a multiplicity of therapeutic suggestions. In the present instance, the author has selected those remedies and measures which in his own experience have given the best results. The use of different sizes of type in the index makes the reference to therapeutics very easy.

We would also commend the simplicity of the author's system of therapeutics. Thus he says that a normal salt solution made in sterilized water is one of the best general cleansing agents for the nose and naso-pharynx. A straightforward statement like this is refreshing in these days of complicated formulae.

This excellent little book is divided into six parts. The first part is devoted to bandaging, and describes in a terse yet comprehensible manner, which at once draws our attention and invites us to read further, the various forms of bandage, together with the proper method of applying them. Minor surgery is the title of part ii, the introductory chapter being a very interesting treatise on surgical bacteriology. The theories of aseptic and antiseptic wound treatment have advisedly been given considerable space, and we note in the description
that the operative technique of both methods has been separately pictured. The author has avoided partiality for either method and allows the reader to choose for himself.

Parts iii and iv are devoted to fractures and dislocations. The writer has confined himself to the more common ones, and has avoided all complicated forms. The treatment described is simple, and the result is a very lucid yet scientific article. Such operations as may be practised on the cadaver have been included in parts v to vii, together with a description of the instruments needed and their proper use, thus completing a volume which the student will find still more useful and instructive.

It is not the object of the author to cover the whole field of medicine; his purpose is best explained by the preface, from which we quote: “It was not intended that the compend should in any way replace the textbooks upon the practice of medicine, but, on the contrary, it was written to be an aid to the medical student at a time when practical demonstrations and ward classes were the exception in the college curriculum.” That the object aimed at has been accomplished will be evident to any one who reads this very interesting volume.

All familiar medical diseases appear under separate headings and are dealt with in a succinct yet graphic manner. The writer has devoted more space to the aetiology and pathology of disease than is usually found in so small a work.

The Medical Directory of New York, New Jersey, and Connecticut. E. Eliot Harris, M. D., Editor. Volume I. This, the first volume of the Medical Directory of the States of New York, New Jersey, and Connecticut, contains the names of physicians, dentists, and pharmacists residing within their limits. The total number of names recorded reaches 19,161, of which 11,625 are physicians, 3,798 dentists, and 4,738 pharmacists. There is also a great deal of general information, which adds materially to the value of the book.

This volume admirably suits the purpose for which it is intended. The subjects have been well selected and carefully arranged. All the more important facts in gynaecology are concisely dealt with.

A number of changes and additions appear in this edition, especially in the field of operative gynaecology, which have become necessary because of the rapid advances which have been made since the appearance of the first edition. More recent methods of diagnosis and treatment have also been substituted wherever it has been found necessary to bring the book up to date.

The author has succeeded in presenting us with a useful little book, which compares most favorably with others of its class.

BOOKS, ETC., RECEIVED.

Transactions of the Michigan State Medical Society. For the Year 1899. Volume XXIII.

Report of Commission of Medical Officers detailed by Authority of the President to Investigate the Cause of Yellow Fever.

The Shipment of Merchandise from a Town Infected with Yellow Fever. By Surgeon H. R. Carter, United States Marine-Hospital Service.

Train Inspection in Yellow-fever Epidemics. By Surgeon H. R. Carter, United States Marine-Hospital Service.

Testimony in regard to the use of Preservatives in Food Products at the Pure Food Hearings before the Committee on Manufactures, United States Senate. A Visit to the Loomis Sanitarium for Consumptives. By Guy Hinsdale, M. D., of Philadelphia. [Reprinted from the University Medical Magazine.]

The Cold Wave of February, 1899. By Guy Hinsdale, M. D. [Reprinted from the Transactions of the American Climatological Association.]

Ureteral Anastomosis. By George H. Noble, M. D., of Atlanta. [Reprinted from the American Gynaecological and Obstetrical Journal.]

New Inventions, etc.

AN IMPROVED FORMALDEHYDE REGENERATOR.

By George L. Taylor, C. E. (Bost. Inst. Tech.),
New York.

It is natural to assume that in the application of a new process to practical requirements many details, not obvious at first or apparently of minor importance, will demand attention in order to insure its successful operation. This has been especially true in regard to the methods employed in making use of formaldehyde gas as a disinfectant.

Laboratory experiments had demonstrated its germicidal power beyond controversy, but when it was practically employed in house disinfection the results attending its use were not uniformly satisfactory, as has been shown by the published reports.

Up to the present time, the liberation of gas by heat from the aqueous solution presents the most convenient and economical method of employing it in sanitary work. In order to obtain the highest efficiency, the vapor resulting from the evaporation of the solution must be discharged into the apartment undergoing disinfection at a temperature sufficiently high to insure the complete dissociation of the gas from the watery vapors; otherwise a very considerable percentage of formaldehyde will be precipitated with the condensed vapor, and the germicidal value of the solution employed will be diminished by that amount. The temperature of the boiling point is not high enough to produce the desired effect, and all apparatus operating on that principle will give unreliable results, especially in cold weather, unless an extravagant quantity of solution is evaporated.

An apparatus recently designed by the writer embodies the results of several years of practical experience with formaldehyde, and solves the problem by its simple method of superheating the vapors obtained by boiling the solution and discharging the gas at a very high temperature.

The apparatus consists of a strong copper receiver, holding about three quarts, supported over a heating lamp. Under this receiver is a copper superheating chamber connected with the interior of the dome of the receiver by a vertical tube. From the side of this chamber a brass pipe connects with a flexible copper tube of small diameter, through which the gas is discharged.

The solution is boiled in the copper receiver, and the resulting vapors collect in the dome, pass down through the vertical tube into the incandescent superheating chamber, and are discharged through the flexible copper tube. The formaldehyde gas generated by this apparatus is absolutely dry, and has been found seventy-five per cent. more powerful as a disinfectant than moist gas, as generated by other apparatus. The entire process is automatic; there are no valves or small passages to stop up and heat, which is the fault of all previous apparatus. The entire apparatus is so simple it can be readily understood and operated by any one.

Bacteriological tests made under the direction of the New York Health Department have been uniformly satisfactory, and it is now employed by that department for ambulance and general disinfecting work, supplanting various other forms of apparatus previously used.

It is also employed by Dr. Alvah H. Doty, health officer of the port of New York, in general quarantine work. The apparatus is manufactured and sold by the H. K. Mulford Company, of Philadelphia.

Miscellany.

Voluntary Suspended Animation.—The reviewer of the translation of Max Verworn's General Physiology by Dr. Frederick S. Lee, of Columbia University, in the Scottish Medical and Surgical Journal for September, says:

"The distinction between living and lifeless organisms is dealt with in an interesting and suggestive manner. He refers to the belief which seems to have existed for a long time in India, that many men, especially fakirs, have the remarkable power of voluntarily putting a complete stop to their lives for a time, and later resuming them undisturbed and unchanged. He quotes a remarkable case recorded by James Braid, surgeon, whose observations on mesmerism are well known. At the Palace of Runjet Singh—a square building which had in the centre a closed room—a fakir who had voluntarily put himself into a lifeless condition was afterward sewed up in a sack and walled in, the single door of the room having been sealed with the private seal of Runjet. In order to exclude all fraud, Runjet, who was not himself a believer in the wonderful powers of the fakir, had established a cordon of his own bodyguard round the building; and in front of the latter four sentinels were stationed who were relieved every two hours, and were continually watched. Under these conditions the fakir remained in his grave for six weeks, when the building was opened in the presence of Runjet Singh, and the seal and all the walls were found uninjured. In the dark room, which was examined with a light, the sack containing the fakir lay in a locked box which was provided with a seal, also uninjured. The sack, which presented a mildewed appearance, was opened, and the crouching form of the fakir taken out. The body was perfectly stiff. A physician who was present found that nowhere on the body was a trace of a pulse beat evident. In the meantime, the servant of the fakir poured warm water over the head and laid a hot cake on the top of his head, removed the wax with which the ears and nostrils had been stopped, forcibly opened the teeth with a knife, drew forward the tongue, which was bent backward and repeatedly sprang back again into its position, and rubbed the closed eyes with butter. Soon the fakir began to open his eyes, the body began to twitch convulsively, the nostrils were dilated, the skin, heretofore stiff and wrinkled, assumed gradually its normal fullness, and in a few minutes later the fakir opened his lips, and in a feeble voice asked Runjet Singh, 'Do you now believe me?'

"An analogous case is reported from Dublin, where Dr. Cheyne, a physician well known in scientific circles, narrates of a Colonel Townsend 'that he could die or expire when he pleased, and yet by an effort or somehow come to life again.'

"While tales of Indian fakirs are calculated to excite distrust, and impostors trade on the credulity for purposes of gain, the fact remains attested by well-
authenticated cases, that certain men can voluntarily put themselves into a state in which no vital phenomena are demonstrable by more or less careful examinations, and can awake later to normal life. In this connection the hibernation of animals must be mentioned, and also the observation of Leeuwenhoek that in the dust of houses and towns animalcules exist which are capable of drying up completely, without losing the power of awaking to active life upon being moistened with rain water.

"These rather remarkable observations may throw a side light on those melancholy cases which hospital physicians are occasionally called upon to treat, where the patient has made up his mind to die after the lapse of a certain period; and though, by careful examination, no cause can be discovered for such a prognosis, death actually does follow as predicted."

The Central Nervous System in Acute Malarial Infection.—At a meeting of the New York Neurological Society held on October 3d Dr. James Ewing read a paper on this subject. He introduced it by reporting three cases. The first was one of astivo-autumnal malarial fever, with marked cerebral symptoms and infection with a single well-defined group of parasites. The patient was a soldier who had just returned from Cuba. The stupor lasted thirty-six hours prior to death. Two days before death there were many ring-shaped organisms in the blood. The stupor began twelve hours after sporulation occurred. At the autopsy the visera showed the lesions of severe malarial infection. The capillaries of the cerebrum, cerebellum, medulla oblongata, and cervical spinal cord contained a large number of cells harboring parasites. Many capillaries were occluded by thrombi. The ganglion cells showed everywhere a reduction in size, irregularity, and splitting or loss of the chromatic bodies. Death was due to the massing of the parasites in the capillaries.

In the second case the patient had chills on alternate days for several days, and, on admission, had a pulse of 110, and was much prostrated. There were marked insonmia and mild delirium for a while; then the delirium became more marked, and finally there was coma, lasting for some time before death. There was no evidence that the coma was uremic. The temperature reached 108° F. shortly before death. On October 12th the blood contained an enormous number of ovoidal, spherical, and crescentic bodies. On the 25th, or eight hours before death, very few crescents could be seen. None of the younger forms were found. The autopsy showed moderate edema of the brain; the basal vessels were normal and very few parasites were present. The deposit of pigment in the brain was slight. Throughout the cortex the cells showed no marked change further than a uniform diminution in the chromatic substance. In many of the extracerebral lymphocytes there were peculiar structures—elongated fibres or rods with tapering ends—of undetermined nature. The chief features of this case were the prolonged delirium and coma: yet the post-mortem examination showed far less change in the kidneys than was usually seen in profound malarial infection.

The third case was one of fatal malarial infection associated with hemoglobinuria. This man had contracted malaria in Santiago in July, 1898. He was comatose, extremely emaciated, excessively anemic, and moderately jaundiced. He was at Camp Wikoff for three days prior to death. The dura and pia were distinctly jaundiced. The cerebrum, cerebellum, and medulla showed the usual injection of vessels with blood, but the vast majority of the vessels were free from the parasites. An abundant deposit of hemoglobin in the kidneys was interesting.

Commenting upon these cases, the speaker said that when the brain cortex was decidedly brownish it indicated usually the presence of a large number of parasites, but this was not an invariable rule. The majority of cases of malarial coma did not exhibit the massing of the parasites in the brain. Of eight cases in which he had examined the brain after death, in none had there been a distinct brownish discoloration of the brain. Hemorrhages had been found in some cases, as had also a moderate degree of edema. Usually the parasites were uniformly distributed in the brain and spinal cord, but a case had been reported in which they had been localized in the medulla. The number of these parasites was often enormous, and complete occlusion of the vessels was not at all uncommon. While most of the fixed pigment was found in the endothelium, the parasites were rarely seen in the endothelial cells. To the general condition of the obstructed circulation it was probably safe to refer the cerebral symptoms observed in these severe cases of malarial infection. The ganglion cells, in cases of malarial coma, had been studied, and the changes found to consist chiefly in the various degrees of chromatolysis. The dendrites were usually involved before the cell body. The ganglion cells appeared to suffer less than in the average case of typhoid fever. The mere presence of the parasites in the tissues seemed to exert no bad influence except in a mechanical way. In one of the cases reported in the paper the deepening of the comas could be apparently connected with the progressive filling of the capillaries with the parasites and the formation of thrombi. In the other two cases the parasites were few and the pigment was scanty. In both these cases the malarial infection was exceedingly severe. These cases showed that the coma of malaria was not always referable to the presence of the cerebral parasites. Of the writer’s sixty-four reported cases of malarial coma, there were five simple tertian infections. In the astivo-autumnal cases, with crescents only in the blood, there were thirty-four instances from the Montauk camp. Coma appeared to be rather frequent in cases showing only crescents in the blood. Crescents did not exhibit such a tendency to unequal distribution as the fertile forms did. From the condition of the visera found in the second and third cases reported—and this variety occurred especially in echefletic individuals in whom the disease had existed for some weeks—it seemed probable that the coma was the result of the general and profound malarial infection. The speaker did not believe that much importance should be attached at the present time to the condition of the ganglion cells in malarial infection. When the coma resulted from the massing of the young parasites in the brain, it was generally gradual in onset, and the prognosis was very unfavorable. In some cases the coma developed suddenly and was more amenable to appropriate treatment. The general clinical character of these cases indicated that an embolic process was concerned in their causation. Of eleven cases of the first class, reported by the writer, ten proved fatal. To summarize: The three anatomical conditions were: 1. The mechanical obstruction of the cerebral capillaries by large numbers of young parasites. 2. An embolic process causing occlusion of some
vessels (usually temporary) by parasites or pigmented leucocytes. 3. A general toxemia, such as might occur in other infections diseases, the blood showing few, if any, autumnal rings.

An International Scientific Language.—According to the British Medical Journal for October 14th, delegates of all the European scientific academies have met, on the invitation of the Prussian Academy of Sciences, in Wiesbaden for the discussion of some questions of international importance. Opinions are to be taken as to the possibility of establishing a uniform scientific language, and a uniform language for general intercourse—Latin for the former, English for the latter. Whether this result will be attained by the Wiesbaden meeting, whether it is attainable at all in our present multinational civilization, is very questionable. But the fact that distinguished and eminent representatives of science have come together from all European states and from America for the purpose of seeking a way toward the realization of more complete mutual understanding, thus forming, so to speak, a peace conference of science—this fact in itself is of the highest significance.

Some Present Phases of Neurology.—Dr. James Hendrie Lloyd, president of the American Neurological Association (Journal of Nervous and Mental Disease, August), in his presidential address, said that the science of neurology presented several phases at this time which were worthy of special note.

In the first place, if he mistook not, it had grown somewhat lukewarm with reference to the revelations of bacteriology as affecting problems arising in its domain. The reason for this might be due in part to some disappointment in not having realized as much as it expected from the doctrines of infection. Certainly, from a therapeutic standpoint the returns had been coming in rather slowly from the bacteriologists, and we were not prepared yet to say that we had a reliable serum treatment for many nervous diseases. We could not to-day reecho the optimistic sentiment of a former occupant of this chair, that we would yet put a stop to the funeral march of our patients through our consulting rooms. If the hypodermic syringe, loaded with animal serums of every grade and variety, was to do all this, let us bid good speed to the day when neurology would be but the handmaiden of her younger sister, bacteriology, and the syringe would have usurped the place of the microscope in our affections. In pathology, however, there was no occasion for disappointment, for it seemed almost certain that we were at least on the threshold of a wide new field in cytology, in which much that would be done would probably owe much to our advanced knowledge of infection and of vitro-chemistry.

While fully in sympathy with much of the enthusiasm which at present marked the study of the nerve cell, he thought he could see in this enthusiasm some of the extremes which periodically marked the progress of the most scientific sciences. We moved in cycles, and epochs in medicine, and like some primitive tribes we always worshipped the new moon. We were just now engaged in the cult of Nissl; we were at the high tide, as it were, of methylene blue. At another time it was the neuron theory which threatened to redeem our science. Again, we were called to trace the invisible fibrils of Apthi, which we were assured would yet bind together not only a disjointed nervous system but also a fragmentary science. He made no doubt that some of us were too much given to extremes in some of these matters, and might see more promise through the small field of a microscope than Moses saw from Pisgah. It was not exactly a good thing to use the lamp of Aladdin to illuminate the field of a microscope. We should never forget that in our histological researches we were simply numbered among those who from time immemorial had been seeking to read in dead matter the mysteries of life. The problem which had forever refused to give an answer to the Hindu and the Greek, to a Newton and a Leibnitz, would probably not yield to our more important appeals, and the dead would continue to refuse to give up its secret of life. The fact that we had a new stain that would depict the contours of chromophilic bodies, did not alter the fact that those chromophilic bodies were still without assured physiological value, and that when we looked upon them we might be merely looking upon the products of our own clumsy handiwork. We might think that we were detecting life in its innermost recesses, whereas we were merely gazing upon the wreckage of the temple.

This was not merely the pessimism of a despairing medical philosophy. Such considerations, if rightly apprehended, might serve to remind us of our true functions as investigators of disease. Pathology, it might be rightly contended, was not the science of life, but of disease; and we accomplished our true aims if we, like the archæologists, could point out unerringly what had been the normal structure from a study of its remains, and could do something to reconstruct the ruins, even if we were not able to grasp all the mysteries of the original creative force. In the domain of the nervous system this was surely a fascinating study, for in that tissue were manifested the highest functions of organic matter.

Praise for the Bay State, Hospital Ship.—The British Medical Journal for October 7th, discussing the British needs in the event of a war in South Africa, says editorially: In the event of a ship being fitted up, we would strongly recommend the committee to read the report of the medical work of the Massachusetts Volunteer Aid Association during the Spanish war. Therein is detailed the fitting out, with marvelous dispatch, in the most complete up-to-date fashion, of a hospital vessel called the Bay State, which did admirable service on the coasts of Cuba and Puerto Rico. Especially would we commend the administration on board this vessel, the efficiency of which was only equaled by its simplicity.

The Thirteenth International Medical Congress.—The American committee of the congress, to be held in Paris from the 3d to the 9th of August, 1900, met at the University Club, Philadelphia, on October 21st, at the call of Dr. William Osler. There were present Dr. W. W. Keen, president of the American Medical Association (in the chair); Dr. George M. Sternberg, surgeon-general of the United States Army; Dr. William K. Van Reyphen, surgeon-general of the United States Navy; Dr. Walter Wyman, surgeon-general of the United States Marine-Hospital Service; Dr. Horace G. Miller, president of the American Otolological Society; Dr. E. D. Fisher, president of the American Neurological Association; Dr. George J. Engelmann, president of the American Gynecological Society; Dr. H. W.
Stelwagon, president of the American Dermatological Association; Dr. Samuel Johnston, president of the American Laryngological Association; Dr. R. F. Weir, president of the American Surgical Association; Dr. A. Jacobi, president of the American Climatological Association; Dr. E. G. Janeway, president of the Association of American Physicians, and Dr. Henry Koplik, president of the American Pediatric Society.

Letters of regret at inability to attend the meeting were reported from Dr. H. P. Bowditch, president of the Congress of American Physicians and Surgeons (absent in Europe); Dr. O. F. Wadsworth, president of the American Ophthalmological Society; Dr. James Bell, president of the American Association of Genito-urinary Surgeons; Dr. H. M. Sherman, president of the American Orthopaedic Association; Dr. R. H. Chittenden, president of the American Physiological Society; Dr. B. G. Wilder, president of the Association of American Anatomists, and Dr. B. Holly Smith, president of the American Dental Association.

Dr. Osler stated that in May he had received instructions from the secretary of the congress in Paris to organize the American national committee. After consultation with Dr. W. W. Keen, the president of the American Medical Association, and Dr. H. P. Bowditch, the president of the Congress of American Physicians and Surgeons, he had nominated as members of the committee the presidents of the American Medical Association, of the Congress of American Physicians and Surgeons, and of the constituent societies composing the latter, the surgeons-general of the army, of the navy, and of the Marine-Hospital Service, and, at Dr. Keen's suggestion, the president of the American Dental Association.

Prof. Sternberg moved, seconded by Dr. R. E. Weir, that the American committee consist of the gentlemen just named. Carried.

Dr. Osler then read the following letter of instruction which he had received from Dr. Chauvaffard, the general secretary:

"Honored Colleague:

"I have the honor to state that I have sent you—

"1. A package of subscription blanks ('forms of adhesion').

"2. Some account books with stubs.

"1. Subscription Blanks ('Forms of Adhesion').

"Please distribute these blanks as widely as possible, sending them to universities, hospitals, learned societies, in a word, wherever you deem it possible to obtain subscribers to the congress.

"We have thought it wise to prepare these blanks in such form that they may be of a uniform type for all countries, which will facilitate the task of classification of the members.

"Please insist that your fellow-countrymen conform to all the directions which are therein contained.

"Pray distribute, together with our subscription blanks, announcements of your own, indicating the name and address of the representative of your committee to whom the subscribers in your country should address the subscription blanks when filled, as well as the corresponding funds.

"These subscription blanks should be collated by you and sent to us in groups of fifty, with the visiting cards and the corresponding stubs of the record book (vide infra).

"It is then understood that these blanks constitute simply a sort of propaganda, and that we shall consider as members of the congress only those gentlemen who shall have sent to your committee the amount of their subscription, and shall have received in exchange the receipt from your account book (leaflet C).

"The three account books which we have sent you (series 171 to series 173) represent each fifty subscriptions to the congress. We would call your attention especially to the detailed directions which appear on the first page of the book.

"The stubs of this book (leaflets A and B), which serve us at the same time for registration of the members and for our financial accounts, we beg you to fill out as legibly as possible, and not to forget to place the stamp of your committee at the point indicated on each of the three leaflets. This stamp will eventually indicate to us the origin of each inscription.

"This is but the first installment, and we shall be able to send you, if it be necessary, new account books as soon as you may request them. We beg you to send us the stubs as soon as each of the account books is filled, together with the amount of the corresponding subscription and the filled subscription blanks.

"We trust that these account books will facilitate the laborious task in which you have kindly lent us your assistance.

"Pray understand that we are entirely at your service to furnish you any further explanations which you may desire concerning our registration of members.

"It will thus be seen that the work of each national committee of this congress is very different from that herefore intrusted to them. Physicians in this country who wish to become members of the congress must apply to the secretary of the national committee, who will forward a blank of application, which is to be filled in and returned to the secretary, with a fee of five dollars.

"Dr. Janeway moved, seconded by Dr. Wyman, that Dr. Osler be empowered to appoint a physician as secretary to the committee, and to secure such aid as would be required to carry on the work. The question of meeting the expenses of the committee was left to the chairman. If each national committee is expected to meet its own expenses, it was agreed to call either upon the treasurers of the societies represented in the committee or upon the individual members.

"It was moved by Dr. Engelmann, seconded by Dr. Stelwagon, that the medical journals of the country be requested to aid in making known as widely as possible the conditions under which registration in the congress may be effected.

"Dr. Osler announced that he would nominate Dr. Henry Barton Jacobs, No. 3 West Franklin Street, Baltimore, as secretary of the committee, to whom all applications for blanks should be sent.

"While it is to be understood that the central committee wishes the subscriptions to be sent to the secretary of the national committee, rule 3 of the congress provides that persons wishing to be members may forward their subscriptions to the treasurer-general of the congress.

The Orleans Parish (Louisiana) Medical Society.—At a meeting held on October 14th Dr. O. Joachim reported two interesting cases. The first case was one of
complete congenital osseous occlusion of the posterior nares in a child five years of age. The condition was unilateral and the thickness of the bony mass was of about the depth of the postnasal cavity. The treatment proposed was opening the passage by removal of the bone. In former instances Dr. Joachim had experienced difficulty in keeping the passage open.

The second case was one of subphlebitis of the lateral sinus extending through the bulb into the internal jugular vein, cerebellar abscess, and periphlebitis, as the results of otitis media. The condition of the patient when first seen was very grave, showing intense pyaemia. The pulse was 140 and the patient was delirious at times. Offensive pus was oozing from the ear through a small perforation in the upper quadrant of the membrana tympani. There was no sinking of the roof of the canal. A typical mastoid operation was performed. The mastoid antrum was opened and cleared. Then the lateral sinus was opened after aspiration and found filled with pus. The incision was prolonged backward and an inch of the transverse sinus opened and found to be empty and cordlike. Just above it a cerebellar abscess of the size of a hazelnut was detected and drained. The tenderness and swelling along the line of the internal jugular vein were considered indicative of aseptic phlebitis. The vein was ligated just below the omohyoid muscle, incised, and drained of a quantity of pus. Water was then injected into the venous opening to cleanse the tract, and it was found to come freely through the wound in the lateral sinus.

On the fifth day the jugular wounds were discharging pus freely, and tubular drainage was employed. The mastoid wound was free of pus, and progressing satisfactorily. The patient rested well and was taking food, but the rise of temperature still persisted, varying from 99° to 102° F.

The Experimental Production of Tumors.—Dr. H. Pierce Clark, of the Craig Colony for Epileptics, writes to us as follows: The mystery surrounding the etiology of neoplastic growths is still far from being settled. Experimental investigation has been particularly active within the past two years. Studies upon the behavior of tissue implantation in animals have not as yet yielded all its possibilities. In this connection it is very interesting to note the series of experiments performed by A. Birch-Hirschfeld and Siegfried Garton upon the implantation of embryonic cells in adult animals, the results of which are published in the Beitrage zur pathologische Anatomie und zur allgemeine Pathologie, July, 1899. These authors report the tumorlike formation of cartilaginous tissue in the lungs and liver after the implantation of embryos in these organs in goats, rabbits, and hens. In one experiment of implantation in a hen, they found after a few weeks tissue closely resembling adenoid. Although much was found by simple implantation, yet those experiments were especially rich in findings in which some mechanical irritation was additionally applied. This new cell formation in the majority of the experiments was more or less rapidly encapsulated by the healthy surrounding tissue, and the absorption took place soon, illustrating in a striking manner how foreign to truly healthy tissue neoplastic growth as such really is.

It is very suggestive to note that in two rabbits injected with nearly full-time embryo tissue there were produced merely atrophy and local death of surrounding liver tissue. After injecting four salamanders with pieces of larva a rather large piece of cartilage was found on the surface of the liver in one salamander after forty-one days, while in the three others the results were negative.

Notwithstanding the experiments of these authors are inconclusive and not exhaustive, they are decidedly interesting and suggestive. It would be profitable to know the results of similar experiments upon a complete series of injected embryo tissue of definite ages, with, in addition, the employment of different degrees and forms of irritation of the injected organs.

The Raison d‘Être of a School of Tropical Medicine.—Dr. Patrick Manson (British Medical Journal, October 7th), in the opening address at the London School of Tropical Medicine, said:

“I have said that there is much that is special in tropical medicine. Why should this be? The answer lies at the root of our future studies. To know the cardinal facts of what is special in tropical medicine, to apprehend their bearing, and to be able to give a rational explanation for them is the first, and a most important, step in the science and practice of this department. It has occurred to me, therefore, that a few remarks on one or two aspects of the subject would form a suitable introduction to the course of studies before us.

“The principles of pathology, of diagnosis, and of treatment are the same the world over. That is quite true; but it is equally true that the details of tropical pathology, diagnosis, and treatment, and consequently the application of these principles to practice, differ widely from those obtaining in temperate climates. It is with the science and practice of medicine as with the science and practice of agriculture: success or failure in the application of principles depends in great measure on knowledge of detail. A scientific Aberdenhire agriculturist may be a successful grower of turnips in Aberdenshire; but without special training and experience he would be a failure as a coffee planter in Ceylon. Just so with medicine. It is the knowledge of detail, special experience, special training, in addition to scientific apprehension of principles, that enables the tropical agriculturist to succeed in his special climate at his special work; it is equally the knowledge of detail, the special training and the special experience, plus a scientific apprehension of principles, that will enable the tropical practitioner to deal successfully with tropical disease. A physician may be competent to deal with diseases in England but sadly incompetent to deal with disease in Africa.”

The Institute of Chemistry, Pathology, and Bacteriology, under the direction of Dr. Rudolph A. Witham (chemistry), Dr. Farquhar Ferguson and Dr. Joshua M. Van Cott (pathology), and Dr. Ferdinand M. Jefries (bacteriology), has now been in operation for about a year. It is not for teaching purposes, but for making chemical, pathological, and bacteriological examinations for physicians, also special investigations in medico-legal cases. The institute is at No. 45 East Forty-second Street.

The Southern Surgical and Gynaecological Association.—The next meeting will be held in New Orleans on December 5th, 6th, and 7th, under the presidency of Dr. Joseph Taber Johnson, of Washington. Members of the medical profession are cordially invited to attend.
THE NEW YORK MEDICAL JOURNAL, NOVEMBER 11, 1899.

Original Communications.

THE
BATH TREATMENT IN TYPHOID FEVER.
BY H. E. BALLARD, M.D.,
WATERBURY, CONN.

In a recent number of the New York Medical Journal the following is quoted from an article on typhoid fever:

"The Brand method of cold baths was not tried in any case in this series. It is very impractical in private practice, and is strenuously objected to by the patient and his relatives, and why should we employ this method when cold sponging accomplishes the same end?"

In only one point would I agree with the writer, and that is the probable objection of the relatives, which, to be sure, is a serious obstacle to overcome and will continue to be such until our physicians can educate and convince the people that this method is harmless and has reduced the mortality of typhoid fever in our largest hospitals more than seven per cent.; and could it be used more extensively in private practice I am sure we should obtain happy results.

So far as the practicability is concerned, all we need is a good trained nurse, a bath tub—which can be obtained from almost any plumber—and a neat, clean room.

In brief, I will describe the method which was used with the patient whose case I have to report.

The patient receives a full bath at about the temperature of the room every three hours when the temperature in the rectum reaches 102.2° F. or over; in the axilla, 101.5° F. or over.

The temperature of the bath will vary from 65° F. to 75° F. In extremely warm weather it may be found necessary to cool the bath by ice. The patient usually remains in the bath fifteen minutes; the duration may be lessened if the patient complains of too much inconvenience, or if his condition indicates removal. Where the temperature is exceedingly high, or rises rapidly, he may remain in the bath as long as twenty minutes. The temperature is often taken from fifteen to twenty minutes after the patient has been removed from the bath to note the reduction; this is not necessary, however.

While in the bath the patient is systematically rubbed by the attendants and the head is frequently bathed with ice water.

The tub is placed by the side of the bed, and parallel to it at the distance of about a yard. The patient’s nightdress is removed under the bed covering; his body is covered with a sheet or a large folded napkin wrapped about the loins, and he is lifted from the bed into the bath.

If the patient is asleep, he is not bathed for fifteen or twenty minutes after being aroused. If he is sweating, he is first thoroughly dried. The patient’s head and shoulders should be supported by a pad while in the tub. The water should cover the entire body to the neck. Upon entering the bath he receives an ounce of spirits. After eight or ten minutes in the bath shivering usually takes place, and the face and extremities may become slightly cyanotic. While the patient is in the bath his bed is covered with a rubber sheet; over this are placed a blanket and an ordinary sheet. The patient is lifted out and laid upon the bed thus arranged, tucked in the sheets, and covered with a blanket. In the course of fifteen minutes he is thoroughly dried and the night-dress replaced.

About the time reaction is established the patient receives nourishment, and usually falls into a natural sleep.

If there should be marked cardiac asthenia or delayed reaction, the patient should be at once dried and given a little hot sling and a hot-water bag at the feet. Friction to the spine will also give comfort where there is much chilliness after leaving the bath.

For patients in private practice the tub may be filled with water once in twenty-four hours. If at the end of three hours the temperature has not risen above the given point, the patient is not disturbed until another three hours have passed, unless nervous symptoms arise, or there is manifest high temperature present, in which case he may have the bath sooner.

The principal contraindications for the bath are intestinal hemorrhage and peritonitis.

Whenever there is evident indication for medicinal treatment, it is, of course, used, but in the vast majority of cases there will be no call for a single dose of medicine.

Such, in brief, is the Brand method, with a few exceptions.

The effect of the individual bath upon the nervous and circulatory systems is most beneficial; dicrotism ceases, and a muttering delirium will give place to quiet sleep under the soothing influence of Nature’s remedy.

The case I have to report was a well-marked one, and was seen about the sixth day. The Brand method of treatment was immediately begun and continued for forty-eight hours; baths were given at periods varying from three to six hours, the temperature reaching a point of 105.5° F. The drops in the temperature, taken twenty minutes after baths, were from 2.5 degrees to five degrees. At this point the temperature varied from 101° F. to 102° F. for four days, when it began to rise, and reached a point of 103.5° F.

For experimental reasons, I used the cold sponge and wet pack. The greatest reduction we got from this procedure was from one to 2.5 degrees; this plan of
treatment was continued for five days, when the temperature again reached 105.5° F., and the patient was again put into the tub, with baths every three hours when necessary. This was continued for four days. After this period the temperature did not rise above 102° F. again, and the patient made an uninterrupted recovery. During the entire course of the disease the patient did not receive a single dose of medicine, except stimulants, while in the bath. His pulse was good throughout; there was little if any tympanitis present, and at no time was he delirious. The eruption was very marked all over the body; epistaxis was present at the beginning; the bowels were never troublesome. He received three enemas during the course of the fever. The diet throughout consisted of raw milk; from three pints to two quarts during twenty-four hours. I might say here that my patient asked for his baths, instead of objecting to them. I wish I had more cases in private practice to report. My experience with this method has been confined almost wholly to the hospital, but every little helps, and I hope the day is not far distant when we may see this method used extensively in private practice. The great objection to it arises from the relatives, and this our physicians must overcome.

**THE RELATION OF PATHOLOGICAL CONDITIONS IN THE ETHMOIDAL REGION AND ASTHMA.**

**CLINICAL PHASES.**

**BY CLARENCE C. RICE, M. D.**

The first division of this relationship—namely, its pathology—seems to us to be far the most important, and it easily covers the more difficult portion of the field. To trace an intimate relationship, pathologically, between two disorders at first sight so far apart as ethmoidal disease and the disturbance in the bronchial tubes known as asthma is not an easy task. When we shall have arrived at a thorough understanding of the pathological relation between these two affections it will be comparatively easy to state their clinical expressions, because, although diseases of the ethmoid present numerous objective forms, the symptomatology is not so varied.

We had expected that the description in the preceding paper of the pathological conditions to be found in ethmoidal affections would be most attractive, and we have not been disappointed. More progress has been made during the past five years by this association in the investigation of the various forms of inflammation which attack the ethmoidal region than in any other affection which we have studied. This is true not only because so much attention has been paid to it, as can be seen by consulting the last six volumes of the Transac-

**tions, but because, also, the paucity of our knowledge regarding ethmoidal disease has afforded a great stimula-

tion to this investigation. We are certainly obtaining a very clear insight into the pathological manifesta-

tions here, and shall soon be able to accurately diagnosticate not only the kind of inflammatory process, but also appreciate the stages through which it has passed and predict its future behavior.

I find the division of the subject which has been assigned to me a difficult one to treat. It would not be a hard task to present to you the clinical phases of the different varieties of ethmoidal disease, nor to describe an asthmatic attack, but to present a true picture of the symptoms of both in their relation to each other is not an easy matter. When this subject was first presented to me I reviewed my recent cases of ethmoidal disease—many under treatment at the present time, perhaps numbering as many as twenty-five—and I was disappointed to find that not a single one had ever been complicated by asthma in any form.

I can not positively state that bronchial asthma de-

pending upon nasal disorder is more rarely seen now than five years ago, when so much was written in regard to this relationship, when your attention was so often called to it, and it was so freely discussed by your society, but I certainly have seen far fewer cases during the past two or three years. I should say that without exaggeration I had seen two dozen cases of ethmoidal disease during the past two months, and not one of them had ever had an attack of asthma. But it should be said that in only two of these cases was there any appearance of myxomatous degeneration. There was no pedunculated polyp. So that, in looking for data on which to base the relationship between ethmoidal disease and asthmatic symptoms, I am obliged to refer to cases which have occurred in practice longer ago.

Looking at the subject from the asthmatic point of view, it seemed apparent that where a clinical relation-

ship was to be traced between it and intranasal disease, in the very large majority of cases there was present either marked myxomatous degeneration, so called, or well-developed polypi. If my clinical experience is correct, hay-fever asthma does not bear an intimate relation-

ship to chronic ethmoidal disease except where either sessile or pedunculated polypi are present. We should expect this to be the case, because ethmoidal disease sufficient to produce attacks of asthmatic breathing would probably be of an aggravated chronic type, and the production of asthma would more reasonably occur at any period of the year, and not during the sum-

mer months alone; so that where there exists the relation of cause and effect between ethmoidal disease and asthma, the asthma would be likely to be of the perennial rather than the periodic type. Undoubtedly dur-

ing an exacerbation of what MacDonald calls "parox-
RICE: DISEASES OF ETHMOIDAL REGION AND ASTHMA.

If a close clinical relationship existed between asthma and simple enlargement of the middle turbinated bone, either with or without suppuration and necrosis, it certainly could not have escaped our observation, because ethmoidal disease in nearly all its pathological forms is, I believe, a very common affection. But we do not often find asthma with a simple chronic enlargement of the middle turbinated bone, no matter how great this enlargement may be, so that it would seem necessary for the production of asthmatic breathing that there should be present either the extra irritation of vegetable emanations, the result being so-called nervous asthma, or that, on the other hand, for the production of perennial asthma, it is necessary that the nostrils should be quite thoroughly blocked with polypi and that there should be present the usual profuse catarrhal discharge, not only in the nose but also in the pharynx, larynx, and bronchi. Under such conditions it will, I believe, be exceedingly difficult to prove that asthmatic symptoms are not rather an exhibition of a catarrhal bronchitis than that they are reflex exhibitions of nasal disturbance.

Since asthma is more frequently associated with nasal passages blocked with polypi, we are led to reflect whether the coexistence of asthma and ethmoidal disease is not due largely to mechanical obstruction which necessitates mouth breathing, and to the supervening chronic catarrh of the entire respiratory tract. If this were true, why should we not have a chronic asthmatic condition so long as the nasal passages remain closed? We undoubtedly do have sometimes the production of a chronic bronchitis and emphysema by reason of completely blocked nostrils. The temporary character of asthmatic symptoms associated with nasal obstruction is to be explained in a number of ways. They are more likely to occur during the acute congestive exacerbations which are common to nasal obstruction of all kinds during rapid changes in atmospheric temperature; and, in fact, may be due to any derangement of the circulatory or digestive apparatus. All or any of these may be adequate to furnish just the additional irritation to the chronic process sufficient to develop the asthmatic attack. That it is the amount of nasal obstruction rather than the form has to my mind been emphasized within the last few weeks, because where I found only one case of asthma out of fourteen cases of ethmoiditis in all forms excepting that of myxomatous degeneration, I have, on the other hand, found that two cases out of five patients having polypi have had numerous asthmatic attacks. I do not believe the proportion is usually so large. I may state it as an interesting fact that I have a record of asthmatic symptoms in two out of six cases suffering from what later was found to be adenocarcinoma of the nasal passages.

MacDonald says: "There is no manner of doubt that a considerable number of asthmatic patients suffer from intranasal disease, the majority of which are

ysmal sneezing" (preferring this title to that of hay fever, because the former is a constant symptom), the ethmoidal region is as acutely congested as other portions of the nasal passages, and probably affords its proportion of the causation of reflex bronchial spasm. It can not be proved, also, that swelling in the ethmoidal region does not produce greater irritation than congestion farther forward. But it is all problematical. As I have said, however, chronic ethmoidal cases other than those with polypi or myxomatous degeneration have not been hay-fever cases or periodical asthma patients. So true is this that I have felt at times that chronic ethmoidal disease afforded some degree of immunity to the various reflex phenomena which are associated with very sensitive nostrils. We certainly do not see extreme sensibility in the nasal passages of chronic ethmoidal patients. It is particularly true when suppuration and necrosis are present. I do not find, in looking through our Transactions and examining the cases of ethmoidal disease recorded by members of this association, that they frequently allude to asthmatic complications. I am not speaking now of general statements, but of reports of clinical cases. Many of our writers, speaking of the symptomatology of ethmoidal disease, allude to various reflex phenomena, but certainly the frequency of asthma as a symptom does not seem to have impressed them.

This one exception must be made to the statement that ethmoidal diseases are not often associated with periodical asthma, for we all know of frequent instances where we have seen acute attacks of asthma during the hay-fever period in patients whose nostrils were filled with polypi, which is one of the manifestations of ethmoid disease. But patients with this condition of the nasal passages are apt to be affected by asthma at any time of the year, and we think are more subject to such attacks during cold, damp weather than during the summer months. In my cases of hay asthma, or periodical asthma, I have much more frequently found no nasal disorder more grave than the ordinary small degrees of deflection of the septum or of exostosis, or moderate turbinated swellings, which we see in the nostrils of nearly all our patients.

Bosworth says, in speaking of the nasal lesions in his asthmatic cases, that they were either nasal polypi, deflections of the septum, or hypertrophic rhinitis, and consequently does not mention ethmoidal disease except as manifested by polypi. Although he says that in considering a hundred and fifty cases of ethmoidal disease between ninety and one hundred of them showed marked symptoms of vasomotor disturbance, either in the form of hay fever, asthma, or nasal hydorrhea, he does not state what form of ethmoidal disease was present in these cases; but, taking into consideration his first statement, that his cases of asthma were associated with polypi, we suppose that the ethmoidal disease presented itself in this form.
polypi usually associated with suppuration." The question naturally arises, Why should polypi be more frequently associated with asthma than other conditions of the ethmoid unless it is on account of the greater nasal obstruction and the large amount of general catarrh, and the greater degree of interference with the nasal respiratory function? Certainly the conditions are as favorable for producing nervous irritation and vasomotor disturbances where the entire middle turbinate body is so large as to be wedged between the outer wall and the septum.

MacDonald makes another remark which I am quite in accord with—namely, that it by no means follows that the nasal disease is the cause of the asthma. He believes that the two regions are simultaneously involved in a chronic inflammatory process which finds its expression in the production of polyps in the nose and a bronchial catarrh and spasm in the lower respiratory tract.

MacDonald also makes this significant remark—significant because I have always believed that it is exceedingly difficult to determine whether asthmatic symptoms should be considered a reflex exhibition of nasal irritation or a symptom of an existing acute bronchitis. He says:

"It must be mentioned that polypus is by no means uncommon in patients of middle or past middle life who suffer from bronchitis, and who are, consequently, said to be asthmatics."

Dr. Roe, in a discussion on this subject some years ago, remarked that in all cases of asthma caused by disease of the nasal passages we should distinguish between those in which the asthma is dependent upon diseased conditions in the nasal passages alone and those in which there is also a diseased condition of the general respiratory passages.

I have already said that the probability of an asthmatic attack occurring with nasal disease seems to be in proportion to the degree of nasal obstruction. The nasal passages are not much obstructed in any form of ethmoidal disease except where myxomatous degeneration is present or polypi are developed. In a chronic ethmoiditis which expresses itself in such enlargement of the middle turbinate bone that it extends from the outer wall to the septum, unless there also exists deflection of the septum or an enlarged inferior turbinate bone, we seldom have noticed asthmatic symptoms. And here it seems to me that the complicating asthma is due to a combination of these several obstructing elements rather than to the irritation produced by the enlarged middle turbinate alone. My feeling is that irritations emanating in the anterior part of the nostrils in the way of contact between the septum and acute enlargement of the inferior turbinate bone are more potent in producing reflex phenomena in the respiratory tract generally than enlargements in the region of the ethmoid.

Speaking of a simple chronic enlargement of the middle turbinate bone without polypi, I recall but two instances in which there were asthmatic symptoms, and both of these occurred at any time during the year. There was a general laryngeal catarrh, and I can not say that there was not a chronic bronchitis in both. MacDonald speaks of this pathological condition as occurring in anemic women. I have seen this class of patients principally in dispensary practice, and have always felt the condition was largely dependent upon unwholesome living. Nor has my attention been called to any special relation between ethmoidal disease and asthma, even where the middle turbinate extended downward sufficiently to come in contact with the inferior turbinate bone. These conditions of the middle turbinate all represent a very chronic process, and we may more reasonably expect to find such phenomena as asthma during a more active inflammatory condition. For it can not be denied that the greater the sensitiveness of the mucous membrane, as indicated by color, sneezing, spasmodic cough, and larynation, the greater will be the opportunity of producing asthmatic attacks. We are able during an attack of asthma to trace the abnormal congestion present not only through the nasal passages, but down into the trachea as far as we can see. I produced an asthmatic attack not long ago by applying chronic acid to the anterior surface of both enlarged middle turbinate bones.

I do not know that it would be of any service to this paper to call your attention for a moment to the classification of ethmoidal disease which Dr. Bosworth has presented to this association. His first division is a myxomatous degeneration without purulent discharge; second, an extracellular myxomatous degeneration with purulent discharge. Both of these, it seems to me, are one and the same process. The third division is a purulent ethmoiditis with nasal polypi, and I do not see why this can not also be considered a later stage of the first and second varieties. The fourth variety, intracellular polypi without pus discharge, is hardly to be dignified as a different kind of inflammatory process, but simply explains that for some reason the pathological process has begun in the internal rather than in the extracellular portion. And the fifth variety, intracellular polypi with pus discharge, differs from the fourth only as to the matter of suppuration.

I believe it to be unwise to complicate the study of inflammatory action in this region by endeavoring to subdivide it into many varieties, or even into many stages of the same variety. I am in full accord with one of the conclusions of Dr. John Mackenzie,* in which he says, speaking of the pathological changes in the ethmoidal region, that they represent successive stages of the same affection, and therefore divisions and subdi-

---

* Transactions of the American Laryngological Association, 1896, p. 266.
visions of ethmoiditis tend to introduce elements of confusion into our pathological conception of the disease.

We should not lose sight of the great frequency of the non-suppurating, chronic hypertrophy of the middle turbinated bone. With great enlargements of the middle turbinated bone there is probably always a chronic inflammation of the ethmoid as well; perhaps the process begins in the ethmoid—the whole perhaps the result of frequent acute inflammatory attacks in this region. It is quite possible that in nearly all severe acute coryzas the ethmoidal region is as much affected as other portions of the nasal passages. We speak of this chronic hypertrophy of the middle turbinated because it is so common, but we have not often found it associated with asthma. We see it in patients where the inferior turbinated is atrophied, and where there is present, if not a general atrophic rhinitis, at least a dry mucous surface. I have thought that enlargement of the middle turbinated under these conditions might perhaps reasonably be called a compensatory hypertrophy which to some extent stood in the place of the atrophied inferior turbinated process.

There will always be difficulty in deciding whether in a given case the middle turbinated bone should be considered hypertrophied, for as with the inferior, these bony processes do and should bear a certain relation to the size of the nasal passages. But when the middle turbinate has become so enlarged as to press upon the septum and produce nasal obstruction and neuralgic pains, it is safe to assume that the pathological condition is going too far.

When we approach the other forms of ethmoidal clinical disease we encounter great difficulty in any attempt at a classification, and I do not believe that the pathological conditions which are found here always follow any regular sequence, as we might wish in order to thoroughly appreciate the behavior in each and every case. Certainly the presence of polypi is not necessary to the production of suppuration and necrosis, because all the time we have suppurating ethmoiditis without the slightest tendency to the formation of so-called myxomatous tissue. It is true that where polypi do exist there is usually purulent discharge. But this may have existed before the development of the polypi. Simple suppurating ethmoiditis is in my experience much more common than where it occurs with the existence of polypi. In other words, taking into consideration the very large number of cases of ethmoidal disease which we see, those in which myxomatous degeneration has taken place are comparatively rare, and, since this is the form of ethmoidal disease which is usually associated with asthma, it can not be said that the coexistence of ethmoidal disease and asthmatic symptoms is very common.

In the many discussions by this association regarding the relation between intranasal disease and asthma two expressions of opinion have usually been apparent.

One, that bronchial contraction was a nervous phenomenon, thoroughly reflex in its character, probably produced by some derangement of the vasomotor system. The other opinion has been that this relationship is not nearly as subtle, but that the complication of the bronchial irritation with the nasal disturbance was rather to be explained along the more usual process of an extension of congestion and inflammation. I think we can safely add that where the nasal passages are largely obstructed and the nasal function is for the time being abrogated, it is quite possible that the evil effects of mouth breathing and the contact of unsuitable air with the bronchial mucous membrane are competent to be additional sources of irritation. It is much safer to give to each one of these causes due credit than to hold the opinion that nasal disease of any variety always exerts its influence in a reflex way.

Where asthma occurs with badly obstructed nostrils, the first irritation to the bronchi may be reflex, or nervous, and transient; but if the nasal obstruction remains for a long time unrelieved, and especially if this nasal obstruction is due to polypi, and there exists suppuration, there will very soon develop a general catarrhal bronchitis, which in itself may produce asthmatic symptoms.

It may be that we as specialists see comparatively few cases of asthma other than the hay-fever variety, and it is quite possible we should find ethmoidal disease in the perennial asthmatic cases which consult the general physician.

I have not endeavored to cite the clinical phases of either asthma or ethmoidal disease, because you are all so familiar with them, and so have, I fear, succeeded only in presenting to you a few desultory observations in regard to the relationship of diseases of the ethmoid to disturbances of the respiratory region.

From what has been said it would seem necessary that where asthmatic symptoms coexist with ethmoidal disease there should be present either nasal passages blocked with polypi, and hence mouth breathing, with a general catarrh, or else very acutely inflamed conditions which would produce a neurotic asthma by vasomotor disturbances.

123 EAST NINETEENTH STREET.

The Simple Electric Bath for Rheumatoid Arthritis.

—Dr. James Taylor (Clinical Journal, October 11th), in a clinical lecture, says that a condition of a very painful nature is rheumatoid arthritis, and very great relief is often afforded in that disease by galvanism applied in the electric bath. This is simply an ordinary bath with one of the poles immersed in the water and the other stroked over the painful parts. So there is nothing mysterious about the electric bath; it can be given with an ordinary bath and an ordinary galvanic current.

There is nothing very new, of course, in this, but it is well to remind the general practitioner of its simplicity of application as well as its efficacy.
THE

RELATION OF PATHOLOGICAL CONDITIONS IN THE ETHMOID REGION OF THE NOSE AND ASTHMA.

CLINICAL PHASES

By E. Fletcher Ingals, M. D.,

CHICAGO.

I had no thought of saying anything upon this subject, but Dr. Casselberry this morning said to me that it was necessary for some one to take the place of Dr. Rice on the programme, and I consented to do so.

We are all familiar with the peculiar clinical phases of this disease. I was much interested in the pathological conditions as presented by Dr. Swain, and it seems to me there is much food for thought in his paper, and that it may aid us frequently in the scientific treatment of this affection. I have not so frequently observed as others the connection of this disease with affections of the nose, although I have seen it occasionally.

I have seen some cases of asthma relieved promptly by removing polypi, or relieved more slowly, as suggested in the paper, the patient gradually improving for a few days or weeks, and suffering no recurrence of the attacks until the polypi had returned.

As bearing upon the causation, the inhalation of various substances is a well-known factor. I have seen several cases in which the patients were affected with asthma as a result of riding behind a horse or caring for horses. I had one peculiarly unfortunate patient whose business was teaming, and whenever he went near the stables he had an attack of asthma. I have known patients who could ride on a dusty road behind oxen, or who could ride a bicycle, no matter how much dust there might be, but who could not ride behind a horse. So the emanations from various animals cause peculiar cases, which are familiar to all of you. One especially interesting feature I have noticed in two or three patients who have assured me that they had asthma in one lung only. They were all intelligent patients whom I could rely upon as making correct statements, but I did not see them at the time of the asthmatic attack.

A physician, who practised in this city until a few years ago, told me that he had for many years been subject to asthma in almost any part of the city, but that when he came downtown and went to the sixth story of a hotel he experienced complete relief. At that time the buildings were not so high as now.

I recall one patient who suffered terribly from asthma for several years. She lived in a brick house, which was in every way healthful, so far as we could discover. She moved three or four blocks away into another brick house and her asthma disappeared and did not return again for many years.

A still more interesting case than the one just narrated was related to me by one of my colleagues. It was the case of a patient who suffered from asthma when sleeping in one part of the house and not in the other. The beds were the same, also the pillows. One part of the house was built of brick, the other of wood, and the material used in the construction was in some way the cause of the asthma.

An interesting instance of asthma and the indifferent means by which it may be stopped was told me by another of my colleagues, whose daughter had been under my care for obstruction of the nasal passages. She had asthma at certain times of the year, but the relief of the obstruction did not, in her case, cure the asthma, as I have seen it do in other cases. However, it gave her considerable relief. This girl was about fourteen years of age. She seldom had asthma when in the city, but in the country she had frequent attacks.

One night this hard-working physician went to his country home to take a little rest. During the night the baby began to cry, the mother began to scold, the girl began to wheeze terribly, and the physician was called upon to get up and straighten matters out. He got some water to quiet the child, but in pushing by the side of the bed the springs were loosened and fell with a great crash, which stopped the baby’s crying, the mother’s scolding, and so frightened the eldest daughter that the attack of asthma was cured instantly.

In some patients with obstruction of the nares, cocaine, by taking down the swelling, will promptly relieve the asthma. I have been interested also in the relief of asthma by the inhalation of a spray containing cocaine. The question arises whether or not its effects are the same as in the nares, in taking down swelling of the pulmonary tissues; or does it act simply as a stimulant of the vasomotor system? I have known patients to obtain great relief during the asthmatic attacks of hay fever from inhaling the spray of a nostrum which analysis shows contains about three per cent. of cocaine and five per cent. of nitrite of sodium, with other ingredients which seem to be of no consequence.

THE PATHOLOGY AND THERAPY OF CANCER, WITH SPECIAL REFERENCE TO CANCER OF THE STOMACH.

By Augustus C. Bernays, St. Louis.

(Concluded from page 657.)

If a radical operation is judged to be anatomically possible by the operator, the question arises, What is the prognosis quod vitam? In other words, What per cent. of chances has the patient to survive? The question as

* Read before the American Laryngological Association at its twenty-first annual congress.
to the functional disturbance must also be taken into account: the surgeon must consult with the patient about the matter; both of them must consider the proposition, and must answer the question, Is life worth living when certain functions are impaired or lost? In answering this question we must remember that we are dealing with a disease which is usually rapidly fatal, and if it involves certain localities, as, for instance, the throat or the pylorus or the bladder, is often the cause of extreme suffering before it produces death. Some of these cases are also offensive, not only to their surroundings but to themselves, by the intolerable odors which they emit.

My object in this paper is to advocate early and radical interference by operative extirpation, and to combat the tendency of some surgeons to operate only on quite simple cases. I can not admit that the selection of only simple cases for operation is a proper point of view. No doubt the only way to get good statistics is to avoid mortality after one’s operations. This desire to avoid mortality always strikes me as a selfish and unprofessional, yes, even a mercenary aim. What are you going to do with the poor fellow who is not operated on because the surgeon fears the possibility of a fatal issue? Has he not a right to demand of you that you give him his only chance? I can not see that we have a right to refuse an operation if the disease can be removed, unless the outcome would be a hopeless functional result or almost certain death at the operation or soon after it.

Knowing that cancer is curable if totally extirpated, and knowing that it is fatal if not totally removed, I have arrived at the following method of dealing with patients who seek aid from me when they are afflicted by a cancer:

1. When the disease is clearly curable and the danger is slight, then I feel it my duty to urge the operation, and insist on an immediate performance of the same, and represent the prospects of a cure as highly probable.

2. When there is considerable involvement of the lymphatics I do not strongly urge the operation, but tell the patient that the chance of a cure, though small, still exists, and, in fact, feel it a duty to make the attempt at a radical extirpation.

3. When the danger of an operation is very great, but where I still think the removal of all involved tissues can be completed—I mean by that where the operation is anatomically thinkable—I present the grave dangers of an immediate death on the operating table, and, though holding out but little hope of a cure and only a probable prolongation of life, I still give enough encouragement to inspire the patient with some expectation of being benefited. As a rule, I find that these patients will decide to have the operation done.

4. Finally, in anatomically impossible cases I do not think it is justifiable to refuse to operate in some fashion if, after knowing the truth as to the hopeless- ness of the condition, a patient demands that an operation be done. In these cases the psychical effect of even an imperfect partial removal of the offensive cancer sometimes is very beneficial, and puts off for months the inevitable morphine syringe which we are compelled to use during the last weeks.

The time allotted to me will not permit of taking up different forms of cancer in different regions of the body, and I have chosen to present to you the rules that should govern us in only one special region. Let us consider now the management of cancer of the stomach, one of the most frequent and most surely fatal forms of the disease. In the management of gastric cancer two different objects are to be aimed at and two entirely different operations must be borne in mind in treating a case. If we can reasonably hope for a cure, then we at once contemplate the excision of the diseased tissue, because if there is a chance of a cure we have a right to undertake a dangerous operation.

The operation will be an excision or resection of the pylorus or of a larger part of the stomach, or even of the whole stomach. If a cure is not thinkable—i.e., is anatomically impossible—then we must perform an operation which will ameliorate the patient’s condition by overcoming the stenosis and by preventing starvation. The operation we will choose for this purpose is one of the forms of gastro-intestinal anastomosis, gastro-jejuno- stomy and gastro-duodenostomy, the two operations which come into practice. I do not intend to discuss the various technical modifications of these two operations, but will speak of the diagnosis and indications for surgical interference. I regard it as most desirable that from time to time an accounting be rendered to the general practitioner about the results of the treatment of cancer by surgical operations.

I am of the opinion that it is the duty of every physician at the present time to call his patient’s attention to the possibility of a radical removal of his disease by an operation. Unfortunately, the diagnosis of cancer of the stomach is not always easily made in the early stages.

We must not wait until a tumor can be felt. We must recommend an operation if there are symptoms of chronic stomach trouble in persons above middle age which point to ulcer or stenosis. An essential pointer is given us if we can detect malnutrition and indigence accompanied by a perverted chemical action. I refer especially to the absence of hydrochloric and the presence of lactic acid in the gastric juice, together with coexisting signs of retention of contents in the stomach, which indicate pyloric stenosis. We dare not forget that even when the chemical action of the stomach is normal there may be malignant disease.

In a case in which I made the first total excision of the stomach done in America the diagnosis of cancer
had been made by the attending physician, although a tumor could not be plainly made out. The patient had been carefully treated for several months on the supposition that he had a gastric ulcer. He had a number of hemorrhages of almost pure blood. At the operation I found a most extensive tumor along the minor curvature. There was no stenosis, and the pylorus was entirely free from disease. In another case recently operated on the diagnosis of cancer was made by competent physicians without a knowledge of the presence of a tumor, and there was no dilatation of the stomach. At the operation I found an enormously large, far-advanced pyloric cancer, with narrow stenosis. The tumor was adherent to the pancreas, extended upward toward the hilum of the liver, and involved about half of the minor curvature. You see that it will not do to wait until a tumor can be palpated, and I regret that I sometimes did not operate early enough because I could not feel a tumor.

The exploratory incision is free from danger, and by its means we can make an early diagnosis and sometimes render good service even if we should find a nonmalignant trouble. The only case in which harm can be done by the exploratory incision is when we make it upon patients too nearly dead from starvation and cachexia.

Persistent, progressive stomach troubles in persons over forty-five years of age are much rarer than is usually accepted by physicians, unless there is a mechanical foundation for them. This foundation will be found in an existing stenosis or ulcer of a cancerous nature in the vast majority of cases. The "sympathetic" stomach troubles due to gallstones, floating kidney, Bright's disease, or some form of constitutional disease having been excluded, nothing remains for us but the diagnosis of gastric cancer.

The trouble which most commonly is confounded with cancer is simple ulcer. But here, as a rule, we have hyperacidity, hyperchlorhydrosis. But we may console ourselves about this matter because even in benign ulcer operative therapy is often the only correct, the only successful course. In this direction in recent years good work has been done by Leube, of Wurzburg. In 1897, at the congress of surgeons, he threw much light on the subject by giving his large experience in one thousand cases of gastric ulcer treated by internal medication. Leube found gastric hemorrhages in forty-six per cent. of these cases, and still there was only a mortality of four per cent. In a series of five hundred and fifty-six cases, six died of uncontrollable hemorrhage and six from perforation and peritonitis. In three fourths of all his cases of benign ulcer Leube achieved a complete and permanent cure by means of a dictetis and medical treatment lasting four or five weeks; one and a half per cent. remained unimproved, and two and four tenths per cent. died. Leube thinks that the remaining twenty-one per cent., who had only been improved, would have been cured by a repetition or continuation of the treatment.

Leube, who is not a surgeon, recognizes the following indications for surgical treatment:

1. Repeated hemorrhages.
2. Severe pain and frequent regular vomiting which persists after medical treatment and dieting.
3. Perforation of an ulcer of the stomach.

We are glad to record the fact that a most competent medical authority recognizes that surgery is indicated even in benign ulcers, and I hope you will agree that surgery must not be appealed to as a last resort. The rank and file of the profession must give up the idea that surgery is a last resort and familiarize themselves with the idea of calling the surgeon early. It is just as easy to prescribe a surgeon for a patient as a dose of morphine.

Billroth said that there must be more surgery in the practice of medicine, and when directly understood this thought is entitled to great weight. I am perfectly willing to be used as a tool by the physician, and I think all normally constituted surgeons will recognize that the physician's calling is more arduous than that of the surgeon, because really the diagnosis of internal diseases postulates a much more scientific education and training than is essential to the surgical specialist.

The most important indication for surgical interference is a suspicion that the case is one of cancer. Even where the suspicion of cancer is not pressing the exploratory operation is indicated. The smaller the cancerous tumor the more chances we will have of a radical cure by its removal. I should consider it a most urgent indication to open the abdomen if a competent physician suspected cancer in a patient whom he had carefully examined and treated for a month or two. Should we find a simple ulcer after opening the abdomen, no harm will have been done, and the case will have been cleared up, and either medical or surgical treatment can be rationally and satisfactorily carried out. When in doubt, operate!

In looking over the statistics of operations in gastric cancer, the important fact is found that we can now furnish the proof that patients from whom we have removed parts of the stomach, yes, even the whole stomach, for cancer, are enabled to digest and assimilate food and keep well nourished.

I will quote the statement made by the great surgeon Kocher in summing up his entire experience in the surgical treatment of cancer of the stomach by resection. Up to the summer of 1898 he had done fifty-seven excisions of cancers of the stomach. There were then twelve of the patients living. Four others had lived in a good state of health over three years. One man was drowned while bathing and in perfect health. One woman died of a cicatricial stenosis, and Professor Langhans, who made the autopsy, could find no trace of a return. One man died after a year's good health,
in an insane asylum. One woman died four years after
the operation from an unknown cause, but Professor
Kocher thinks it possible that she had cancerous
glands somewhere in her abdomen. Besides these four
cases there are five permanently cured patients. These
are in the enjoyment of perfect health. One of them was
operated on in 1888, one woman in 1893, one man and
one woman in 1895, and one man in 1896. These patients
are in excellent condition, well nourished, and
contented.

My own experience, though very large, does not
show results so good as that of Kocher. My work was
done in St. Louis, Missouri, and in private practice to
a large extent, and the cases were not in as good condi-
tion as those of Kocher, whose work was mostly done
in a public hospital, in Bern, on patients who were
under good control. Out of twenty-one resections I
have only two deaths following immediately upon the
operation. All the others survived the operation, and
I may say all of them were benefited to some extent, and
one lives to-day from whom I removed a pyloric cancer
as large as a child's head seven years and a half ago.
The man is now sixty years of age and works a forty-acre
farm. Thirteen died within one year from a return of
the cancer and seven lived from a year and a half to
four years. (Of these, two are still in good health.)

From Kocher's statistics, and also from many oth-
ers, it is clear that the time has come in which we may
speak of permanent cures in cases of cancer of the
stomach, the most dreadful of all the forms of can-
cer that we know of, because if left alone in many
cases the patient is condemned to actual and hope-
less starvation. A decided improvement in the mor-
tality is also noticeable. Krönlein lost three out of
his first four operations, and only lost two out of the
last twenty. The same can be said of almost every
surgeon who has kept up the good work of trying to
cure cancer of the stomach in the face of an early ap-
palling mortality. If the general practitioner will send
his cases for early operation we may expect a mortality
of less than ten per cent. If, however, the extreme
skepticism about the success of operations prevails, and
the unfortunate patient seeks surgical relief after ca-
chexia has begun, we will have a high mortality and bad
results.

I have made it a rule in recent years not to attempt
a resection on weak patients, and limit my operation to
a relief of the stenosis by a gastro-enterostomy. In pa-
tients who are comparatively strong, and in whom there
is a localized and movable tumor, the radical operation
is indicated.

Since Schlatter, of Zurich, successfully performed
his total excision of the stomach, a number of these
operations have been done by others, but the results
prove that suitable cases for this operation are prob-
ably not common.

In conclusion, let me say to you that if as a result

of this address some cancer cases shall be driven to seek
relief by the only rational means we have to offer—
namely, by careful and complete surgical eradication—
I shall feel that my effort has been rewarded. Should
a few cases be radically cured and twice as many killed
by the operation, all will have derived more benefit than
if none had been operated on; for those who are killed
by the operation are saved from a most horrible slow
death. I am perfectly conscious that in thus strongly
advocating operation not only in simple but in advanced
cases of cancer I shall meet with some adverse criticism.
I am consoled by the thought that a valuable victory can
not be gained without first having a fight.

NOTES ON
URETHRAL CATHETERISM, CATHETERS, AND BOUGIES.

By J. W. S. Gouley, M. D.

(Concluded from page 666.)

30. Bougie, candela, cadelula, candioletta, virga

cerea are the names by which this tool has long been

known among the Latin nations. The term bougie is

one of the many examples of the perversion of words

and of the arbitrary meaning given them. Thus Bij-
yah, Bougeiah, Bugia, Bougie are among the modern

varieties of the name substituted for that of the Roman
colony of Saldaa. The Roman town was built upon the
deelivity of a mountain at the mouth of the Aduse
River one hundred and twenty-two miles east of Al-
giers. The present town lies upon the ruins of the
ancient settlement, which was invaded by the Vandals
in the fifth century, but which, from the year 708, was
under the domination of Arab conquerors, and then fol-

owed the fortunes of divers Berber dynasties; owing
its name Bijiyah to the Berber tribe of Bedjain (1068)

En-Nacer, the founder of the new town, having tried in

vain to give it his name. The place was named Bugia,*

probably by the Spanish, who took it in 1509, and

retained possession until 1555. It afterward passed into

the dominion of the Dey of Algiers, and, in 1833, was

occupied by the French, who call it Bougie. For many
centuries it had been a thriving seaport, at one time a
safe harbor for Algerine pirates (hence its invasion by
the Spaniards) and a trading station for metals, oil,
and wax, brought from the interior by the Kabyles.
The wax and candles of the town of Bougie were much
valued in the markets of southern Europe,† particu-

* The writer's attention was directed by a client to the Italian word
bugia, which means a lie, with the suggestion that it might be allied to
the medical term, but he has since ascertained that bugia, lie, has noth-
ing whatever to do with the town of Bugia, but is related to the Pro-
vençal banza, deceit, the verb being benvanz; to the old French baver,
to cheat, baster, fraud; and this to the old German bösen, badness, roguey.
† The Venetians, who were the first to make known wax candles in
Europe, had learned their use from the Arabs.
larly in those of France. The populace and traders, ever prone to abbreviate regardless of propriety, substituted for Bougie-wax candles, wax bougies, then suppressing the wax and naming all kinds of candles bougies, and finally giving the name of bougies to all cylindrical urethral instruments, whether of wax or of other substances. The word has been so long used in medical language that it would now be unwise to substitute any new name for bougie, inexpressive as it is of the uses for which it is intended. This term bougie will therefore continue to be employed to signify an instrument for exploring or for dilating some of the excretory ducts of the human body until the right term is coined by properly constituted authority.

31. The time of the invention of urethral bougies can scarcely be fixed with certainty. The following are the only sources of information which have been accessible to the writer. Andrea Lacuna (1551), a Spanish physician, thought that bougies were invented by Philippe, an itinerant Portuguese charlatan, who communicated to him his mode of producing them. They were made of wax, with a central longitudinal wick, and were then introduced as far as the bladder for the diagnosis and treatment of "caruncles or carbosities." The spot in the bougie where "a caruncle or a carbosity" was supposed to have left an impression was further excavated, or the calibre of the bougie was lessened by pressure and rotation between two hard bodies, and this space filled with an unguent in which entered acetate of copper, yellow sulphide of mercury, vitriol, alum, vinegar, lathure, etc. The bougie, thus prepared, was introduced into the urethra so that the medicated part acted upon the "caruncle." Amatus Lusitanus (1554), a Portuguese physician, said it was he who, during his stay at Lisbon, had taught Philippe the manufacture and use of these bougies, and that he, Amatus, was indebted to Professor Aldereto, a physician, of Salamanca, for his knowledge of the bougies. Alphonso Ferri, of Naples, asserted, in a work printed in 1553, that he had used the unguent and bougies as early as 1548. However, the use of this unguent was described in the sixth century by Alexander of Tralles. Ferri had used for urethral exploration stems of malva, parsley, and fennel; also flexible leaden cylinders, which he sometimes introduced as far as the bladder. These leaden cylinders were by others rubbed with mercury, which rendered them so brittle that the process was soon abandoned. Petronius, Paré, and many other physicians of the time made use of the unguent, more or less modified in its component elements, and of the several bougies, medicating them with the object of destroying the supposed "carneules and carbosities." Giannatus, an Italian charlatan, treated Charles IX for pretended "carneules," employing bougies medicated with an "escharotic ointment." In speaking of tin bougies, Jourdan said that they were generally cylindrical, but that Francisco Diaz suggested for them a triangu-

lar form and pointed (conical or wedge-shaped(?)), in order that they might more easily pass beyond the "carneules." Here, then, is an early link in the evolution of conical bougies. Soon after the time of Diaz whalebone bougies were used, but as soon given up. Daran* revived in France the use of medicated bougies and published many "cures," but some of his contemporaries, better instructed, soon showed that his good results were due to the mechanical dilatation effected by the bougies rather than to any medicinal action of the substances which entered into their composition.† It was not until the time of Thedn and Bernard (in the latter part of the eighteenth century) that elastic bougies were made for the purpose of dilating strictures, and these bougies have since been undergoing improvement in construction and form from the hollow cylinder to the solid, from the straight to the elbowed, and from the conical to the olive-tipped.

32. Whalebone bougies were used in France early in this century and also in the United States. Dr. H. G. Jameson (Medical Recorder, 1827) spoke well of the utility of whalebone bougies of "the size of a small knitting needle" in the treatment of urethral strictures. Whalebone bougies are of two kinds—those with olivary point and elbowed, about one millimetre in diameter, to serve as conductors for larger instruments, and those for the dilatation of narrow strictures. The second, also elbowed and olive-pointed, are not over one millimetre in diameter for the first three inches, thence increasing gradually in diameter, so that at five inches they are equal to Nos. 2, 3, 4, 5, 6, and 7, English scale, the set comprising six bougies, as indicated by these numbers. All whalebone bougies require to be thinly coated with carbolized vaseline and preserved in metal tubes; otherwise they become dry and brittle and are soon destroyed by parasites. It does not seem necessary to do more than make bare mention of some of the many kinds of bougies used from the time of Bernard—as those made of catgut, recommended by Dr. Dease, of Dublin, in the last century; of gentian root, of slippery elm bark, of prepared sponge (Aliquè); of the cadalie bougies of Lioulit (1828); of the air dilators of Ducamp and Arnott; of the elbowed bougies of Benjamin Bell (1793) and of Whatley (1806); of Ducamp's wax-tipped bougies for taking impressions of strictures, and of Bigelow's gutta-percha bougies for the same purpose; of Olili's urethral stenosimeter; of the metallic "ball probes" of Sir Charles Bell for the exploration of strictures; of Leroy d'Étiolles's soft bou-

* In an assembly of ladies and gentlemen, accidental mention was made of Daran, whose name was constantly before the people, for he did not hide his light under a bushel. One of the ladies, hearing it, asked, "Quel est donc ce Monsieur Daran?" A wit quickly replied, "C'est un homme qui prend vos vessies pour des lanternes."
Of the divers sorts of urethral and urethro-vesical catheterism, only the exploring, dilating, evacuating, and irrigating need be examined on this occasion. The importance of the subject warrants the repetition that catheterism demands the utmost deliberation and gentleness, the greatest steadiness and lightness of digits, the clearest conception of the anatomy of the parts, and the most precise concert of action of mind, eye, and hand. The honeyed utterance of Civiale—doucement et lentement, gently and slowly—in the performance of catheterism, whenever borne in mind, has often served to prevent serious injury, which rough manipulation and precipitate action so frequently inflict upon the urethral canal. Catheterism for urethral or urethro-vesical exploration, as well as for dilatation and evacuation, is ordinarily performed during dorsal decubitus of the patient, because the standing posture favors syncope, and because recumbency of the patient is much more convenient to the operator, seated, as he is, by the sufferer’s left side for urethral and by his right for vesical exploration.

Urethral exploration for the detection of a foreign body or of a suspected calculus impacted in the canal is made with a metallic instrument, serving at the same time for the extraction of either; the most commonly used being the slender alligator-jawed forceps, and the urethral lithotrite (of which there are several kinds) in the case of a calculus too large to be removed in its entirety. In the case of oblong foreign bodies in the bladder the explorer should also be the extractor. The writer once removed entire a cylindrically fashioned piece of raw potato nearly four inches long, which the patient had introduced into his urethra, and which was swallowed by the bladder. The extraction was accomplished by means of a rectangular metallic catheter with forceps extremity. Lithotrites generally answer the purpose of searching for and removing pieces of soft catheters from the bladder, while special tools are employed in the extraction of parts of metallic catheters and other hard, oblong, or cylindrical objects.

Urethral exploration of the prostate is made with the writer’s cysto-pyrometer or with Mercier’s rectangular solid sound, which will do also for exploration of the bladder walls; while the detection of stone may be achieved with Mercier’s rectangular hollow search or with Langlebert’s lithophone.

Exploration of the urethra for stricture is best made with the soft, flexible, acorn-tipped web bougie, the penis being held between the middle and ring fingers, palm up, while the thumb and index retract the prepulse and part the lips of the meatus. A previously lubricated bougie, whose acorn-shaped tip is as large as the urethral orifice will admit without being overstretched, is then slowly inserted and gently pushed onward until it reaches an impediment. The length of the bougie being known, measurement of the distal or extra-urethral part from the meatus will give approximately the situation of the stricture. For practical purposes it is essential only to know if the stricture be in the phallic, scrotal, or perineal region of the urethra. A smaller bougie, which just passes the stricture, indicates its calibre, and, by leaving it in that position for a few seconds and slowly extracting it until the base of the acorn reaches the vesical end of the obstruction, the length of the stricture is easily ascertained by proper measurement of the shaft of the instrument that is out of the canal. A second or a third stricture may be diagnosed by means of this or perhaps of smaller acorn-tipped bougies. Metallic bulbous bougies can not be used with the same delicacy and precision as the soft instruments, and their rigidity is often a source of no little danger.

Dilating catheterism, whose purpose is the restoration of the urethra’s normal calibre, is ordinarily effected, in the case of narrow strictures free from complications, by the momentary insertion of flexible web bougies every second or third day, increasing the sizes until No. 10 or 12 of the English scale shall have been reached. After this, conical steel sounds may be used, not oftener, however, than once a week, and seldom exceeding No. 15, English scale. Those patients who live far away from the reach of their surgeon should not be intrusted to pass steel sounds, as they are not likely to acquire the needed skill, and are almost certain to do serious mischief to their urethra. They should therefore be taught the use of very soft, olive-tipped web bougies not larger in the shaft than No. 13.

To refrain from making a false route or otherwise injuring the parts during the passage of a metallic sound or catheter in the urethra, the incursions of this canal should be kept constantly in mind, the first point of danger being at the peno-scrotal and the second at the bulbo-membranous junction; and to guard against these disastrous accidents the operator should direct the extremity of the sound or catheter downward toward the perineum (after the manner of the ancient tour de maitre), so as to prevent impingement at the first-named point of danger. Having passed this point, he makes with the handle of the sound a slow and deliberate sweep upward and to the left, which brings its extremity into the proper position; then very slowly depressing the handle between the patient’s thighs at the same moment that the end of the sound is tilted up as it arrives at the second point of danger—i.e., the bulbo-membranous junction—it slips easily into the bladder.

The catheterism of narrow, eccentric, tortuous urethral strictures, especially those complicated by false routes and distressing retention of urine, is one of the most delicate, difficult, and often perplexing of surgical procedures, requiring for its safe and successful execution mature experience, skill of the highest order, slow
and gentle manipulation, imperturbable coolness, exhaustless patience, and unrelaxing persistence. The first step in this kind of catheterism is to lubricate the urethra by filling it with warm olive oil or with petroleum; the next is to pass an elbowed capillary whalebone bougie with which to explore the region of the stricture until its lumen is found, when the bougie will enter the narrowed canal; but even after it has passed this point its extremity often glides into the mouth of an enlarged lacuna or of one of the ejaculatory ducts, from which it must be disengaged, slightly rotated, and pushed onward, when at length it will reach the bladder. This process sometimes occupies half an hour or even longer. Dilatation may then be made with a small tunneled conical steel sound (the whalebone bougie being the conductor for the sound), as described by the writer in earlier papers. The success of these steps generally insures the good effects of subsequent dilating catheterism, and is almost always prophylactic of cutting operations. When it happens that dilatation can not be carried beyond No. 2 or 3, then a catheter No. 2 or 3 is introduced and retained twenty-four or even forty-eight hours, during which time the urine constantly trickles away, to the relief of the bladder, and this "continuous dilatation" facilitates the passage of larger bougies, so that in a few days dilating catheterism in higher numbers is performed with comparative ease. The foregoing is assuredly the most optimistic view of catheterism in difficult cases. How often this catheterism is disappointing and unsuccessful, particularly when a false route is to be eluded, those who have had much experience will testify. The operators who "always succeed" are to be congratulated if they always succeed! When, after repeated patient trials by an expert, the bladder can not be entered, the only resort is, of course, external perineal division of the stricture after capillary hypogastric puncture of the bladder and aspiration of the urine to afford temporary relief of the distended bladder in case of great urgency.

Unduly frequent and excessive dilating catheterism is undesirable, injudicious, irrational, and harmful. The consequent bruising of the mucous membrane excites a subacute urethritis whose exudate in the underlying connective tissue undergoes sclerous degeneration, ending in loss of suppleness and permanent contracture of the whole canal.

35. Evacuating catheterism is used to rid the bladder of calculus detritus after lithotripsy; to aspirate clots of blood or slimy urine from the bladder; to relieve retention of urine due to urethral stricture or to prostatic obstruction, and to draw off urine daily in cases of its stagnation from urethral bladder or urethral impedi-

For aspiration of calculus detritus after lithotripsy and of blood clots from profuse cystorrhagia, as well as excessively thick, purulent, slimy urine, the large metallic catheters adapted to Bigelow's apparatus answer the purpose admirably. In their introduction the same care and deliberation should be observed as in the passage of other metallic catheters.

In urethro-vesical catheterism for retention of urine due to a stricture, it is generally necessary to begin by dilating the stricture rapidly, even to the extent of its divulsion, until a No. 4 or 5 tunneled sound, with the aid of its whalebone conductor, can be introduced; then to substitute a tunneled metallic catheter of the same size. When, however, it is possible to carry dilatation to higher numbers, say 9 or 10, then a No. 8 web catheter is inserted and some of the urine allowed to escape slowly. Under no circumstances should a distended bladder be emptied precipitately, for reasons that are too well known to require rehearsal. The same and even greater precautions are to be taken in the case of urinary retention due to prostatic obstruction. Physicians have often asked, What is the best catheter for such cases? The answer to the query has invariably been that any one catheter can not answer in all cases. They should be provided with catheters for the different forms of obstruction. For example, in ordinary cases of supramontanal enlargement of the prostate, the curved silk-web catheter is sufficient, and also the velvet-eyed India-rubber catheter; but in cases of intra-urethral prostatic growths, of unilateral enlargement, of unequal enlargement of both lobes, and of urethro-vesical barriers, Mercier's elbowed catheter is required, and sometimes the crutched catheter; while in cases of enlargement of the superior isthmus with supramontanal increase, causing great depression of the prostatic sinus, Mercier's double-elbowed catheter is the most useful.

36. Respecting the size of the catheters, the question, Should they be small or large? is very commonly asked. The answer is that they should be neither large nor small, but adapted to the particular urethra to be catheterized. A catheter of full size for a urethra under the average is too small for a urethra of extraordinary large calibre. A No. 14 (English) is small for the latter, and entirely too large for the former, to which a No. 7 (English) is likely to be much more suitable. These, however, are extreme cases. The most convenient size to the physician and to the patient, one that strikes a fair average, is No. 9 (English). It is rare to find urethra that will not admit a No. 9, particularly in cases of stagnation of urine from prostatic obstruction, stricture being excluded. Many patients who are obliged to catheterize themselves labor under the delusion that small catheters are safest and give least pain. To the use of small catheters may be ascribed the majority of prostatic false routes and the frequent attacks of urethritis and orchitis from which auto-catheterists suffer. The best-sized and safest catheter for each individual is the catheter that moderately fills and therefore does not
stretch the urethra. Such an instrument gives less 
pain than the too large or the too small catheter.

37. The India-rubber "velvet-eyed" catheter is or-
dinarily the safest for general use by the inexperienced 
and for auto-catheterism, but its long-continued use 
upon or by the same patient is not advisable. The 
security felt by the patient is often a source of danger, 
for he is soon heedless of the precautions advised by 
the physician and suffers much in consequence. How 
much more frequently the physician is called upon to 
remove from the bladder fragments of or entire India-
rubber catheters than of other firmer instruments!

But, aside from these accidents, the urethra is often 
greatly irritated by the rubber catheter, not on account 
of this material itself, but of the carelessness, boldness, 
and undue frequency of its use, which come of its easy 
introduction. Painstaking, prudent, and intelligent 
patients soon acquire sufficient skill in the use of any of 
the several pliable catheters and learn to keep them in 
good order.

38. It frequently happens that the physician is 
called upon to relieve patients from retention of urine 
when ordinary catheterism is impossible by reason of 
false passages in the prostatic region. In such cases 
the common practice has been to make a suprapubic 
puncture with an ordinary trocar and insert a catheter 
or a silver tube, to be opened as often as necessary for 
urination. Thirty years ago capillary puncture with 
aspiration was introduced to the profession by Dieula-
foy, and this novelty soon became the fashion. Many 
successful cases were reported, and capillary puncture 
with pneumatic aspiration was to be the operation in 
retention of urine. Although at first no reference was 
made to accidents, in a few years the vogue of the process 
was on the wane; now it is employed with more discrimi-
nation, and only to relieve extreme distention once or 
twice, and not ten, twenty, or thirty consecutive times in 
the same case. Capillary puncture with pneumatic aspi-
ration is an excellent resource in medicine and surgery; 
it can not be too highly praised, but its abuse should be 
loudly decried.

39. No kind of puncture of the bladder ever can 
remove a false route, and capillary puncture is not so 
safe a process as was at first believed. The conse-
quences of the escape of a few drops of urine in the 
prevesical connective tissue have been so disastrous in 
a number of cases as to deter cautious physicians from 
employing this method of relief except under circum-
stances of the greatest urgency; but there is an equally 
forcible objection to its general employment—to wit, a 
simple, safe, and efficient procedure has existed for the 
past fifty years. Why it has not been more frequently 
employed is not apparent, but it is nevertheless valu-
able. In the year 1850 Dr. Mercier published in the 
Union médicale an account of his invaginated catheter 
for use in cases of prostatic false routes. Descriptions 
and drawings of the instruments have appeared in dif-
ferent books and periodicals, but little heed seems to 
have been otherwise taken of this precious device. It 
may be fairly stated that in ninety-five per cent. of 
cases of prostatic false routes the invaginated catheter 
can be successfully applied. The instrument as now 
made consists of two catheters—one metallic, the other 
non-metallic. The first or female part is a thin-walled 
No. 10 (English) silver catheter, eleven inches long, 
very slightly curved, and having in its concavity, about 
half an inch from the point, an oval eye five eighths of 
an inch in length and three sixteenths in breadth. From 
the vesical extremity of the eye is an inclined plane, 
which is lost in the floor of the opening at the distance 
of a quarter of an inch, serving to tilt up the point of 
the male part. This male part is a flexible but firm 
"gum" catheter (No. 7, English), eighteen inches long, 
fitting loosely in the lumen of the female part, and 
having a single eye an eighth of an inch from its point.
The way to use the invaginated catheter is to introduce 
the male into the female part as far as the eye of the 
latter, then to pass the instrument as far as the obstacle 
and engage the point of the metallic part in the false 
rute, and finally project the male part, which will over-
ride the false route thus blocked and enter the bladder.
If no urine should flow, it would be owing to closure 
of the eye of the male part by a blood clot, which might 
be forced out by the injection of a little water through 
the male catheter. The female part can then be with-
drawn and the male left in as long as may be required; 
this is the reason for the increased length of the male 
part.

40. When a patient has long used the catheter for 
relief of his bladder, and the urethra has suffered from 
the consequent irritation followed by urethritis with 
spasmodic contracture, which renders catheterism pain-
ful and difficult, it becomes necessary for the surgeon 
to irrigate the canal at least once each day, and to 
dilate it with steel sounds every three or four days for 
two or three weeks, when daily evacuating catheterism 
is again easy. This process should be repeated every 
three months or thereabout. An evil which should be 
avoided is the too frequent use of the evacuating cath-
eter by the patient, who, if not cautioned, passes the 
instrument every hour or two if he happen to suffer 
much from vesical spasm. This may be obviated by the 
administration of the one two-hundredth of a grain of 
yoscamine three, or at most four, times daily, but for 
not more than four days, as the drug can not generally be 
tolerated longer, and its use should not be resumed until 
three or four days thereafter. The effect of the hyos-
camline is to abolish vesical spasm in the majority of 
cases. It is rarely necessary for the well-trained patient 
to catheterize himself more than six times in the twen-
ty-four hours in case of prostatic obstruction to sponta-
aneous urination.

41. The frequent evacuative catheterism necessi-
tated by prostatic obstruction causes a subacute ure-
thritis, which demands daily irrigation of the urethra, whose mucous membrane sometimes becomes so edematous as to render catheterism difficult and even dangerous. In such cases, the careful introduction of flexible web bongies, or of steel sounds, of increasing size to No. 15 (English), every second or third day for two or three weeks, relieves the swollen mucous membrane, restores the suppleness of the canal, and facilitates the evacuative catheterism. Another ill effect of this indispensible frequent catheterism is acute oritis, due generally to the use of unclean and fissured instruments. This occurs, in some patients, as often as every three or four months, first on one side, then on the other, seldom on both sides at the same time. After several attacks, the orititis becomes chronic, and sometimes small purulent foci are formed in the substance of the testes. These abscesses generally open spontaneously and are rarely incised, the patients objecting until they are taught by experience that early incision is wise and proper. Finally, the spermatic canals are occluded, and the genitic function is at an end.

42. In catheterism for vesical irrigation and dilatation, rigid, especially metallic, catheters should not be employed. The best and safest are those that easily enter the bladder without causing undue irritation, such as the several forms of web catheters, and the India-rubber catheter without eye, but open at the well-rounded, smooth vesical end. The double-current catheter should be abolished, if only for the reason that it does not accomplish the desired object of allowing enough of the injected material to accumulate for proper irrigation and for even slightly distending the viscus, since the stream enters through one eye of the instrument and immediately passes out of the other, and not more than a square inch of the mucous membrane is affected by the fluid. Should it be said that the outlet can be closed for a moment to regulate distention, the reply would be that this closure converts it into a single-current catheter, by which irritation and distention are attained. Why not, then, use the single-current catheter, which is simpler, less bulky, and not so costly? The double-current catheter is, to say the least, an unnecessary tool. The substance injected is, of course, that which is indicated for the morbid state to be treated. The injector may be the fountain or the pear-shaped India-rubber bag. Irrigations for cleansing the bladder may be made by the patient with the aid of the fountain syringe, but when needed for gradual dilatation of the contracted bladder these irrigations should be made by the surgeon, who will generally find the India-rubber pear the better instrument, for with it he can, by pressure with the hand, quickly determine the degree of justifiable dilatation.

The St. Louis Medical Society.—At the last regular meeting, on Saturday evening, the 4th inst., Dr. William Porter presented a paper for discussion, entitled Abscess of the Lung.

BRAIN FATIGUE.

By R. Ellis, A. B., M. D., Utica, N. Y.

While reading the diary of Sir Walter Scott recently, I was specially interested in a passage describing one of his nervous conditions, since a patient presented himself at my office at this time, complaining of similar sensations, which he described with considerable difficulty.

As I believe such a mental condition is seldom if ever described in medical literature, I will first quote from the diary and then describe the sensations of my patient, which I think agree with the description given by Scott.

All know the tremendous tension that Scott was under; all know the result of this tension was the earning of six hundred thousand dollars—the amount of his indebtedness. A few quotations will enable us to appreciate the one ruling thought of Scott's brain—a thought that must have kept his brain "congested" for several years.

"I will die a free man if hard work will do it—"  
"The best o't—the worst o't  
Is only just to die,  
and die I think I shall, though I am not such a coward as mortem conscire me ipso, but I gin to grow weary of the sun, and when the plant no longer receives nourishment from light and air, there is a speedy prospect of its withering."

"I have been stove up all day, and could not gather my spirits—this is nonsense and contrary to my system, which is of the Stoic school and pretty well maintained. . . . Once drawn upon the beach, I would soon break up, so I continue my exercise."

"The point in this world is to do what we ought, and bear what we must."

"My nerves weak—the beauty of the evening—the sighing of the summer breeze, brings the tears, but I must harden myself—it is not the law we live on."

"If I were capable, in a moment of weakness, of doing anything short of what my honor demanded, I would die the death of a poisoned rat in a hole, out of a mere sense of my own degradation."

Appreciating the fine calibre of the man, as well as the tension he was under, from these quotations, we are prepared for the following nervous condition:

"A kind of a cloud of stupidity hangs about me as if all were unreal that men seem to be doing and talking about."

"A day of hard work, being, I think, eight pages before nine. I can not, I am sure, tell if this is worth marking down, that yesterday at dinner time, I was strangely haunted by what I call the sense of preexistence, videlicet: a confused idea that nothing passed was said for the first time; that the same topics had been discussed, and the same persons had stated the
same opinions on the same subjects. It is true there might have been some ground for recollections, considering that three at least of the company were old friends, but the sensation was so strong as to resemble what is called a mirage in the desert, or a caleenure on board ship, when lakes are seen in the desert, and silvan landscape in the sea. It was very distressing yesterday, and brought to my mind the fancies of Bishop Berkeley about an ideal world.

"There was a vile sense of want of reality in all I did and said. It made me gloomy and out of spirits, though I flatter myself it was not observed.

"The bodily feeling which most resembles this unpleasing hallucination is the giddy state which follows profuse bleeding, when one feels as if walking on feather beds and could not find a secure footing. I think the stomach has something to do with it. I drank several glasses of wine, but this only augmented the disorder. I did not find the in vino veritas of the philosophers. Something of this insane feeling remains to-day, but a trifle only."

My patient is a sensitive man of sixty, who has been carrying a load for a good many years—a sensitive man who all his life has been struggling up the hills of life which he expected to fly to in the dreams of youthful enthusiasm; he is a man of fine calibre, and should be a man of wealth, for an oversensitive man of fine calibre is not at his best but at his worst when the day's life means a day's struggle for mere existence.

Such a struggle is best maintained by a man of really coarse calibre who is skilled at acting the part of a gentleman, and knows how by polished manners to force from environment the best possible.

My patient was seriously handicapped by his sensitive temperament, so he carried his load under great tension, and silently endured the "whips and scorns of time."

He tells me that six months before consulting me, after a trying week, he noticed a dizziness and an uncomfortable sensation in the head, which increased for several days, until one morning, while writing a letter, he found he could not remember the name of his little town, though he had lived there some long time. Being an intelligent man, he readily diagnosticated this symptom as brain fatigue, and, resting from his work a few days, found complete relief.

Such an experience, however, aroused his curiosity, and made him an observing student of his mental condition.

Six months after this brain fatigue, the tension of climbing up the hills of life with difficulty became severe and interesting symptoms followed—a feeling of mental weariness after a few hours of brain work; then a tendency to stagger while walking, which seemed to increase if noticed carefully. Though he knew he was "all right," he felt he was "almost all wrong"; everything said and done by others seemed "queer"; conversation was exceedingly disagreeable and flat, especially since those conversed with seemed to be in a "haze."

No one noticed the condition of my patient, especially since he knew he was all right in the eyes of his friends, because he knew his symptoms were purely subjective, and not observed by his friends. He acted so naturally that the only flaw his friends could find in him was an "unnatural seriousness" which he avoided "by trying hard to be cheerful."

He knew his symptoms were due to "nervousness and mental fatigue," so he tried to control as well as to study himself.

He tells me his life during this time was and always has been regular in every way; that he ate and slept well and was well in every way save for these symptoms. After he had been under a severe mental strain for a few weeks, his symptoms, which had decreased in severity, increased until he became a little alarmed, as "everything seemed so queer and bqzy."

He would think of or hear of some trilling incident, and at once his mind would say, "I've heard that before," and then would follow a mental hunt for the time and place; this "hunt" would last possibly fifteen minutes and end with little satisfaction, only to be followed by "another hunt. This seeking for the "previous time and place" seemed to give a mental sensation "vibrating" in character, and not as disagreeable as unsatisfactory. This mental condition would last possibly three or four hours in its intensity, and then slowly pass away. During this time, satisfactory mental application was not possible, so the patient, realizing rest was his best medicine, decided he would first consult me and then rest in the mountains.

I found him a bright, active gentleman in literary life, with too much work amid too many cares and responsibilities—a man of too fine a calibre for some of the rough-and-tumble contests he had been engaged in. He gave a good, clean history in every respect, and correctly diagnosticated his trouble as "brain fatigue," due to too much mental work and worry.

A vacation of a few weeks completely restored his nervous tone and he returned well. I believe his mental condition to have been as Scott's was—a condition produced by too much work and worry.

I have written this brief paper because I do not remember to have read anywhere of that mental condition which Scott calls "a strange sense of preexistence."

---

THE TREATMENT OF EPIDIDYMITIS.

By ROBERT C. KENNER, A. M., M. D.,
LOUISVILLE, KY.

If we would always have our patients suffering with gonorrhoea wear a suspensory bandage from the first appearance of the disease, it is highly probable that the supervision of epididymitis would be a much less common circumstance.
A suspensory bandage may or may not be of value to the patient. If we simply order these patients to buy a suspensory bandage and wear it, we shall fail altogether to get any good from it. We should get a suspensory, and I am generally indifferent to the kind used, and see that it actually supports the testes. If this is not done the suspensory is not capable of rendering our patient any good service. If, when the suspensory is applied, we find the testes not supported, we should put some cotton or a handkerchief there to hold the testes up. We should also tell the patient to look after this matter at night, and, if in the recumbent posture the testes are not supported, to have a pillow so placed as to afford the support desired.

The treatment of epididymitis can best be considered under two heads: First, measures applicable in the stage of acute inflammation. Second, remedies which hasten the removal of the inflammatory deposit.

Some cases of epididymitis are essentially mild in character and will call for no other remedial measures than having our patient go to bed and have the testes well supported. In these cases, however, the diet should be light, and the recumbent posture must be maintained so far as possible.

The pain that occurs in these cases of epididymitis that do not assume a mild form, however, is something equaled in few of the minor affections.

As a means of relieving the pain I have relied to the largest extent on the application of tobacco leaves wet in water as hot as can be borne and applied directly to the scrotum. Rarely I have found cases where tobacco caused nausea, and in one patient the tobacco irritated the skin. When tobacco does not have a happy effect I trust to a flaxseed-meal poultice, to which laudanum has been added in liberal quantities.

This has not failed to act well, but it is not so efficacious in the relief of pain as the tobacco.

I have the leaves of tobacco applied fresh when they get cold. My experience with cold applications has been unsatisfactory, and it is common to find patients objecting to their employment. A study of my cases, and those of others, has not convinced me that cold applications are capable of rendering us valuable service.

Frequently we shall find these patients with considerable fever. In these cases we may safely resort to any coal-tar antipyretic. They often act in a most happy manner.

Other indications for treatment may arise which will have to be met on general principles not necessary to be defined here.

In carrying out the second indication—that of administering remedies which will hasten resolution—we find that one remedy has been recommended as almost a specific—that drug is pulsatilla. In quite an extensive experience, I have not found this agent capable either of cutting short the period of acute inflammation or of exerting any appreciable effect in removing the inflammatory products.

Strapping has, beyond any doubt, brought me results which were satisfactory; but patients generally dislike this means, and it is far from being a superior measure.

The painting of the scrotum with a solution of nitrate of silver has brought about good results in a limited number of cases, yet this measure is not now relied upon extensively by the profession.

I have obtained better results from the employment of iodine vasogen than by any other agent which I have yet employed. This agent I have rubbed into the scrotum every three or four hours. It has hastened resolution and brought about a reduction of the swelling more speedily than any other means at my command. My patients treated with this agent have recovered in an average of five days. I have notes of fifteen cases treated with it.

Its use was begun in these cases after the subsidence of the symptoms of acute inflammation, and when the swelling was at its maximum. I have not employed the remedy in any case of chronic testicular induration.

The agent has not proved an irritant, as is frequently the case when tincture of iodine is employed. In these cases no internal remedy has been exhibited except when the patient had some coexisting disease, or where great pain, fever, or some other symptom attained to such importance as to make that course advisable.

Time and consideration for space will permit me to give even in outline only a few of these fifteen tabulated cases:

Mr.——, aged twenty-three years. This young man, a medical student, sent for me on March 1st. I found him in the throes of a most painful epididymitis. I used the tobacco leaves wet in water as hot as he could bear, and his testes were held up by a properly adjusted suspensory. He was kept in bed and had a low diet. At my visit on the third day the tenderness and pain were nearly gone. I now had him leave off the tobacco leaves and began with the employment of iodine vasogen. This was rubbed on every three hours. It produced no discomfort, and the reduction of the swelling was manifest eighteen hours later, and proceeded without interruption to complete resolution five days later.

Mr.——, aged thirty years. This patient had treated the present attack of gonorrhoea with contempt. He was now seized with epididymitis. I saw him after he had considerable swelling and he was now suffering intensely. Tobacco acted as an irritant in this case, so I resorted to flaxseed poultices with laudanum. They were kept warm—in fact, hot as the patient could bear. The pain subsided, and he was treated as was the other patient, with iodine vasogen, rubbed in every three hours. He got along well, and was discharged four days after the commencement of the iodine vasogen systematically.

Mr.——, aged twenty-nine years. This patient was seen after the period of acute inflammation had subsided. The right testicle was swollen to a larger size.
THERAPEUTICAL NOTES.

Ichthyol in Renal Tuberculosis.—Goldberg (Berliner klinische Wochenschrift; Journal of the American Medical Association, October 21st) refers to Palet’s statistics and shows that of a hundred and thirty-six cases of nephrectomy done for renal tuberculosis, fifty-one, that is forty per cent., died, and that only one third of those operated on lived over one year. This result was due to infection of other organs. He recommends ichthyol internally.

R Ichthyol. sulfo-ammoniac, 1 a. 5v.
Aque destillate, M.

From ten to seventy drops to be taken in water three to five times a day after eating. The larger the dose the sooner the curative action is manifested. Besides causing a general improvement, the author has found that the local action was good—the haemorrhages ceased and the suppuration diminished, as did also the tenesmus and pain. It may be given for years.

Electricity in Sciatica.—Dr. James Taylor (Clinical Journal, October 11th) reminds us of the well-known but too much ignored fact that electricity is very useful in sciatica; it is useful, first, in relieving the pain, which is often severe, and, in the second place, it is useful in stimulating muscles which have become wasted, and thus aiding their growth. In sciatica itself the best current to use is, he says, the constant current, and it is best used by getting the patient to lie prone with one of the flat conductors over the sciatic area, the other pole being stroked over the distribution of the nerve. He has known very great benefit, and, indeed, practically complete relief, afforded in sciatica from comparatively few applications of the battery.

For Sycosis.—Riforma medica for September 18th gives the following:
R Naphthol ...... from 75 to 150 grains;
Green soap,
Prepared chalk, 1 of each ..... 375 “
Sulphur,
Lanolin,
M.

For local application.

The Place of Digitalis in Heart Disease.—Dr. W. H. Washburn (Merck’s Archives, October) concludes a paper as follows: Digitalis is seldom required in chronic valvular disease during the period of complete compensation. When the stage of broken compensation is present it is urgently demanded, in all forms and combinations of lesions, in proportion to the degree of cardiac weakening. When given in doses of more than two or three grains of the powdered leaves, or the equivalent thereof, in the twenty-four hours, symptoms of saturation are to be anxiously watched for when from thirty to forty grains have been administered, and the drug should be discontinued for a few days or the dose reduced as soon as they appear. The drug is thereafter to be continued in tonic doses. Finally, tonic doses of digitalis are always useful in the treatment of weak, neurotic hearts.

For Impetigo.—Riforma medica for September 18th ascribes the following to Brandis:
R Salicylic acid .......... 30 grains;
Lanolin .......... 750 “
Oxide of zinc, 1 of each ..... 360 “
Starch, M.

For local application.

Ichthyol in Whooping-cough.—Dr. J. Francis Sonter (Australasian Medical Gazette, September 20th) records the satisfactory results obtained by him with pills of ichthyol in whooping-cough. He put four of his own children, varying in age from two years and six months to eight years, on one grain (increased in a few days to two, then to three and four grains) every four hours. Marked improvement ensued from the first, and Dr. Sonter tried the remedy with equally favorable results in ten other cases. He saw no unpleasant effects.

For Coryza.—Riforma medica for July 7th ascribes the following to Hallopeau:
R Powdered menthol ...... 3 1/2 grains;
Powdered betol .......... 3 1/2 “
Cocaine .......... 1/3 “
Powdered roasted coffee ...... 60 “
M.

To be used as a snuff.

Potassium Permanganate Enemata in the Treatment of Dysentery.—Dr. Gastinel (Archives de médecine navale, 1899, No. 8; Klinisch-therapeutische Wochen-schrift. October 15th) finds that potassium permanganate acts not only as an astringent, but also as an antiseptic in cases of dysentery, and exerts a very favorable influence upon the inflamed and ulcerated mucous membrane. Enemata containing the salt give rise to a dull pain, but it is quite bearable and soon subsides. A one-to-two-thousand solution is used, and about two ounces, heated to 113° F., are injected slowly. The enema should be retained from half a minute to two minutes, and before it is employed the rectum should be washed out with warm water. The patient should keep perfectly quiet for an hour after each injection. For children the solution should be of the strength of one to five thousand, and for very young infants of one to ten thousand. This treatment is quite efficient for proctitis also.

Menthol and Orthoform in Laryngeal Tuberculosis.
—Freudenthal (Séméiologie; Fortschrifte der Medicin, October 4th) recommends the following mixture for allaying the pain:
R Menthol ................ 150 grains;
Orthoform ................ 188 “
Oil of sweet almonds ...... 450 “
Yolks of eggs .......... No. 2;
Distilled water, enough to make ................ 1,500 “
M.

The fauces and the rima gloticida are first anaesthetized with cocaine, and then a little of the emulsion is applied within the larynx. The soothing effect is said to be far greater than that of orthoform alone.
MYORRAPHY OF THE RECTI ABDOMINIS FOR EVENTRATION.

Such decided separation of the recti muscles of the abdomen as to allow of the escape of the abdominal viscerœ, constituting eventration, is, fortunately, among the rarer accidents of childbirth. When it does occur, it is apt to give rise to a great deal of suffering and disability, and palliative treatment by means of retentive apparatus is not usually very effective. The more radical procedure of uniting the two recti, drawn aside by the action of the obliqui, by means of suture seems to promise a practically perfect cure. In the Journal de médecine de Paris for September 3rd there is a translation, by Dr. J. Targowla, of Dr. A. A. Mouratof's account of a case in which he performed such an operation with entire success. The translation is not said to have been made from the author's manuscript, so we suppose the article was originally published in some Russian journal.

In this case the separation of the muscles was not noticed until the patient left her bed, on the fifth day after her delivery with the forceps. Labor had lasted thirty-six hours. It was five months later that the operation was performed, and at that time the evagination was complete, the abdominal organs lying immediately beneath the integument and being freely palpable as to all the details of their contour. The incision reached from less than an inch below the xiphoid cartilage down to the pubes. It was not an easy matter to find the inner edges of the recti, for those muscles had been drawn far apart by the action of the obliqui, and the recti themselves were very much attenuated. Their inner edges were refreshed and brought together with fine silk sutures inserted about a quarter of an inch apart. In addition, four heavy silk sutures were made to include both muscle and integument, but not the peritoneum. The last-named structure, indeed, was not opened at any time during the operation. Finally the skin was united by fine superficial sutures placed at a distance of about a quarter of an inch from each other. Iodoform gauze and tarlatan were applied, and over them several layers of adhesive plaster firmly supporting the abdomen. For seven days the patient was kept recumbent with her knees flexed (presumably also with the thighs flexed on the pelvis). The dressing was changed on the seventh day, and primary union was found to have taken place everywhere except at a point at the upper end of the wound. There was no elevation of temperature save on the third day, when it reached 101.1° F. The stitches were removed at various times from the ninth to the twelfth day, and the patient was allowed to leave her bed on the eleventh day. She was advised to wear an abdominal supporter for two or three months.

A year after the operation the patient became pregnant again, but abortion occurred at the end of two months and a half, without known cause. Two weeks after the abortion she presented nothing abnormal as concerns either the genital organs or the abdominal wall. There was no trace of evagination even when she made great efforts; the reunion of the two muscles was solid and durable, and there were no morbid phenomena whatever. Dr. Mouratof thinks that myorrhaphy of the recti is free from danger, although its performance calls for some delicacy in the case of lean subjects, in whom the muscles are very thin. Although he made use of silk sutures in the case reported, he now thinks it better to employ catgut, to prevent the formation of fistula. The after-treatment, he says, should be the same as in cases of laparotomy, the sutures should be removed gradually, beginning not sooner than the ninth day, and the patient should wear an abdominal bandage for two or three months.

A PLEA FOR GREATER BREADTH OF VIEW.

Two remarkable addresses have been delivered this year, remarkable in that they both came from men of prominence and standard professional reputation, and are both iconoclastic as regards one of the most firmly fixed ideas of modern medicine—viz., the specific germ causation of infective diseases. The first address was delivered by Dr. Granville Bantock before the British Gynæological Society on March 9th, and was published in abstract in the British Medical Journal for April 8th of this year. The second was by Dr. George Wilson (Lancet, August 5th), a prominent English medical officer of health, author of an admirable and widely used Handbook of Hygiene, and president of the Section of State Medicine at the annual meeting of the British Medical Association; and it was, moreover, delivered ex cathedra as his presidential address. The burden of both addresses was the same—that the micro-organisms whose constant presence has led to their being regarded
as specific causes of disease are associated with the
disease only because the disease provides the conditions
necessary for their free development—in other words,
their presence is the result, not the cause, of disease.
It would take too long to review here in detail the vari-
ous facts upon which these authors rest their opinions,
and it must be admitted that to uncritical inspection
they carry considerable weight; but they are all over-
come in every case where Koch's rules have been fully
complied with, viz., that a pure culture of the "asso-
ciated" germ, grown outside the body, must reproduce
the disease on introduction into the body of another ani-
mal, the same germ being then found in the animal so
inoculated.

But these addresses are not without great value for
all that, for they serve as notes of warning against any
extravagant pushing of theories. In our stubborn war
against the bad seed, we are in danger of losing sight
of the important part played by the soil in the process
of germination. Many years ago—in the days when the
identity of typhus and typhoid fevers, or their difference,
was still an open question, Dr. King Chambers, dis-
cussing in those admirable clinical lectures of his—mod-
els of straight thinking as they are—the subject of
"typh-fever," gave utterance to this sententious state-
ment: "For the act of poisoning to occur two things are
requisite—first, a poison, and secondly, a person apt
to be poisoned." In germs, in poisons, in medicines,
as in many other things, we have long been devoting
our attention too exclusively to the "poison" to the
neglect of the "person apt to be poisoned." The impor-
tance of the latter needs no illustration. There is the
wheat that will not grow on stony ground; there is the
opium-taker who has so prepared the soil that a wine-
glassful of laudanum will not kill him; there is the
person who goes freely among those stricken with in-
fected disease, and yet, though inevitably absorbing
the disease germs, does not contract the disease, either
because he has had it before or because he presents a
naturally unsuitable soil. Dr. Wilson says: "The bac-
teriologists so dominate the public press that we almost
seem to live in a bacillus-stricken world. . . . I venture
to say that the unconditional microbe need have no ter-
rors for humanity." It is just this dread of the "un-
conditional" microbe that will soon make life a misery
to man, until he will begin to feel that the only way to
avoid dying of the manifold perils that surround him is
to kill himself at once. The idea is being pushed so far
that one doubts whether it is safe to breathe at all, for
fear of inhaling the tubercle bacillus; to eat or drink,
from the risk of taking in the typhoid bacillus; while,
as to kissing the object of one's affection, it is fraught
with dangers too numerous to mention and too terrible
to contemplate. It was the dread of the "uncondi-
tional" microbe that led to the recent attempt to intro-
duce an impracticable tuberculosis quarantine in Cali-
fornia.

And whence comes all this distortion of harmony and
proportion? Surely from forgetting that the same laws
which hold good for the individual body hold good for
the body corporate. We should deride the man who
endeavored to get a knowledge of the liver from its
appearance under a sixteenth-of-an-inch oil-immersion
lens without ever having seen that viscus as a whole, or
any larger portion thereof than a microscopic section
affords; yet in all these questions affecting the macro-
 cosmos we are peering all the time through moral micro-
scopes and losing sight altogether of the sense of breadth
and proportion attainable only from a careful macro-
scopic observation before the object is submitted to a
lens at all. And the newspaper hysteries take our care-
less observations and our differing views, and with their
"crowd suggestion" drive bodies of otherwise sensible
men to hasty, impracticable, unjustifiable, undue re-
strictive legislation until it seems no longer safe to live.

SODIUM SALICYLATE IN THE TREATMENT
OF DIABETES.

The use of sodium salicylate in the treatment of
diabetes is not quite a novelty; in fact, its employment
in the iritis of diabetics has been recommended by a
number of writers. It is doubtful, however, if physi-
cians in general look upon the drug as capable of ful-
filling so many indications incident to the disease as
are brought forward by Dr. Litten (Therapie der Gegen-
wart, 1899, No. 3; Deutsche Aerzte-Zeitung, Septem-
ber 15th). He prescribes a tablespoonful of a four-
per-cent. solution to be taken every two or three hours,
and says that larger doses are quite unnecessary. He
finds that under the salicylate treatment the propor-
tion of sugar in the urine sinks one or two per cent.
almost always, but it is against a large number of the
"nervous" complications that the drug is mainly use-
ful. Especially brilliant, says Dr. Litten, is its action
in allaying the itching of diabetics and even in causing
the subsidence of the weeping eczema that is apt to
follow, although occasionally preparations of tar prove
efficient when the salicylate has failed. In neuralgic
complications, such as sciatica, intercostal neuralgia,
and zoster, the drug often proves highly efficient.

The author dwells particularly on the virtues of
sodium salicylate in decreasing the amount of urine secreted and abating the thirst, both of which symptoms he interprets as of nervous origin. This action of the salicylate, he says, is extraordinary in many cases. He cites the case of a child that had become very much reduced in the course of pronounced diabetes mellitus. A strict meat diet had had no effect on either the excretion of sugar, the distressing pruritus, the unquenchable thirst, or the enormous flow of urine. A teaspoonful of the solution given every three hours worked like a charm in relieving the itching, the thirst, and the polyuria, while the amount of sugar in the urine fell from five to less than three per cent. and the insatiable appetite was reduced.

It will be seen that Dr. Litten does not allege that sodium salicylate is to be regarded as curative of so serious a disease as diabetes mellitus, but, if his experience with it as a palliative proves to be that of most physicians who employ it in the treatment of that disease, a decided advance will have been made in the effort to prolong the lives of diabetics and to relieve them of much of their distress.

A REMARKABLE YARN ABOUT A JEALOUS DOCTOR.

On Thursday of last week the Mail and Express published an account of the case of a blind man, related by himself, who declared that some years before a certain physician who was at the time a friend of his had treated him for some eye trouble, but without success, whereupon another physician was called in. The second doctor was successful for a time, but eventually he, too, failed in the case, which went on to complete blindness. The first doctor, it is gravely asserted, confessed on his deathbed that out of jealousy he had surreptitiously drugged the ailing man in such a manner as to produce blindness! What a pity that he did not reveal the name of the drug!

AN ASTONISHING REVIVAL FROM ASPHYXIA NEONATORUM.
